3 29 **Abstract**
4

5 30 Wearable technology comprises miniaturized sensors (e.g. accelerometers) worn on the body
6
7 31 and/or paired with mobile devices (e.g. smart phones) allowing continuous patient monitoring in
8
9 32 unsupervised, habitual environments (termed free-living). Wearable technologies are revolutionising
10
11 33 approaches to healthcare due to their utility, accessibility and affordability. They are positioned to
12
13 34 transform Parkinson's disease (PD) management through provision of individualised, comprehensive,
14
15 35 and representative data. This is particularly relevant in PD where symptoms are often triggered by
16
17 36 task and free-living environmental challenges that cannot be replicated with sufficient veracity
18
19 37 elsewhere. This review concerns use of wearable technology in free-living environments for people
20
21 38 with PD. It outlines the potential advantages of wearable technologies and evidence for these to
22
23 39 accurately detect and measure clinically relevant features including motor symptoms, falls risk,
24
25 40 freezing of gait, gait, functional mobility and physical activity. Technological limitations and
26
27 41 challenges are highlighted and advances concerning broader aspects are discussed. Recommendations
28
29 42 to overcome key challenges are made. To date there is no fully validated system to monitor clinical
30
31 43 features or activities in free living environments. Robust accuracy and validity metrics for some
32
33 44 features have been reported, and wearable technology may be used in these cases with a degree of
34
35 45 confidence. Utility and acceptability appears reasonable, although testing has largely been informal.
36
37 46 Key recommendations include adopting a multi-disciplinary approach for standardising definitions,
38
39 47 protocols and outcomes. Robust validation of developed algorithms and sensor-based metrics is
40
41 48 required along with testing of utility. These advances are required before widespread clinical adoption
42
43
44 49 of wearable technology can be realised.

50 Introduction

51 Wearable technology and connected devices (WTCD) are positioned to become ubiquitous in
52 research and healthcare settings. WTCD comprise electronic technology worn on the body or
53 embedded into mobile phones, watches, bracelets, and clothing, amongst others. The generic appeal
54 of WTCD is obvious. Patient monitoring is free from contextual or environment barriers making
55 assessment at home and in the community over continuous time periods (termed free-living) feasible
56 and ecologically valid ¹. Moreover data are free from the confounds of observer bias and attentional
57 compensation associated with a one off testing session under observation ², while devices are
58 relatively low cost making their use economically as well as practically feasible.

59 The benefits of remote monitoring with WTCD are multi-fold. Clinically, continuous
60 monitoring of symptom severity and therapeutic response provides nuanced assessment. A complete
61 picture of disease burden is available both to the clinician and the patient incorporating a broad range
62 of features from the ‘*micro*’ level of detail (e.g. disease symptoms, medication response and
63 fluctuations, gait characteristics, turning, frequency of falls) through to more ‘*macro*’ levels (e.g.
64 habitual patterns of walking/activity, inactivity and sleep) (Figure 1). Enriched measurement, coupled
65 with ease of use, also has implications for industry, paving the way for identification of early disease
66 with the potential for enhanced diagnostic and progression markers (fundamental for trials of novel
67 therapeutics and disease modifying therapies), harmonisation of outcomes and standardized testing
68 protocols to enhance recruitment and assessment of treatments in clinical trials. For the patient,
69 WTCD offer insight into symptoms, therapeutic efficacy and habitual mobility in the context of
70 everyday life contributing to enhanced self-management that is both bespoke and contextualised.

71 Despite the recent explosion of low cost commercially available devices (for the general
72 population) promoting personal monitoring and feedback, the application of WTCD in healthcare has
73 not yet been established ³. The lure of utility (i.e. ease of use, broad application, and low cost) is
74 strong; however standards for clinical adoption and research application are far higher. While
75 technology and design have advanced, algorithm development and data analysis have not kept pace.
76 Validity and reliability are paramount and inform accurate detection and monitoring of disease and
77 this next step is critical before widespread adoption ⁴. Although there are promising signs, there is still

1
2
3 78 no single system/gold standard being used for remote monitoring^{5,6}. Therein lies both the opportunity
4
5 79 and the challenge.

6
7 80 This paper considers issues related to free-living monitoring from predominantly single
8
9 81 sensor-based devices (e.g. accelerometers and gyroscopes). We examine the ability of WCTD
10
11 82 algorithms to accurately detect a range of clinical features and report on criterion and discriminative
12
13 83 validity of outcomes derived from WCTD. Utility and feasibility are also considered. Clinical features
14
15 84 include monitoring of motor symptoms, medication response, sleep, falls and falls risk, freezing of
16
17 85 gait (FOG), gait, functional mobility and physical activity (ambulatory activity and sedentary
18
19 86 behaviour). This rapidly expanding field and has been the subject of a number of recent systematic
20
21 87 reviews⁷⁻⁹ including Sánchez-Ferro et al. within this issue to which the reader is referred. We have
22
23 88 therefore adopted a broader approach and provide a structured overview of the current status of
24
25 89 continuous patient monitoring in the home and community in Parkinson's disease (PD) which we
26
27 90 define as 'free-living'. We address four key aims: (1) the role and benefits of free-living monitoring;
28
29 91 (2) the validity and utility (acceptability and feasibility) of WTCD to monitor a range of key clinical
30
31 92 features relevant to PD; (3) critical challenges for adoption of WTCD for free-living assessment; and
32
33 93 (4) future developments in this rapidly developing field. Throughout we focus mainly on the
34
35 94 application of passive (no interaction from patient) single sensor-based devices and their application
36
37 95 in PD but where relevant draw from work in ageing cohorts. Finally, we make recommendations
38
39 96 based on this overview to progress free-living monitoring in PD.

40
41
42 97

43 98 **Does free-living monitoring confer an advantage over clinical assessment in PD?**

44
45 99 Due to its heterogeneity and complexity, clinical assessment of PD is challenging. The
46
47 100 intrinsic, fluctuating nature of PD and biphasic medication response in advanced disease requires
48
49 101 continuous evaluation over prolonged periods to gain an accurate picture of symptoms and their
50
51 102 fluctuations. The influence of attention on performance is well recognised especially with symptoms
52
53 103 such as FOG, leading to an inaccurate clinical picture^{2, 8}. Assessments requiring concentration and
54
55 104 recall such as falls diaries are further compromised by cognitive impairment, thus limiting utility.
56
57 105 Also, use of clinical scales is restrictive. The Unified Parkinson's Disease Rating Scale, (UPDRS)¹⁰,

1
2
3 106 although highly relevant to PD, is dependent on the patient's status at the time of assessment and
4
5 107 limited by subjectivity and clinical expertise. WTCD overcome many of these limitations by
6
7 108 objectively quantifying clinically relevant outcomes. Variation in testing is reduced^{3, 11, 12}. Patients
8
9 109 also have much to gain from this approach, with less emphasis during clinical visits on symptom
10
11 110 recall and evaluation of therapeutic response. Continuous monitoring also provides greater potential
12
13 111 for patient involvement in defining optimal management¹².

14
15 112 Measurement with WTCD is diverse. A single WTCD has the potential to provide the
16
17 113 clinician/researcher with a comprehensive picture of their patient within one assessment. For example,
18
19 114 Figure 1 shows that placement of a single sensor can quantify features such as volume and pattern of
20
21 115 habitual behaviours (e.g. walking, sleeping, sedentary time, Figure 1, A) (defined here as *macro*). The
22
23 116 raw signal (Figure 1, B) can then be further broken down to detect very discrete features (e.g. a fall,
24
25 117 gait characteristics, turning and freezing, figure 1, C-H) (defined here as *micro*). Taking this approach
26
27 118 enables multi-level measurement¹³.

28
29 119 <Figure 1>
30
31 120

32 33 121 **Free-living assessment of clinically relevant features in PD: a valid alternative to conventional** 34 35 122 **clinical assessment?**

36
37 123 Despite the obvious advantages of free-living assessment an important question remains – are
38
39 124 the outcome measures derived from WTCD suitable for current clinical use and will patients and
40
41 125 professionals use WTCD? Table 1, which form the basis of this section, provides an overview of
42
43 126 detection accuracy, validity and utility of some WTCD. Our main inclusion criterion was that WTCD
44
45 127 had been applied to free-living monitoring under either totally unsupervised or scripted protocol
46
47 128 conditions, with an exception made for studies where tests are conducted in formal settings to
48
49 129 optimise validation, such as detection of FOG. We report *criterion validity* from studies that examine
50
51 130 the association between WTCD-derived outcomes and other measures such as clinical scales. We also
52
53 131 report studies that test *discriminative validity*, which we define as the ability of WTCD-derived
54
55 132 outcomes to discern groups or phenotypes. The list is by no means exhaustive but provides a current
56
57 133 overview and highlights the vast interest in the area. We do not review static postural control despite
58
59
60

1
2
3 134 its obvious relevance to PD^{14,15}, because studies are laboratory and/or clinic based, however, facets of
4
5 135 postural control (e.g. dynamic, turning) are considered.
6

7 136

8
9 137 *Motor symptoms, medication response and sleep.* Continuous monitoring has a lot to offer over
10
11 138 snapshot clinical assessments which may not reveal the true extent of symptom burden. Earlier use of
12
13 139 WTCD for motor symptom measurement focused on evaluation of a single symptom to detect
14
15 140 hypokinesia, dyskinesia, tremor, bradykinesia, and akinesia derived on/off medication status^{16,17}.

16
17 141 This has evolved to assessment of multiple motor symptoms using either a single¹⁸⁻²⁰ or multiple
18
19 142 sensor systems^{17,21-24}. To date preliminary results are promising. Overall, motor symptom
20

21 143 measurement using WTCD is accurate and comparable with more established methods with some
22
23 144 aspects of validity tested. Criterion validity is established for most motor symptoms (tremor,
24

25 145 bradykinesia, dyskinesia) showing moderate to high correlations overall ($R > 0.65$) with standard
26
27 146 clinical scales (e.g. UPDRS, Abnormal Involuntary Movement Score (AIMS), Modified Bradykinesia
28

29 147 Rating Scale (MBRS), etc.) (see Table 1 for references). Measures of bradykinesia also show high
30
31 148 specificity (88%) and sensitivity (95%) when compared to standardised tests (e.g. the Dot Slide test)

32
33 149¹⁸. Studies that test discriminative validity are not as advanced, apart from the work by Horne et al.
34
35 150 which discerns motor symptom fluctuations in early stages of PD²⁰. Single sensors are sufficiently

36
37 151 robust for application, although there are question marks over aspects of utility for some systems
38
39 152 which require technical mastery and are demanding on the user (see 'Utility' section). Whilst there

40
41 153 have been a number of key developments in this area with motor symptom monitoring assessed at
42
43 154 home, the test protocols are still largely controlled and scripted as highlighted in table 1. True passive

44
45 155 monitoring without patient input is as yet an area to be developed but remains the area of greatest
46
47 156 interest as it will give the most ecologically valid picture of motor symptom burden and therapeutic

48
49 157 efficacy. Assessment of sleep also shows promise. WTCD-derived outcomes for sleep discriminate
50
51 158 PD from older adults (OA)^{25,26} for *macro* outcomes (e.g. number and size of movements) with people

52
53 159 with PD also showing increased episodes of nocturia, fewer turns during sleep, and greater arm
54
55 160 movements.
56

57
58 161
59
60

1
2
3 162 *Falls and falls risk.* Accurate detection of falls and falls risk (ideally before the first ever fall) would
4
5 163 greatly inform clinical management and therapeutic development and WTCD has a role to play. Real-
6
7 164 world detection of falls however is technically challenging. A plethora of algorithms, devices, and
8
9 165 device locations (chest, waist or wrist ²⁷⁻³¹) have been tested to improve the accuracy of falls
10
11 166 detection, however, studies are almost completely limited to controlled settings and conducted on
12
13 167 young healthy adults. Kangas et al. provides a rare example of using WTCD for falls detection in the
14
15 168 real-world where falls were measured in institutionalised OA and verified by an observer ³². Fall
16
17 169 detection sensitivity was 80% with a falls alarm rate per hour of 0.025, denoting one false alarm over
18
19 170 40 hours of recording. This points to high accuracy, although the testing environment was far
20
21 171 removed from 'free-living', and generalisability is therefore weak. Application in PD remains an area
22
23 172 of unmet need. An alternative approach is to predict falls risk using WTCD which, in contrast to falls
24
25 173 detection, is a more advanced field for both older adults and PD. Moreover, addressing a falls
26
27 174 prevention approach could be argued to have greater clinical relevance ^{33, 34}. Studies have compared
28
29 175 groups with and without falls in PD using free-living monitoring over 3-7 days. Falls risk factors
30
31 176 derived from gait during free-living walking bouts ^{33, 34} were superior to laboratory-based gait speed
32
33 177 and fall history to discriminate fallers from non-fallers ³⁵⁻³⁸. Discriminative validity has been
34
35 178 established for both *macro* and *micro* characteristics of gait and sedentary behaviour (Figure 1, A-B)
36
37 179 which are associated with type of PD fallers ³⁹ and fall history (fallers vs. non-fallers) in OA ^{38, 40} and
38
39 180 PD ⁴¹, respectively. *Micro* features may offer more than *macro* features ^{36, 37}, and contribute
40
41 181 substantially to predicting falls both in fallers and non-fallers ^{37, 38}. Further refinement of algorithm
42
43 182 and system development is however required to take the field forward.
44
45
46 183

47
48 184 *Freezing of gait.* Gait disturbances such as FOG are notoriously difficult to replicate in a controlled
49
50 185 environment because of its spontaneous nature and the non-specific and poorly understood triggers
51
52 186 that provoke it ³. Clinical scales such as the UPDRS and NFOG ⁴² are subjective and therefore
53
54 187 limited. Despite the obvious need, free-living monitoring of FOG in PD has not been achieved.
55
56 188 Detection of FOG episodes has been tested in controlled and structured conditions where FOG is
57
58
59
60

1
2
3 189 provoked during the ‘off’ condition, using either timed-up-and-go (TUG)⁴³ or walking tasks.⁴⁴
4
5 190 Studies show high sensitivity (range: 84.3%-86.2%) and moderate to high specificity (range 66.7%-
6
7 191 98.74%) for detection of FOG, and moderate agreement with clinical measures^{43, 44}. These results
8
9 192 provide a critical step from which validation can be extended to free-living. An alternative approach is
10
11 193 to identify potential predictors of FOG to understand the mechanisms and target therapeutic
12
13 194 developments. A recent study comparing freezers vs. non-freezers found frequency-based gait
14
15 195 characteristics collected during 3 days of free-living discriminated freezers. Gait characteristics were
16
17 196 also moderately correlated with clinical measures of FOG⁴⁵. Further work is needed before free-
18
19 197 living monitoring can be used for FOG detection or indeed for understanding the characteristics of
20
21 198 FOG but initial results are promising.
22
23 199
24
25 200 *Gait*. Measurement of gait per se (*micro* characteristics - Figure 1, E-F) is also of interest to the
26
27 201 clinician to evaluate efficacy of clinical management (due to dopa-resistance) as well as for its
28
29 202 potential for use of discrete gait characteristics as diagnostic, prognostic and progression markers⁴⁶⁻⁴⁸.
30
31 203 Gait assessment during free-living assessment also captures ongoing environmental and cognitive
32
33 204 challenges which impair gait performance. Assessment in this context has greater ecological validity
34
35 205 and gives a true picture of the burden of disease^{3, 7, 49}. Algorithms have been validated to detect
36
37 206 discrete gait characteristics in the laboratory and also in proxy validation studies⁵⁰⁻⁵⁵. Results showed
38
39 207 good agreement with trusted gold standard reference (e.g. GaitRite or optical motion capture systems)
40
41 208 for the majority of gait characteristics with potential advantages for asymmetry and variability
42
43 209 measures. Apart from Del Din et al.⁴⁹, the few studies that have examined gait in free living
44
45 210 conditions, quantify few gait characteristics⁵⁶⁻⁶¹. Discriminative validity has been tested, and has been
46
47 211 shown to discriminate between PD and OA^{49, 57}, phenotypes of PD⁶¹ and PD with higher or lower
48
49 212 cognitive functions⁶⁰. Aside from studies exploring falls and FOG risk highlighted previously⁵⁷ only
50
51 213 one study has investigated the effect of environment on gait. Free-living gait characteristics showed
52
53 214 better discriminative validity than those collected in the laboratory, especially for medium to long
54
55 215 bouts⁴⁹. Although initial work is promising, future work is required to confidently realise continuous
56
57 216 monitoring of gait. There are also some fundamental challenges to the field (outlined below).
58
59
60

217

218 *Measures of functional mobility.* Tests of functional mobility such as turning and Timed up and Go
219 (TUG) ⁶²⁻⁶⁴ measure combined movements that invariably incorporate postural transitions. Detection
220 of movements during functional mobility tasks appears accurate ^{62, 63, 65}, and validity (criterion and
221 discriminative) has been established by a limited number of studies ^{62, 65}. Mean turn velocity, slower
222 walking and turning, shorter steps and lower cadence distinguished PD from controls ^{62, 64} and also
223 showed greater sensitivity to dysfunction than clinical rating scales ^{64, 65}. Of interest, free-living
224 assessment appears to discriminate pathology better than testing in the laboratory ⁵⁴ (Figure 1, G).
225 Measurement of functional mobility tasks can therefore be undertaken with a degree of confidence
226 during a standardised test at home, although further work is required to replicate these findings.

227

228 *Ambulatory activity and sedentary behaviour.* One of the earliest applications of WTCD aimed to
229 quantify physical activity (e.g. ambulatory activity) amid rising concerns of the negative effects of
230 sedentary behaviour on well-being. This is particularly relevant for people with PD because of the
231 beneficial health benefits activity confers, and its role in mitigating secondary deficit. Ambulatory
232 activity provides a picture of the true burden of disease and therapeutic efficacy ⁶⁶. Proxy measures
233 such as activity logs and diaries are unreliable and lack responsiveness compared with continuous
234 WTCD monitoring ⁶⁷. Physical activity such as intensity of movement (energy expenditure), temporal
235 periods (bouts) of ambulatory activity (e.g. bouts of walking) and sedentary behaviours are quantified,
236 from which *macro* outcomes can be derived ^{66, 68-70} (Figure 1, A-B). The field has advanced further
237 with the application of non-linear approaches to data analysis which in some instances are more
238 sensitive than measures of central tendency (Table 1, Figure 2), such as pattern (alpha (α)) rather than
239 volume of sedentary behaviour showing discriminative properties ⁷¹. Ambulatory activity
240 differentiates disease stage ⁶⁶, and progression ^{72, 73} and shows increased sensitivity to intervention ^{68,}
241 ⁷⁴. Rochester et al. ⁶⁸ demonstrated the advantages of WTCD versus clinical measures when
242 examining the impact of deep brain stimulation (DBS) on ambulatory activity. Whilst standard
243 clinical measure for gait speed (4 meter test), levels of activity (Nottingham extended activities of
244 daily living index (NEADL)) and disease progression (Hoehn and Yahr) failed to show the positive

1
2
3 245 effects of DBS on the outcomes, WTCD-based measures demonstrated significantly improved
4
5 246 patterns of daily activity. Use of WTCD to measure ambulatory activity and sedentary behaviour is
6
7 247 the most advanced of all the fields discussed in this section, and the most widely adopted. Nonetheless
8
9 248 there are still questions over its application, driven by lack of common definitions of ambulatory
10
11 249 activity, validation procedures and structured protocols in controlled settings for validation of
12
13 250 algorithms⁶. These will be considered below.
14

15
16 251

17 252 *Utility and feasibility of WTCD: how acceptable are they?* Most studies do not intentionally test the
18
19 253 feasibility and utility of WTCD but instead draw on secondary data such as informal comments from
20
21 254 patients, reporting adverse events, data loss, or attrition in sensor use over the study period.
22
23 255 Importantly, there are no overwhelmingly negative reports, suggesting that WTCD are broadly
24
25 256 accepted. Although few studies have intentionally tested utility (which we describe as ‘formal testing’
26
27 257 in Table 1), some focused efforts have been made. Utility has been tested for wearable systems
28
29 258 comprising interactive⁷⁵ or multiple sensors^{17, 22, 23, 76}, using both non-standardised and standardised
30
31 259 questionnaires and rating scales²³ (e.g. the post-study usability questionnaire), comfort^{75, 76} (e.g.
32
33 260 comfort rating scale (CRS)) and ‘wearability’/exertion⁷⁶ (e.g. Borg CR-10 Scale, Rapid Entire Body
34
35 261 Assessment (REBA)). Overall the response has been positive, with WTCD generally well tolerated,
36
37 262 comfortable and easy to use. Compliance is high, although in some cases results were influenced by
38
39 263 socio-cultural aspects which may have positively biased results²³.
40

41
42 264

43
44 265 In summary, to date there is no fully validated WTCD system for continuous monitoring of patient
45
46 266 clinical features. Overall, studies are small, there is no consistent reporting of outcome measures,
47
48 267 protocols differ, and devices differ along with device placement. Comparison to a gold standard is
49
50 268 difficult. Knowledge on patient acceptability is limited. A clear process for validation including
51
52 269 replication in external data sets is essential with appropriate reporting according to a standard.
53
54 270 However the WTDC community is aware that this is an important and emerging area of research with
55
56 271 potential for high clinical uptake, and collaborative efforts are underway to redress these issues (see
57
58 272 reviews⁷⁻⁹). Challenges to implementation are due at least in part to broader technological and
59

1
2
3 273 practical concerns which are common to all WTCD and influence their state of readiness, irrespective
4
5 274 of application and use. Until these fundamental issues are redressed, robust use of WTCD will be
6
7 275 compromised. The next section highlights some of these broad concerns and discusses approaches to
8
9 276 advance the field.

10
11 277

12 13 278 **Challenges to clinical adoption**

14
15 279 We address 3 key areas fundamental to the use of WTCD that apply to all areas of
16
17 280 measurement: (i) clear definitions of the clinical feature of interest, (ii) validation of real-world data
18
19 281 and WTCD technical challenges, and (iii) consensus on outcomes. We illustrate these using examples
20
21 282 from our own experience in gait and activity and that of others (Figure 3). Finally we summarise
22
23 283 challenges with recommendations for future work and practical suggestions to inform the interested
24
25 284 user (Table 2).

26
27 285

28
29 286 *Defining the clinical feature.* Although on the face of it this seems simple, there are many examples
30
31 287 where unclear definitions have led to inconsistencies in outcomes and confusion when comparing
32
33 288 between studies. A good example relates to ambulatory activity, from which *macro* (e.g. walking
34
35 289 bouts) and *micro* level gait outcomes are derived that underpin many different clinical and research
36
37 290 questions (Figure 1). This stems from a basic definition of what constitutes a walking bout. In some
38
39 291 studies only purposeful bouts of walking are considered (with a cut-off threshold > 60 seconds)
40
41 292 because regular steady state is more likely to be achieved, thus avoiding potential errors in
42
43 293 misclassification from short bouts. However this is problematic because adults perform almost 90% of
44
45 294 walking bouts in less than 60s^{40, 49, 77} resulting in significant data loss and potentially missing the
46
47 295 most relevant data (such as change in variability of walking pattern). Another approach is to include
48
49 296 all bouts of walking⁴⁹ which is arguably more relevant in patient populations. However this is not a
50
51 297 complete solution because disagreement also exists regarding the number of steps required for a bout,
52
53 298 which may vary, ranging from >3 steps to >10 steps. As a consequence comparison across studies is
54
55 299 impossible where difference in step counts range from 2,000 to 10,000 steps^{66, 68, 72, 73}. The situation is
56
57 300 further complicated by the use of 'ghost' (unknown to the end user and hard-wired into WTCD)

1
2
3 301 thresholds used by the manufacturer to define consecutive bouts of walking that have a major impact
4
5 302 on *macro* outcomes ⁷⁸ (e.g. total number and pattern of walking bouts) (Figure 3, (1)). This uneven
6
7 303 approach significantly impacts on both *macro* and *micro* outcomes and therefore consensus as to a
8
9 304 clear definition of walking is urgently required ^{6, 78}. Attempts are underway to improve definitions
10
11 305 which will greatly help (Chastin et al.: ALPHABET: Development of A Physical Behaviour
12
13 306 Taxonomy with an international open consensus¹).

14
15 307

16
17 308 *Algorithm development, validation and technical challenges: Influence of context and protocol.*

18
19 309 Establishing a gold standard to test algorithm validity for the range of features highlighted in this
20
21 310 review during continuous uncontrolled monitoring in a free-living environment is a major challenge
22
23 311 without obvious solutions. Real-life is unpredictable and unstructured. For example, context
24
25 312 (environment and task) affects walking speed and direction which has implications for accuracy of
26
27 313 algorithms used to detect steps and phases of the gait cycle from which gait characteristics are
28
29 314 determined (Figure 3). Studies often adopt a number of different testing protocols and various sensor
30
31 315 configurations (type and location (upper or lower body, Table 1) which also impacts the signal
32
33 316 waveform influencing the accuracy of the algorithm used to extract micro outcomes and other type of
34
35 317 information (features, outcomes). Moreover algorithms are usually validated using healthy controls
36
37 318 data and adopted for analysing other groups' data (i.e. PD) without considering that speed (fast or
38
39 319 slow), pathology itself and disease stage may impact on the raw signal (Figure 3, (2)) and therefore
40
41 320 influence algorithm performance. In addition other technical considerations need to be taken into
42
43 321 account. Many commercial devices adopt black box designs with un-validated firmware/software ⁷⁹
44
45 322 which account for at least some of the significant disagreements in reported results ^{80, 81}. Other
46
47 323 uncertainties due to externally induced motion (e.g. cars, lifts) also impact on accuracy to detect
48
49 324 features of interest ⁸¹. Static and dynamic re-calibration of WTCD to account for possible axis
50
51 325 misalignment or sensor alterations due to damage (device dropped, contact with water etc.) is also
52
53 326 advised ⁸², however rarely undertaken because procedures are complicated and expensive. Further
54
55 327 sources of variability are also introduced through changes in external factors such as weather, mood

56
57
58 ¹ <https://osf.io/2wuv9/>

1
2
3 328 or medication, influencing analysis of the signal. Collectively these result in errors and decreased
4
5 329 confidence in outcomes and conformity to everyday use. Algorithm development will ultimately
6
7 330 refine extraction and a joint approach such as use of secondary data sources will aid interpretation, for
8
9 331 example data from patients' diaries, testimony from carers, and use of clinical records⁸³. All of these
10
11 332 potential sources of error should be considered and some suggestions are provided in Table 2.

12
13 333
14
15 334 *Determining optimal outcome measures.* Table 1 shows the vast range of outcomes reported.
16
17 335 Standardised measurement is urgently needed with a clear rationale for selection of outcomes from
18
19 336 which clinimetric testing will allow a refined battery of measures to emerge to encourage
20
21 337 harmonisation across studies. Examples of measurement frameworks have been described^{46, 49}
22
23 338 including our own *micro* and *macro* level structure used throughout this paper⁴⁷. Others^{37, 38, 45, 57, 61}
24
25 339 beside volume outcomes (e.g. total number of walking bouts, etc.) defined as '*quantity*' metrics, use
26
27 340 novel frequency-based outcomes to characterise gait (a) symmetry, variability and stability (e.g.
28
29 341 harmonic ratio, amplitude of dominant frequency, dynamic stability, etc.) defined broadly as '*quality*'
30
31 342 metrics. These novel *quality* measures, although very promising for discriminative validity, may be
32
33 343 difficult to interpret in clinical practice.

34
35 344

36
37 345 <Figure 2>

38
39 346 <Figure 3>

40
41 347

42 43 348 **Free-living monitoring in PD: where to next?**

44
45 349 Modern devices incorporate a range of inertial sensors such as accelerometers, gyroscopes,
46
47 350 magnetometers with Bluetooth connectivity which constitute cutting edge WTCD. While use is
48
49 351 currently limited to controlled settings, improvements in battery technology will improve the accuracy
50
51 352 of measurement addressing some of the challenges highlighted earlier. Moreover, novel methods for
52
53 353 advanced data processing are being developed to reduce computational load with advanced
54
55 354 computational processing carried out remotely via smartphone or in the cloud extending the
56
57 355 application of WTCD⁸⁴. Studies have also investigated the use of smart phones (and audio devices)

1
2
3 356 which regularly come with the necessary hardware to quantify symptoms, movement or gait⁸⁵. These
4
5 357 devices capture, analyse and relay information via cellular or other wireless networks and also provide
6
7 358 a more comprehensive assessment such as the addition of a microphone for use with speech analysis
8
9 359 algorithms in PD diagnosis^{86, 87} and visual displays to facilitate applications (apps) for the study of
10
11 360 cognition⁸⁸. Rigorous device testing however is needed to ensure confidence in their application.
12

13 361 Long term monitoring via a smart phone facilitates network interconnectivity and integration
14
15 362 to the Internet of Things (IoT)⁵, through delayed or real-time uploading of data to cloud computing
16
17 363 infrastructures. Data can be relayed to the patient (bio-feedback) via unobtrusive displays, haptic and
18
19 364 audible cues. Data is stored and sent to clinicians for tracking disease progression, optimising disease
20
21 365 management and providing further, more clinically informed feedback to the patient. Data storage and
22
23 366 data access on this scale constitutes 'big data analytics'. Developments in this field can expand
24
25 367 assessment to capture the 'lived experience' or 'livespace' of PD, capturing the extent to which people
26
27 368 travel and their patterns of movement within the community⁸⁹. This is exemplified by a recent
28
29 369 collaborative project between the Michael J. Fox Foundation and Apple utilising their projects,
30
31 370 FoxInsight² and the Apple ResearchKit³ (inc. the Parkinson mPower app⁴ available via iTunes),
32
33 371 respectively.
34

35 372 Collection of data on the scale and in a free-living context raises new ethical challenges with
36
37 373 respect to acquisition, analysis and storage. Current ethical reviews may not be sufficient to identify
38
39 374 modern issues⁹⁰. Technology and terminology has evolved faster than legal and ethical systems and
40
41 375 unforeseen issues can emerge⁹¹. Informed, principled, and collaborative experimentation are therefore
42
43 376 necessary to ensure privacy and confidentiality, and compliance with ethical principles.
44

45 377

46 378 **Conclusions and recommendations**

47
48
49 379 There is no doubting the possibilities and potential of real world monitoring and assessment
50
51 380 of clinical features for people with PD. It is conceivable to imagine a future where *micro* level data is
52
53 381 used to enhance diagnostics, measure efficacy of intervention and monitor disease progression, and

59
60

1
2
3 382 predict risk of disease, falls and cognitive decline. *Macro* level data, on the other hand, reflects the
4
5 383 global burden of disease and impact of therapy. Both sources of data provide insights into
6
7 384 personalised treatment. As this special issue in the journal indicates, this is a rapidly developing field.
8
9 385 However, much work remains before widespread clinical adoption is a reality. We highlight key
10
11 386 recommendations and some practical solutions to move this field forward (Table 2). These challenges
12
13 387 are likely to be met most effectively by adopting a multidisciplinary approach between key
14
15 388 stakeholders such as clinicians, patients, engineers, computer scientists, and statisticians.

Tables

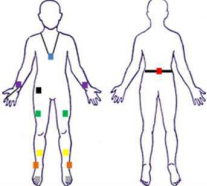

Table 1: Studies examining free-living monitoring of Parkinson’s disease (PD) using wearable technology and connected devices (WTCD). Number and position of WTCD used in each study is detailed in column two using a colour code (blue = chest, violet = wrist, black = pocket, green = thigh, yellow = shank, orange = ankle, grey = foot, red = lower back).

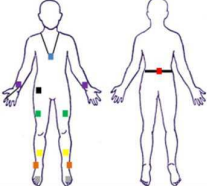

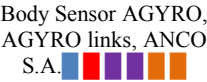

† Clinical feature/ activity detected or measures has been classified using three types of validity: 1) accurate detection of clinical feature/ method of appraisal: the ability of WCTD algorithms to accurately detect a clinical feature/activity which is comparable to detection by another means - in the study cited or previous studies (e.g. self-report, EMG); 2) criterion validity: the association between WTCD-derived outcomes and measures such as clinical scales; and 3) discriminative validity: the ability of WTCD-derived outcomes to discriminative between groups. Formal testing of utility (feasibility/compliance intentionally tested and reported) of WTCD is also reported.

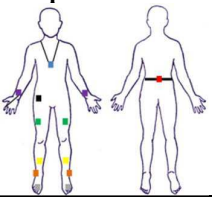

Study (Year), N, Length of recording	WTCD and placement	Clinical feature/ Activity	Accurate detection of clinical feature: Method of appraisal†	Measures	Criterion Validity†	Discriminative Validity†	Utility
<i>Motor symptoms and medication response</i>							
Das et al. (2012), 2 PD, 4*	Accelerometers 	Dyskinesia, tremor	Yes, against patients’ diaries using weakly supervised machine learning technique.	Acceleration derived features (Mean energy, high frequency energy content, correlation, frequency domain entropy)	No	No	No
Griffiths et al. (2012), 34 PD/10 OA, 10	Parkinson's KinetiGraph (PKG; Global Kinetics Corporation) 	Bradykinesia, dyskinesia	Yes, for bradykinesia against dot slide task measure (specificity 88%, sensitivity 95%) during scripted tests.	Acceleration derived features: Mean Spectral Power within specific bands, peak, amount of time with no movement	Yes, dyskinesia against the AIMS score and both dyskinesia and bradykinesia against UPDRS III and IV	No	No
Mera et al. (2012), 10 PD/ 10 OA, 3-6	Kinesia™ 	Motor tasks, tremor, bradykinesia, motor fluctuations	No	Symptoms severity scale (0-4 points), voluntary movement threshold evaluated with gyroscope derived features (RMS, peak of power spectrum)	Yes, for tremor and bradykinesia. Potential issues of recognition when the 2 symptoms overlap. Yes against videos in the lab for symptom severity scale validated against UPDRS tremor and MBRS speed, amplitude and rhythm scores in previous work ^{75, 92}	No	Yes, formal testing previous work ⁷⁵
Pastorino et al. (2013), 2 PD, 7	ALA-6g (PERFORM) 	Akinesia, ON/OFF state	Yes, 'proof of concept' validation	Level of akinesia	No	No	Yes, formal testing

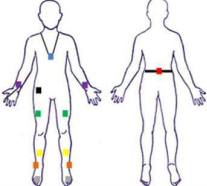

Study (Year), N, Length of recording	WTCD and placement 	Clinical feature/ Activity	Accurate detection of clinical feature: Method of appraisal†	Measures	Criterion Validity†	Discriminative Validity†	Utility
(but 32 hours analysed)			against patients' diaries				
Tzallas et al. (2014), 12 PD, 5 (8 hours per day)	ALA-6g (PERFORM) 	Tremor, LID, Bradykinesia, FOG	Yes, in the lab and during structured test (e.g. for FOG events Opening door/ Straight 10m walking) against video annotations.	Acceleration derived measures (time and frequency domains, RMS, range, entropy, energy)	Yes, machine learning and leave one out validation technique validated in the lab and applied in free-living conditions and compared against patients' diaries. Use of videos in the lab for assessing symptoms severity using UPDRS.	No	Yes, formal testing
Ferreira et al. (2015), 11 PD, 12 weeks	SENSE-PARK System 	Gait, hypokinesia, dyskinesia, tremor, sleep	No/NA (feasibility study and usability)	NA	NA	No	Yes, formal testing
Hammerla et al. (2015), 34 PD, 7	Axivity AX3 	Sleeping, ON/OFF state, dyskinesia	Yes, in the lab (against video recordings) using machine learning and leave one out validation technique, in free-living conditions results are compared against patients' diaries. Model pre-trained in free-living conditions did not give good results (laboratory data is a poor model for naturalistic behaviours)	Acceleration derived measures (magnitude, jerk, power spectral density, etc.)	No	No	Yes, formal testing but in subsequent work ⁹³
Horne et al. (2015), 64 PD/38 OA, 10	Parkinson's KinetiGraph (PKG; Global Kinetics Corporation) 	Bradykinesia, dyskinesia, fluctuations	Yes, against measures of bradykinesia and dyskinesia (previous work see Griffiths 2012)	Fluctuation Score based on Interquartile Range of bradykinesia and dyskinesia scores.	Yes, against clinical scores derived measure	Yes	No

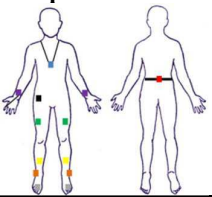

Study (Year), N, Length of recording	WTCD and placement 	Clinical feature/ Activity	Accurate detection of clinical feature: Method of appraisal†	Measures	Criterion Validity†	Discriminative Validity†	Utility
<i>Sleep</i>							
Prudon et al. (2013), 106 PD/99 OA, 3 nights	Acti-watch, Camntech 	Leg movements during sleep	Yes, in patients with periodic leg movement (against electromyography), previous work	Periodic leg movements index	Yes, against disease severity	No	No
Louter et al. (2015), 11 PD, 2 nights	Dynaport McRoberts 	Turning during sleep	Yes, against polysomnography in adults with obstructive sleep apnoea syndrome, previous work ⁹⁴	Acceleration derived measures (e.g. mean) and axial movement measures (frequency, size, duration, speed)	Yes, against Acti-watch but in young healthy adults previous work ⁹⁴	Yes	Yes, no formal testing, previous work
Sringean et al. (2015), 19 PD, 1 night	NIGHT-Recorder system 	Turning, Standing	No, video and sleep diaries collected but validity not formally tested.	Acceleration and gyroscope derived measures (duration of sleep, axial movements, velocity, etc.)	Yes, against clinical scores (UPDRS axial score, item #28, etc.)	Yes	Yes, no formal testing, no adverse events reported
<i>Falls and Falls Risk</i>							
Weiss et al. (2013), 71 OA, 3	Dynaport McRoberts 	Walking (at least 60s)	No	Number of walking bouts, walking duration, total number of steps, median number of steps per bout, bout duration, cadence, step and stride regularity, frequency domain measures (harmonic ratio, amplitude, slope and width of dominant frequency), step duration, step symmetry, acceleration range, etc.	Yes, against clinical scores of fall risk and laboratory based measures	Yes	No
Weiss et al. (2014), 107 PD, 3	Dynaport McRoberts 	Walking (at least 60s)	No	Number of walking bouts, % of activity duration, total number of steps, median number of steps per bout, bout duration, cadence, stride regularity, frequency domain measures (harmonic ratio,	Yes, against clinical scores of fall risk	Yes	Yes, no formal testing, data loss reported.

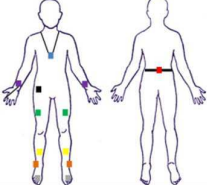

Study (Year), N, Length of recording	WTCD and placement 	Clinical feature/ Activity	Accurate detection of clinical feature: Method of appraisal†	Measures	Criterion Validity†	Discriminative Validity†	Utility
Brodie et al. (2015), 18 EF, 58 (average)	Senior Mobility Monitor (SMM, Philips) 	Walking (at least 3 or 8 steps)	No	amplitude and width of dominant frequency), etc. Steps per day, walking bouts per day, steps per bout, cadence, distribution of bout length	No	Yes	No
Hiorth et al. (2015), 48 PD, 7	activPAL 	Sedentary behaviour/ standing/ walking	Yes, but not formal in PD. Previous work in OA against other accelerometer ⁹⁵ and video recordings in people with rheumatoid arthritis during simulation of ADL in the laboratory ⁹⁶	Volume (e.g. total number of sedentary/standing/walking bouts), pattern (α), variability of sedentary bouts and number of strides per walking bout.	Yes, against clinical scores	Yes	No
Mactier et al. (2015), 111 PD, 7	activPAL 	Walking	Yes, but not formal in PD. Previous work in OA against other accelerometer ⁹⁵ and video recordings in people with rheumatoid arthritis during simulation of ADL in the laboratory ⁹⁶	Volume (e.g. total number of walking bouts), pattern (α), variability of bouts, accumulation of stepping bouts	No	Yes	No
Rispen et al. (2015), 113 OA, 14	Dynaport McRoberts 	Walking (at least 10s)	Yes, previous work in OA ⁹⁷ for walking volume parameters against videos, no for gait characteristics.	Acceleration based outcomes: gait speed, speed variability, stride time, stride regularity, stride time variability, stride frequency, frequency domain measures (harmonic ratio, amplitude, slope and width of dominant frequency), etc.	Yes, measures against self- reported fall history	No	No
van Schooten et al. (2015), 169 OA, 8	Dynaport McRoberts 	Walking (at least 10s), sitting, lying, and standing	Yes, previous work in OA ⁹⁷ for walking volume parameters against videos, no for	Total duration of walking, sitting, standing, and lying per day, number of	Yes, against falls history	Yes	No

Study (Year), N, Length of recording	WTCD and placement 	Clinical feature/ Activity	Accurate detection of clinical feature: Method of appraisal†	Measures	Criterion Validity†	Discriminative Validity†	Utility
			gait characteristics.	strides, number of walking bouts, duration of bouts, number of transitions. Gait characteristics: gait speed, stride frequency, stride length frequency domain measures (harmonic ratio, power at dominant frequency), etc.			
Kangas et al. (2015), 16 OA, 5-155		Falls‡	Yes, fall event against care personnel's reports and in previous work in OA during simulation of fall events in controlled conditions ⁹⁸ in OA	Fall event with alarm generation	No	No	Yes, based on alarm accuracy
<i>Freezing of Gait (FOG)</i>							
Moore et al. (2013), 25 PD, NA		Turning/ walking (TUG)‡	Yes, in the laboratory for FOG event against video recordings	FOG event through acceleration derived frequency measures (power spectrum, etc.).	No	No	No
Tripoliti et al. (2013), 11 PD/5 OA, NA		Walking, FOG detection‡	Yes, against video recordings and visual inspection during structured test (Opening door/ Straight 10m walking) using different classification algorithms and cross-validations	FOG detection through entropy of WTCD signal	No	No	No
Weiss et al. (2015), 72 PD, 3		Walking (at least 60s)	No	Number of walking bouts, % of activity duration, total number of steps, median number of steps per bout, bout duration, cadence, stride regularity, frequency domain	Yes, against clinical scores (FOG questionnaire)	Yes	No

Study (Year), N, Length of recording	WTCD and placement 	Clinical feature/ Activity	Accurate detection of clinical feature: Method of appraisal†	Measures	Criterion Validity†	Discriminative Validity†	Utility
				measures (harmonic ratio, width of dominant frequency), etc.			
<i>Gait</i>							
Cancela et al. (2011), 10 PD, 1 (not clear)	ALA-6g (PERFORM) 	Walking (on vs off medication)	Yes, only for step frequency during 10m scripted protocol against visual examination	Step frequency, stride length and speed, entropy, arm swing	No	Yes, only for entropy in previous work ⁹⁹	No
Weiss et al. (2011), 22 PD/17 OA (1PD/1CL at home), 3	Mobi8 	Walking (during scripted test in the lab and during simulation of ADL and free- living)	No	Acceleration derived measures (time and frequency domains): stride time, stride time variability, amplitude, width, slope of dominant frequency, etc.	Yes, against clinical scores	Yes	No
Cancela et al. (2014), 11 PD, 5-7 (8 hours per day)	ALA-6g (PERFORM) 	Walking	Yes, only for step frequency, previous work (see Cancela 2011)	Step frequency, step velocity, stride length, entropy	No	Yes, only for entropy in previous work ⁹⁹	Yes, formal testing and also assessed in separate study ⁷⁶
Herman et al. (2014), 110 PD, 3	Dynaport McRoberts 	Walking (at least 60s)	No	Total number of activity bouts, total % of activity duration, total number of steps, mean activity bout duration, median number of steps per bout, cadence, stride regularity, amplitude of dominant frequency, width of dominant frequency, stride regularity, harmonic ratio, Phase Coordination Index.	Yes, previous work	Yes, previous work	No.
Weiss et al. (2015), 107 PD, 3	Dynaport McRoberts 	Walking (at least 60s)	No	Total % of activity duration, total number of steps, cadence, amplitude of dominant frequency, stride regularity, harmonic ratio,	Yes, previous work	Yes, previous work	Yes, no formal testing, data loss reported

Study (Year), N, Length of recording	WTCD and placement 	Clinical feature/ Activity	Accurate detection of clinical feature: Method of appraisal†	Measures	Criterion Validity†	Discriminative Validity†	Utility
				<i>Phase Coordination Index.</i>			
Del Din et al. (2016), 47 PD/50 OA, 7	Axivity AX3 	Walking (at least 3 steps)	No	14 gait characteristics: mean step time, stance time, swing time, step length, step velocity, step time variability, stance time variability, swing time variability, step length variability, step velocity variability, step time asymmetry, stance time asymmetry, swing time asymmetry, step length asymmetry.	Yes, gait characteristics validated against laboratory reference (previous work ⁵³)	Yes	No
				<i>Timed-up-and-go (TUG)</i>			
Zampieri et al. (2011), 6 PD/8 OA, 1	Physilog 	Walking/turni ng/postural transitions †	Yes, in previous work ¹⁰⁰	Cadence, stride velocity, stride length, peak arm velocity, turning velocity	No	Yes	No
Smith et al. (2016), 12 OA, 5	SHIMMER 	Walking/turni ng †	No	Time to complete test, cadence, gait characteristics (step time, stride time, stride length, stride velocity, etc.), turning magnitude, etc.	No	No	No
				<i>Turning</i>			
El-Gohary et al. (2013), 12 PD/18 OA, 7*	Opal(ADPM)  in the lab / Opal(ADPM)   at home	Turning/ walking (at least 10s)	Yes, in the lab against motion analysis system and video recordings	Number of turns, peak velocity, mean velocity, duration of turn	No	Yes	No
Mancini et al. (2015), 13 PD/8 OA, 7*	Opal(ADPM)   	Turning/ walking (at least 10s)	Yes, in the lab (previous work, see El-Gohary 2013)	Number of turns/hour, turn angle, turn duration, number of steps/turn, turn mean velocity and coefficient of variation of these measures.	Yes	Yes	Yes, no formal testing, report of 'ease' of use.
				<i>Ambulatory activity and sedentary behaviour</i>

Rochester et al. (2012), 17 PD, 7	activPAL ■	Walking	Yes, but not formal in PD. Previous work in OA against other accelerometer ⁹⁵ and video recordings in	Volume of walking bouts, pattern of accumulation of bouts (GINI index) and diversity of bouts, distribution and variability of bouts (S ₂)	Yes	No	No

Study (Year), N, Length of recording	WTCD and placement 	Clinical feature/ Activity	Accurate detection of clinical feature: Method of appraisal†	Measures	Criterion Validity†	Discriminative Validity†	Utility
Lord et al. (2013), 89 PD/97 OA, 7	activPAL 	Walking	people with rheumatoid arthritis during simulation of ADL in the laboratory ⁹⁶ Yes, but not formal in PD. Previous work in OA against other accelerometer ⁹⁵ and video recordings in people with rheumatoid arthritis during simulation of ADL in the laboratory ⁹⁶	Volume of walking bouts, pattern (α), time spent walking in short-medium or long bouts, frequency and variability of bouts (S_2)	Yes	Yes	No
Cavanaugh et al. (2015), 17 PD, 7	StepWatch 3 Step Activity Monitor (SAM) 	Walking (average every 60s)	Yes, for stride count in PD against instrumented walkway in the lab, previous work (see Cavanaugh 2012)	Mean daily steps, maximum output for steps, Moderate intensity minutes (number of minutes with > 100 steps)	Yes	No	Yes, not formal testing, reasons for data loss and attrition in sensor acceptability after 2 years with decrease in participant use reported

ADL = Activities of Daily Living; Alpha = α ; Lab = Laboratory; Length of recording = number of weeks/days/minutes of recording; MBRS = Modified Bradykinesia Rating Scale; min = minutes; N = number of participants; OA = Older Adults; PD = Parkinson's disease; RMS = Root Mean Square; UPDRS = Unified Parkinson's Disease Rating Scale; % = Percentage; *Night excluded; † = scripted protocol/supervised conditions used.

Table 2: Practical solutions and broad recommendations for WTCD-related research challenges.

Recommendation	Practical solutions
Adopt standardised definition of activity/clinical feature	<ul style="list-style-type: none"> Justify definition of activity/clinical feature with respect to earlier work & clinical expertise. Adopt interdisciplinary collaboration for optimal process, choice of equipment, protocol, data processing and outcomes adhering to research question(s).
Select equipment depending on research/clinical question; evaluate trade-off between information needed & equipment available.	<ul style="list-style-type: none"> Consider optimal technical specifications (e.g. sampling frequency, type of data collected; battery life) for outcome measures. Use WTCD with established utility, acceptability and cost-effectiveness, otherwise plan to include tests of utility and acceptability as part of the study. Ensure transparency of all aspects of technology used (specifications, data collection, data pre-processing).
Use standardised protocols & validation procedures for algorithms for comparability & reproducibility across studies (e.g. accurate detection of activity/clinical feature, criterion & discriminative validity).	<ul style="list-style-type: none"> Justify use of standardised protocol & methods to define activities/clinical features. Use algorithms previously validated for the current application or provide validation results for novel algorithms. Use appropriate gold standards (e.g. video recording) to validate outcomes/metrics in free-living conditions, not limiting validation to scripted protocols or controlled conditions. Account for influence of context and disease severity on algorithm performance. If proprietary software is used ensure transparency of manufacturer algorithms or report published validated algorithm.
Achieve consensus for summary outcomes for comparability across studies.	<ul style="list-style-type: none"> Use WTCD-based outcomes validated in free-living; or provide validation results in the current study using semi-structured activities. Describe (if any) dependence of chosen summary outcomes & on chosen data processing/algorithm.

Figures

Figure 1:

Use of wearable technology and connected devices (WTCD) (adapted with permission from previous work)⁴⁷ A) *macro* level quantification of activities over an extended period of time (volume, patterns and variability); (B) bouts of activities (e.g. lying (sleeping), walking, sitting); (C-H) *micro* level quantification from specific events: C) and D) postural transitions, E) shuffling, F) gait, G) turning, H) freezing of gait (FOG) and fall.

Figure 2:

Examples of linear and non-linear approaches to activity data analysis: volume and pattern metrics for two subjects (Subject 1 and 2) (published with permission)⁶⁸.

A1 and A2 - Patterns of activity indicating bouts of sedentary, standing and walking at different stepping rates (cadences).

B1 and B2 - Volume Metrics: total walking time for the two subjects is equal but made up of walking bouts at different cadences.

C - Pattern Metrics: (i) and (ii) distribution of walking bouts for these two subjects with equal mean (M) and different dispersion (S2). C (iii) Accumulation pattern of walking time for subject 1 and 2; subject 2 tends to accumulate walking time with predominantly longer periods.

Figure 3:

Challenges/limitations of free-living measurement using examples from gait in free-living collected with a single accelerometer-based WTCD. Data (unpublished) from the Incidence of Cognitive Impairment in Cohorts with Longitudinal Evaluation-GAIT (ICICLE-GAIT) study¹⁰⁵.

Panel (1) – Definition of feature of interest (e.g. walking):

A) Impact of “selected” definition of walking on data processing: different threshold of walking bout length and (ghost) maximum resting period (MRP) between consecutive walking bouts can be utilised.

Examples: (i): use of walking bout threshold of 60s and no MRP (MRP = 0s) (only bouts longer than 60 s will be considered); (ii): use of walking bout threshold of 3 steps and no MRP (MRP = 0s); (iii) use of walking bout threshold of 3 steps and MRP = 5s.

B) Impact of choice in A) on *macro* outcomes (e.g. number of bouts considered, total number of steps reported for people with Parkinson’s disease (PD) and controls (CL)). For example using definition (i) only a small percentage of all the walking bouts will be considered (bouts > 60s only) and therefore fewer steps will be reported if compared to results of using definition (ii).

C) Impact of choice in A) on *micro* gait characteristics (e.g. reported step velocity may vary across studies due to choice of definition ((i), (ii) or (iii)).

Panel (2) – Influence of free-living protocol on data:

Walking speed changes with respect to the environment, task, and disease severity which influences the accelerometer raw signal (D) impacting on algorithm performance and evaluation of outcomes (E).

Use of wearable technology and connected devices (WTCD) (adapted with permission from previous work)

47 A) macro level quantification of activities over an extended period of time (volume, patterns and variability); (B) bouts of activities (e.g. lying (sleeping), walking, sitting); (C-H) micro level quantification from specific events: C) and D) postural transitions, E) shuffling, F) gait, G) turning, H) freezing of gait (FOG) and fall.

181x269mm (300 x 300 DPI)

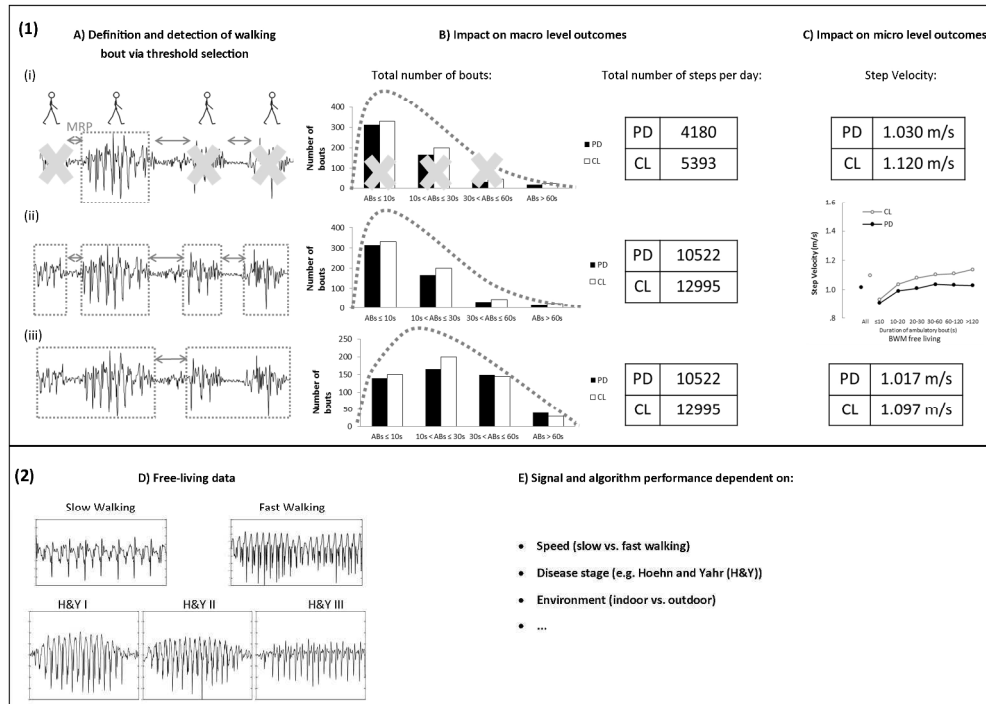

Examples of linear and non-linear approaches to activity data analysis: volume and pattern metrics for two subjects (Subject 1 and 2) (published with permission) 68.

A1 and A2 - Patterns of activity indicating bouts of sedentary, standing and walking at different stepping rates (cadences).

B1 and B2 - Volume Metrics: total walking time for the two subjects is equal but made up of walking bouts at different cadences.

C - Pattern Metrics: (i) and (ii) distribution of walking bouts for these two subjects with equal mean (M) and different dispersion (S_2). C (iii) Accumulation pattern of walking time for subject 1 and 2; subject 2 tends to accumulate walking time with predominantly longer periods.

188x78mm (300 x 300 DPI)

Challenges/limitations of free-living measurement using examples from gait in free-living collected with a single accelerometer-based WTCD. Data (unpublished) from the Incidence of Cognitive Impairment in Cohorts with Longitudinal Evaluation-GAIT (ICICLE-GAIT) study 106.

Panel (1) – Definition of feature of interest (e.g. walking):

A) Impact of “selected” definition of walking on data processing: different threshold of walking bout length and (ghost) maximum resting period (MRP) between consecutive walking bouts can be utilised. Examples: (i): use of walking bout threshold of 60s and no MRP (MRP = 0s) (only bouts longer than 60 s will be considered); (ii): use of walking bout threshold of 3 steps and no MRP (MRP = 0s); (iii) use of walking bout threshold of 3 steps and MRP = 5s.

B) Impact of choice in A) on macro outcomes (e.g. number of bouts considered, total number of steps reported for people with Parkinson’s disease (PD) and controls (CL)). For example using definition (i) only a small percentage of all the walking bouts will be considered (bouts > 60s only) and therefore fewer steps will be reported if compared to results of using definition (ii).

C) Impact of choice in A) on micro gait characteristics (e.g. reported step velocity may vary across studies due to choice of definition ((i), (ii) or (iii)).

Panel (2) – Influence of free-living protocol on data:

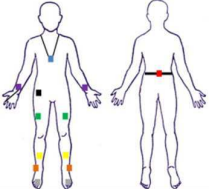

Walking speed changes with respect to the environment, task, and disease severity which influences the accelerometer raw signal (D) impacting on algorithm performance and evaluation of outcomes (E).
275x197mm (300 x 300 DPI)

Table 1

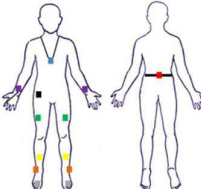

Table 1: Studies examining free-living monitoring of Parkinson’s disease (PD) using wearable technology and connected devices (WTCD). Number and position of WTCD used in each study is detailed in column two using a colour code (blue = chest, violet = wrist, black = pocket, green = thigh, yellow = shank, orange = ankle, grey = foot, red = lower back).

† Clinical feature/ activity detected or measures has been classified using three types of validity: 1) accurate detection of clinical feature/ method of appraisal: the ability of WCTD algorithms to accurately detect a clinical feature/activity which is comparable to detection by another means - in the study cited or previous studies (e.g. self-report, EMG); 2) criterion validity: the association between WTCD-derived outcomes and measures such as clinical scales; and 3) discriminative validity: the ability of WTCD-derived outcomes to discriminative between groups. Formal testing of utility (feasibility/compliance intentionally tested and reported) of WTCD is also reported.

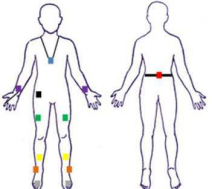

Study (Year), N, Length of recording	WTCD and placement 	Clinical feature/ Activity	Accurate detection of clinical feature: Method of appraisal†	Measures	Criterion Validity†	Discriminative Validity†	Utility
<i>Motor symptoms and medication response</i>							
Das et al. (2012), 2 PD, 4*	Accelerometers 	Dyskinesia, tremor	Yes, against patients’ diaries using weakly supervised machine learning technique.	Acceleration derived features (Mean energy, high frequency energy content, correlation, frequency domain entropy)	No	No	No
Griffiths et al. (2012), 34 PD/10 OA, 10	Parkinson's KinetiGraph (PKG; Global Kinetics Corporation) 	Bradykinesia, dyskinesia	Yes, for bradykinesia against dot slide task measure (specificity 88%, sensitivity 95%) during scripted tests.	Acceleration derived features: Mean Spectral Power within specific bands, peak, amount of time with no movement	Yes, dyskinesia against the AIMS score and both dyskinesia and bradykinesia against UPDRS III and IV	No	No
Mera et al. (2012), 10 PD/ 10 OA, 3-6	Kinesia™ 	Motor tasks, tremor, bradykinesia, motor fluctuations	No	Symptoms severity scale (0-4 points), voluntary movement threshold evaluated with gyroscope derived features (RMS, peak of power spectrum)	Yes, for tremor and bradykinesia. Potential issues of recognition when the 2 symptoms overlap. Yes against videos in the lab for symptom severity scale validated against UPDRS tremor and MBRS speed, amplitude and	No	Yes, formal testing previous work ⁷⁵

Study (Year), N, Length of recording	WTCD and placement 	Clinical feature/ Activity	Accurate detection of clinical feature: Method of appraisal†	Measures	Criterion Validity†	Discriminative Validity†	Utility
Pastorino et al. (2013), 2 PD, 7 (but 32 hours analysed)	ALA-6g (PERFORM) 	Akinesia, ON/OFF state	Yes, 'proof of concept' validation against patients' diaries	Level of akinesia	No	No	Yes, formal testing
Tzallas et al. (2014), 12 PD, 5 (8 hours per day)	ALA-6g (PERFORM) 	Tremor, LID, Bradykinesia, FOG	Yes, in the lab and during structured test (e.g. for FOG events Opening door/ Straight 10m walking) against video annotations.	Acceleration derived measures (time and frequency domains, RMS, range, entropy, energy)	Yes, machine learning and leave one out validation technique validated in the lab and applied in free-living conditions and compared against patients' diaries. Use of videos in the lab for assessing symptoms severity using UPDRS.	No	Yes, formal testing
Ferreira et al. (2015), 11 PD, 12 weeks	SENSE-PARK System 	Gait, hypokinesia, dyskinesia, tremor, sleep	No/NA (feasibility study and usability)	NA	NA	No	Yes, formal testing
Hammerla et al. (2015), 34 PD, 7	Axivity AX3 	Sleeping, ON/OFF state, dyskinesia	Yes, in the lab (against video recordings) using machine learning and leave one out validation technique, in free-living conditions results are compared against patients' diaries. Model pre-trained in free-living conditions did not give good	Acceleration derived measures (magnitude, jerk, power spectral density, etc.)	No	No	Yes, formal testing but in subsequent work ⁹³

Study (Year), N, Length of recording	WTCD and placement 	Clinical feature/ Activity	Accurate detection of clinical feature: Method of appraisal†	Measures	Criterion Validity†	Discriminative Validity†	Utility
			results (laboratory data is a poor model for naturalistic behaviours)				
Horne et al. (2015), 64 PD/38 OA, 10	Parkinson's KinetiGraph (PKG; Global Kinetics Corporation) 	Bradykinesia, dyskinesia, fluctuations	Yes, against measures of bradykinesia and dyskinesia (previous work see Griffiths 2012)	Fluctuation Score based on Interquartile Range of bradykinesia and dyskinesia scores.	Yes, against clinical scores derived measure	Yes	No
<i>Sleep</i>							
Prudon et al. (2013), 106 PD/99 OA, 3 nights	Acti-watch, Camntech 	Leg movements during sleep	Yes, in patients with periodic leg movement (against electromyography), previous work	Periodic leg movements index	Yes, against disease severity	No	No
Louter et al. (2015), 11 PD, 2 nights	Dynaport McRoberts 	Turning during sleep	Yes, against polysomnography in adults with obstructive sleep apnoea syndrome, previous work ⁹⁴	Acceleration derived measures (e.g. mean) and axial movement measures (frequency, size, duration, speed)	Yes, against Acti-watch but in young healthy adults previous work ⁹⁴	Yes	Yes, no formal testing, previous work
Sringean et al. (2015), 19 PD, 1 night	NIGHT-Recorder system 	Turning, Standing	No, video and sleep diaries collected but validity not formally tested.	Acceleration and gyroscope derived measures (duration of sleep, axial movements, velocity, etc.)	Yes, against clinical scores (UPDRS axial score, item #28, etc.)	Yes	Yes, no formal testing, no adverse events reported
<i>Falls and Falls Risk</i>							
Weiss et al. (2013), 71 OA, 3	Dynaport McRoberts 	Walking (at least 60s)	No	Number of walking bouts, walking duration, total number of steps, median number of steps per bout, bout duration, cadence, step	Yes, against clinical scores of fall risk and laboratory based measures	Yes	No

3 29 **Abstract**
4

5 30 Wearable technology comprises miniaturized sensors (e.g. accelerometers) worn on the body
6
7 31 and/or paired with mobile devices (e.g. smart phones) allowing continuous patient monitoring in
8
9 32 unsupervised, habitual environments (termed free-living). Wearable technologies are revolutionising
10
11 33 approaches to healthcare due to their utility, accessibility and affordability. They are positioned to
12
13 34 transform Parkinson's disease (PD) management through provision of individualised, comprehensive,
14
15 35 and representative data. This is particularly relevant in PD where symptoms are often triggered by
16
17 36 task and free-living environmental challenges that cannot be replicated with sufficient veracity
18
19 37 elsewhere. This review concerns use of wearable technology in free-living environments for people
20
21 38 with PD. It outlines the potential advantages of wearable technologies and evidence for these to
22
23 39 accurately detect and measure clinically relevant features including motor symptoms, falls risk,
24
25 40 freezing of gait, gait, functional mobility and physical activity. Technological limitations and
26
27 41 challenges are highlighted and advances concerning broader aspects are discussed. Recommendations
28
29 42 to overcome key challenges are made. To date there is no fully validated system to monitor clinical
30
31 43 features or activities in free living environments. Robust accuracy and validity metrics for some
32
33 44 features have been reported, and wearable technology may be used in these cases with a degree of
34
35 45 confidence. Utility and acceptability appears reasonable, although testing has largely been informal.
36
37 46 Key recommendations include adopting a multi-disciplinary approach for standardising definitions,
38
39 47 protocols and outcomes. Robust validation of developed algorithms and sensor-based metrics is
40
41 48 required along with testing of utility. These advances are required before widespread clinical adoption
42
43
44 49 of wearable technology can be realised.

50 Introduction

51 Wearable technology and connected devices (WTCD) are positioned to become ubiquitous in
52 research and healthcare settings. WTCD comprise electronic technology worn on the body or
53 embedded into mobile phones, watches, bracelets, and clothing, amongst others. The generic appeal
54 of WTCD is obvious. Patient monitoring is free from contextual or environment barriers making
55 assessment at home and in the community over continuous time periods (termed free-living) feasible
56 and ecologically valid ¹. Moreover data are free from the confounds of observer bias and attentional
57 compensation associated with a one off testing session under observation ², while devices are
58 relatively low cost making their use economically as well as practically feasible.

59 The benefits of remote monitoring with WTCD are multi-fold. Clinically, continuous
60 monitoring of symptom severity and therapeutic response provides nuanced assessment. A complete
61 picture of disease burden is available both to the clinician and the patient incorporating a broad range
62 of features from the '*micro*' level of detail (e.g. disease symptoms, medication response and
63 fluctuations, gait characteristics, turning, frequency of falls) through to more '*macro*' levels (e.g.
64 habitual patterns of walking/activity, inactivity and sleep) (Figure 1). Enriched measurement, coupled
65 with ease of use, also has implications for industry, paving the way for identification of early disease
66 with the potential for enhanced diagnostic and progression markers (fundamental for trials of novel
67 therapeutics and disease modifying therapies), harmonisation of outcomes and standardized testing
68 protocols to enhance recruitment and assessment of treatments in clinical trials. For the patient,
69 WTCD offer insight into symptoms, therapeutic efficacy and habitual mobility in the context of
70 everyday life contributing to enhanced self-management that is both bespoke and contextualised.

71 Despite the recent explosion of low cost commercially available devices (for the general
72 population) promoting personal monitoring and feedback, the application of WTCD in healthcare has
73 not yet been established ³. The lure of utility (i.e. ease of use, broad application, and low cost) is
74 strong; however standards for clinical adoption and research application are far higher. While
75 technology and design have advanced, algorithm development and data analysis have not kept pace.
76 Validity and reliability are paramount and inform accurate detection and monitoring of disease and
77 this next step is critical before widespread adoption ⁴. Although there are promising signs, there is still

1
2
3 78 no single system/gold standard being used for remote monitoring^{5,6}. Therein lies both the opportunity
4
5 79 and the challenge.

6
7 80 This paper considers issues related to free-living monitoring from predominantly single
8
9 81 sensor-based devices (e.g. accelerometers and gyroscopes). We examine the ability of WCTD
10
11 82 algorithms to accurately detect a range of clinical features and report on criterion and discriminative
12
13 83 validity of outcomes derived from WCTD. Utility and feasibility are also considered. Clinical features
14
15 84 include monitoring of motor symptoms, medication response, sleep, falls and falls risk, freezing of
16
17 85 gait (FOG), gait, functional mobility and physical activity (ambulatory activity and sedentary
18
19 86 behaviour). This rapidly expanding field and has been the subject of a number of recent systematic
20
21 87 reviews⁷⁻⁹ including Sánchez-Ferro et al. within this issue to which the reader is referred. We have
22
23 88 therefore adopted a broader approach and provide a structured overview of the current status of
24
25 89 continuous patient monitoring in the home and community in Parkinson's disease (PD) which we
26
27 90 define as 'free-living'. We address four key aims: (1) the role and benefits of free-living monitoring;
28
29 91 (2) the validity and utility (acceptability and feasibility) of WTCd to monitor a range of key clinical
30
31 92 features relevant to PD; (3) critical challenges for adoption of WTCd for free-living assessment; and
32
33 93 (4) future developments in this rapidly developing field. Throughout we focus mainly on the
34
35 94 application of passive (no interaction from patient) single sensor-based devices and their application
36
37 95 in PD but where relevant draw from work in ageing cohorts. Finally, we make recommendations
38
39 96 based on this overview to progress free-living monitoring in PD.

40
41
42 97

43 98 **Does free-living monitoring confer an advantage over clinical assessment in PD?**

44
45 99 Due to its heterogeneity and complexity, clinical assessment of PD is challenging. The
46
47 100 intrinsic, fluctuating nature of PD and biphasic medication response in advanced disease requires
48
49 101 continuous evaluation over prolonged periods to gain an accurate picture of symptoms and their
50
51 102 fluctuations. The influence of attention on performance is well recognised especially with symptoms
52
53 103 such as FOG, leading to an inaccurate clinical picture^{2, 8}. Assessments requiring concentration and
54
55 104 recall such as falls diaries are further compromised by cognitive impairment, thus limiting utility.
56
57 105 Also, use of clinical scales is restrictive. The Unified Parkinson's Disease Rating Scale, (UPDRS)¹⁰,

1
2
3 106 although highly relevant to PD, is dependent on the patient's status at the time of assessment and
4
5 107 limited by subjectivity and clinical expertise. WTCD overcome many of these limitations by
6
7 108 objectively quantifying clinically relevant outcomes. Variation in testing is reduced^{3, 11, 12}. Patients
8
9 109 also have much to gain from this approach, with less emphasis during clinical visits on symptom
10
11 110 recall and evaluation of therapeutic response. Continuous monitoring also provides greater potential
12
13 111 for patient involvement in defining optimal management¹².

14
15 112 Measurement with WTCD is diverse. A single WTCD has the potential to provide the
16
17 113 clinician/researcher with a comprehensive picture of their patient within one assessment. For example,
18
19 114 Figure 1 shows that placement of a single sensor can quantify features such as volume and pattern of
20
21 115 habitual behaviours (e.g. walking, sleeping, sedentary time, Figure 1, A) (defined here as *macro*). The
22
23 116 raw signal (Figure 1, B) can then be further broken down to detect very discrete features (e.g. a fall,
24
25 117 gait characteristics, turning and freezing, figure 1, C-H) (defined here as *micro*). Taking this approach
26
27 118 enables multi-level measurement¹³.

28
29 119 <Figure 1>
30
31 120

32 33 121 **Free-living assessment of clinically relevant features in PD: a valid alternative to conventional** 34 35 122 **clinical assessment?**

36
37 123 Despite the obvious advantages of free-living assessment an important question remains – are
38
39 124 the outcome measures derived from WTCD suitable for current clinical use and will patients and
40
41 125 professionals use WTCD? Table 1, which form the basis of this section, provides an overview of
42
43 126 detection accuracy, validity and utility of some WTCD. Our main inclusion criterion was that WTCD
44
45 127 had been applied to free-living monitoring under either totally unsupervised or scripted protocol
46
47 128 conditions, with an exception made for studies where tests are conducted in formal settings to
48
49 129 optimise validation, such as detection of FOG. We report *criterion validity* from studies that examine
50
51 130 the association between WTCD-derived outcomes and other measures such as clinical scales. We also
52
53 131 report studies that test *discriminative validity*, which we define as the ability of WTCD-derived
54
55 132 outcomes to discern groups or phenotypes. The list is by no means exhaustive but provides a current
56
57 133 overview and highlights the vast interest in the area. We do not review static postural control despite
58
59
60

1
2
3 134 its obvious relevance to PD ^{14, 15}, because studies are laboratory and/or clinic based, however, facets of
4
5 135 postural control (e.g. dynamic, turning) are considered.
6

7 136

8
9 137 **Motor** symptoms, medication response and sleep. Continuous monitoring has a lot to offer over
10
11 138 snapshot clinical assessments which may not reveal the true extent of symptom burden. Earlier use of
12
13 139 WTCD for **motor** symptom measurement focused on evaluation of a single symptom to detect
14
15 140 hypokinesia, dyskinesia, tremor, bradykinesia, and akinesia derived on/off medication status ^{16, 17}.

16
17 141 This has evolved to assessment of multiple **motor** symptoms using either a single ¹⁸⁻²⁰ or multiple
18
19 142 sensor systems ^{17, 21-24}. To date preliminary results are promising. Overall, **motor** symptom
20

21 143 measurement using WTCD is accurate and comparable with more established methods with some
22
23 144 aspects of validity tested. **Criterion validity is established for most motor symptoms (tremor,**

24
25 145 **bradykinesia, dyskinesia) showing moderate to high correlations overall (R > 0.65) with standard**
26
27 146 **clinical scales (e.g. UPDRS, Abnormal Involuntary Movement Score (AIMS), Modified Bradykinesia**

28
29 147 **Rating Scale (MBRS), etc.) (see Table 1 for references). Measures of bradykinesia also show high**
30
31 148 **specificity (88%) and sensitivity (95%) when compared to standardised tests (e.g. the Dot Slide test)**

32
33 149 **¹⁸. Studies that test discriminative validity are not as advanced,** apart from the work by Horne et al.
34
35 150 which discerns **motor** symptom fluctuations in early stages of PD ²⁰. Single sensors are sufficiently

36
37 151 robust for application, although there are question marks over aspects of utility for some systems
38
39 152 which require technical mastery and are demanding on the user (see 'Utility' section). Whilst there

40
41 153 have been a number of key developments in this area with **motor** symptom monitoring assessed at
42
43 154 home, the test protocols are still largely controlled and scripted as highlighted in table 1. True passive

44
45 155 monitoring without patient input is as yet an area to be developed but remains the area of greatest
46
47 156 interest as it will give the most ecologically valid picture of **motor** symptom burden and therapeutic

48
49 157 efficacy. Assessment of sleep also shows promise. WTCD-derived outcomes for sleep discriminate
50
51 158 PD from older adults (OA) ^{25, 26} for *macro* outcomes (e.g. number and size of movements) with people

52
53 159 with PD also showing increased episodes of nocturia, fewer turns during sleep, and greater arm
54
55 160 movements.
56

57
58 161
59
60

1
2
3 162 *Falls and falls risk.* Accurate detection of falls and falls risk (ideally before the first ever fall) would
4
5 163 greatly inform clinical management and therapeutic development and WTCD has a role to play. Real-
6
7 164 world detection of falls however is technically challenging. A plethora of algorithms, devices, and
8
9 165 device locations (chest, waist or wrist ²⁷⁻³¹) have been tested to improve the accuracy of falls
10
11 166 detection, however, studies are almost completely limited to controlled settings and conducted on
12
13 167 young healthy adults. Kangas et al. provides a rare example of using WTCD for falls detection in the
14
15 168 real-world where falls were measured in institutionalised OA and verified by an observer ³². Fall
16
17 169 detection sensitivity was 80% with a falls alarm rate per hour of 0.025, denoting one false alarm over
18
19 170 40 hours of recording. This points to high accuracy, although the testing environment was far
20
21 171 removed from 'free-living', and generalisability is therefore weak. Application in PD remains an area
22
23 172 of unmet need. An alternative approach is to predict falls risk using WTCD which, in contrast to falls
24
25 173 detection, is a more advanced field for both older adults and PD. Moreover, addressing a falls
26
27 174 prevention approach could be argued to have greater clinical relevance ^{33, 34}. Studies have compared
28
29 175 groups with and without falls in PD using free-living monitoring over 3-7 days. Falls risk factors
30
31 176 derived from gait during free-living walking bouts ^{33, 34} were superior to laboratory-based gait speed
32
33 177 and fall history to discriminate fallers from non-fallers ³⁵⁻³⁸. Discriminative validity has been
34
35 178 established for both *macro* and *micro* characteristics of gait and sedentary behaviour (Figure 1, A-B)
36
37 179 which are associated with type of PD fallers ³⁹ and fall history (fallers vs. non-fallers) in OA ^{38, 40} and
38
39 180 PD ⁴¹, respectively. *Micro* features may offer more than *macro* features ^{36, 37}, and contribute
40
41 181 substantially to predicting falls both in fallers and non-fallers ^{37, 38}. Further refinement of algorithm
42
43 182 and system development is however required to take the field forward.
44
45
46 183

47
48 184 *Freezing of gait.* Gait disturbances such as FOG are notoriously difficult to replicate in a controlled
49
50 185 environment because of its spontaneous nature and the non-specific and poorly understood triggers
51
52 186 that provoke it ³. Clinical scales such as the UPDRS and NFOG ⁴² are subjective and therefore
53
54 187 limited. Despite the obvious need, free-living monitoring of FOG in PD has not been achieved.
55
56 188 Detection of FOG episodes has been tested in controlled and structured conditions where FOG is
57
58
59
60

1
2
3 189 provoked during the ‘off’ condition, using either timed-up-and-go (TUG) ⁴³ or walking tasks. ⁴⁴
4
5 190 Studies show high sensitivity (range: 84.3%-86.2%) and moderate to high specificity (range 66.7%-
6
7 191 98.74%) for detection of FOG, and moderate agreement with clinical measures ^{43, 44}. These results
8
9 192 provide a critical step from which validation can be extended to free-living. An alternative approach is
10
11 193 to identify potential predictors of FOG to understand the mechanisms and target therapeutic
12
13 194 developments. A recent study comparing freezers vs. non-freezers found frequency-based gait
14
15 195 characteristics collected during 3 days of free-living discriminated freezers. Gait characteristics were
16
17 196 also moderately correlated with clinical measures of FOG ⁴⁵. Further work is needed before free-
18
19 197 living monitoring can be used for FOG detection or indeed for understanding the characteristics of
20
21 198 FOG but initial results are promising.
22
23 199
24
25 200 *Gait*. Measurement of gait per se (*micro* characteristics - Figure 1, E-F) is also of interest to the
26
27 201 clinician to evaluate efficacy of clinical management (due to dopa-resistance) as well as for its
28
29 202 potential for use of discrete gait characteristics as diagnostic, prognostic and progression markers ⁴⁶⁻⁴⁸.
30
31 203 Gait assessment during free-living assessment also captures ongoing environmental and cognitive
32
33 204 challenges which impair gait performance. **Assessment** in this context has greater ecological validity
34
35 205 and gives a true picture of the burden of disease ^{3, 7, 49}. Algorithms have been validated to detect
36
37 206 discrete gait characteristics in the laboratory and also in proxy validation studies ⁵⁰⁻⁵⁵. Results showed
38
39 207 good agreement with trusted gold standard reference (e.g. GaitRite or optical motion capture systems)
40
41 208 for the majority of gait characteristics with potential advantages for asymmetry and variability
42
43 209 measures. Apart from Del Din et al. ⁴⁹, the few studies that have examined gait in free living
44
45 210 conditions, quantify few gait characteristics ⁵⁶⁻⁶¹. Discriminative validity has been tested, and has been
46
47 211 shown to discriminate between PD and OA ^{49, 57}, phenotypes of PD ⁶¹ and PD with higher or lower
48
49 212 cognitive functions ⁶⁰. Aside from studies exploring falls and FOG risk highlighted previously ⁵⁷ only
50
51 213 one study has investigated the effect of environment on gait. Free-living gait characteristics showed
52
53 214 better discriminative validity than those collected in the laboratory, especially for medium to long
54
55 215 bouts ⁴⁹. Although initial work is promising, future work is required to confidently realise continuous
56
57 216 monitoring of gait. There are also some fundamental challenges to the field (outlined below).
58
59
60

217

218 *Measures of functional mobility.* Tests of functional mobility such as turning and Timed up and Go
219 (TUG) ⁶²⁻⁶⁴ measure combined movements that invariably incorporate postural transitions. Detection
220 of movements during functional mobility tasks appears accurate ^{62, 63, 65}, and validity (criterion and
221 discriminative) has been established by a limited number of studies ^{62, 65}. Mean turn velocity, slower
222 walking and turning, shorter steps and lower cadence distinguished PD from controls ^{62, 64} and also
223 showed greater sensitivity to dysfunction than clinical rating scales ^{64, 65}. Of interest, free-living
224 assessment appears to discriminate pathology better than testing in the laboratory ⁵⁴ (Figure 1, G).
225 Measurement of functional mobility tasks can therefore be undertaken with a degree of confidence
226 during a standardised test at home, although further work is required to replicate these findings.

227

228 *Ambulatory activity and sedentary behaviour.* One of the earliest applications of WTCD aimed to
229 quantify physical activity (e.g. ambulatory activity) amid rising concerns of the **negative** effects of
230 sedentary behaviour on well-being. This is particularly relevant for people with PD because of the
231 beneficial health benefits activity confers, and its role in mitigating secondary deficit. Ambulatory
232 activity provides a picture of the true burden of disease and therapeutic efficacy ⁶⁶. Proxy measures
233 such as activity logs and diaries are unreliable and lack responsiveness compared with continuous
234 WTCD monitoring ⁶⁷. Physical activity such as intensity of movement (energy expenditure), temporal
235 periods (bouts) of ambulatory activity (e.g. bouts of walking) and sedentary behaviours are quantified,
236 from which *macro* outcomes can be derived ^{66, 68-70} (Figure 1, A-B). The field has advanced further
237 with the application of non-linear approaches to data analysis which in some instances are more
238 sensitive than measures of central tendency (Table 1, Figure 2), such as pattern (alpha (α)) rather than
239 volume of sedentary behaviour showing discriminative properties ⁷¹. Ambulatory activity
240 differentiates disease stage ⁶⁶, and progression ^{72, 73} and shows increased sensitivity to intervention ^{68,}
241 ⁷⁴. Rochester et al. ⁶⁸ demonstrated the advantages of WTCD versus clinical measures when
242 examining the impact of deep brain stimulation (DBS) on ambulatory activity. Whilst standard
243 clinical measure for gait speed (4 meter test), levels of activity (Nottingham extended activities of
244 daily living index (NEADL)) and disease progression (Hoehn and Yahr) failed to show the positive

1
2
3 245 effects of DBS on the outcomes, WTCD-based measures demonstrated significantly improved
4
5 246 patterns of daily activity. Use of WTCD to measure ambulatory activity and sedentary behaviour is
6
7 247 the most advanced of all the fields discussed in this section, and the most widely adopted. Nonetheless
8
9 248 there are still questions over its application, driven by lack of common definitions of ambulatory
10
11 249 activity, validation procedures and structured protocols in controlled settings for validation of
12
13 250 algorithms⁶. These will be considered below.
14

15
16 251

17 252 *Utility and feasibility of WTCD: how acceptable are they?* Most studies do not intentionally test the
18
19 253 feasibility and utility of WTCD but instead draw on secondary data such as informal comments from
20
21 254 patients, reporting adverse events, data loss, or attrition in sensor use over the study period.
22
23 255 Importantly, there are no overwhelmingly negative reports, suggesting that WTCD are broadly
24
25 256 accepted. Although few studies have intentionally tested utility (which we describe as ‘formal testing’
26
27 257 in Table 1), some focused efforts have been made. Utility has been tested for wearable systems
28
29 258 comprising interactive⁷⁵ or multiple sensors^{17, 22, 23, 76}, using both non-standardised and standardised
30
31 259 questionnaires and rating scales²³ (e.g. the post-study usability questionnaire), comfort^{75, 76} (e.g.
32
33 260 comfort rating scale (CRS)) and ‘wearability’/exertion⁷⁶ (e.g. Borg CR-10 Scale, Rapid Entire Body
34
35 261 Assessment (REBA)). Overall the response has been positive, with WTCD generally well tolerated,
36
37 262 comfortable and easy to use. Compliance is high, although in some cases results were influenced by
38
39 263 socio-cultural aspects which may have positively biased results²³.
40

41
42 264

43
44 265 In summary, to date there is no fully validated WTCD system for continuous monitoring of patient
45
46 266 clinical features. Overall, studies are small, there is no consistent reporting of outcome measures,
47
48 267 protocols differ, and devices differ along with device placement. Comparison to a gold standard is
49
50 268 difficult. Knowledge on patient acceptability is limited. A clear process for validation including
51
52 269 replication in external data sets is essential with appropriate reporting according to a standard.
53
54 270 However the WTDC community is aware that this is an important and emerging area of research with
55
56 271 potential for high clinical uptake, and collaborative efforts are underway to redress these issues (see
57
58 272 reviews⁷⁻⁹). Challenges to implementation are due at least in part to broader technological and
59
60

1
2
3 273 practical concerns which are common to all WTCD and influence their state of readiness, irrespective
4
5 274 of application and use. Until these fundamental issues are redressed, robust use of WTCD will be
6
7 275 compromised. The next section highlights some of these broad concerns and discusses approaches to
8
9 276 advance the field.

10
11 277

12 13 278 **Challenges to clinical adoption**

14
15 279 We address 3 key areas fundamental to the use of WTCD that apply to all areas of
16
17 280 measurement: (i) clear definitions of the clinical feature of interest, (ii) validation of real-world data
18
19 281 and WTCD technical challenges, and (iii) consensus on outcomes. We illustrate these using examples
20
21 282 from our own experience in gait and activity and that of others (Figure 3). Finally we summarise
22
23 283 challenges with recommendations for future work and practical suggestions to inform the interested
24
25 284 user (Table 2).

26
27 285

28
29 286 *Defining the clinical feature.* Although on the face of it this seems simple, there are many examples
30
31 287 where unclear definitions have led to inconsistencies in outcomes and confusion when comparing
32
33 288 between studies. A good example relates to ambulatory activity, from which *macro* (e.g. walking
34
35 289 bouts) and *micro* level gait outcomes are derived that underpin many different clinical and research
36
37 290 questions (Figure 1). This stems from a basic definition of what constitutes a walking bout. In some
38
39 291 studies only purposeful bouts of walking are considered (with a cut-off threshold > 60 seconds)
40
41 292 because regular steady state is more likely to be achieved, thus avoiding potential errors in
42
43 293 misclassification from short bouts. However this is problematic because adults perform almost 90% of
44
45 294 walking bouts in less than 60s^{40, 49, 77} resulting in significant data loss and potentially missing the
46
47 295 most relevant data (such as change in variability of walking pattern). Another approach is to include
48
49 296 all bouts of walking⁴⁹ which is arguably more relevant in patient populations. However this is not a
50
51 297 complete solution because disagreement also exists regarding the number of steps required for a bout,
52
53 298 which may vary, ranging from >3 steps to >10 steps. As a consequence comparison across studies is
54
55 299 impossible where difference in step counts range from 2,000 to 10,000 steps^{66, 68, 72, 73}. The situation is
56
57 300 further complicated by the use of 'ghost' (unknown to the end user and hard-wired into WTCD)

1
2
3 301 thresholds **used by the manufacturer** to define consecutive bouts of walking that have a major impact
4
5 302 on *macro* outcomes ⁷⁸ (e.g. total number and pattern of walking bouts) (Figure 3, (1)). This uneven
6
7 303 approach significantly impacts on both *macro* and *micro* outcomes and therefore consensus as to a
8
9 304 clear definition of walking is urgently required ^{6, 78}. Attempts are underway to improve definitions
10
11 305 which will greatly help (Chastin et al.: ALPHABET: Development of A Physical Behaviour
12
13 306 Taxonomy with an international open consensus¹).

14
15 307

16
17 308 *Algorithm development, validation and technical challenges: Influence of context and protocol.*

18
19 309 Establishing a gold standard to test algorithm validity for the range of features highlighted in this
20
21 310 review during continuous uncontrolled monitoring in a free-living environment is a major challenge
22
23 311 without obvious solutions. Real-life is unpredictable and unstructured. For example, context
24
25 312 (environment and task) affects walking speed and direction which has implications for accuracy of
26
27 313 algorithms used to detect steps and phases of the gait cycle from which gait characteristics are
28
29 314 determined (Figure 3). Studies often adopt a number of different testing protocols and various sensor
30
31 315 configurations (type and location (upper or lower body, Table 1) which also impacts the signal
32
33 316 waveform influencing the accuracy of the algorithm used to extract micro outcomes and other type of
34
35 317 information (features, outcomes). Moreover algorithms are usually validated using healthy controls
36
37 318 data and adopted for analysing other groups' data (i.e. PD) without considering that speed (fast or
38
39 319 slow), pathology itself and disease stage may impact on the raw signal (Figure 3, (2)) and therefore
40
41 320 influence algorithm performance. In addition other technical considerations need to be taken into
42
43 321 account. Many commercial devices adopt black box designs with un-validated firmware/software ⁷⁹
44
45 322 which account for at least some of the significant disagreements in reported results ^{80, 81}. Other
46
47 323 uncertainties due to externally induced motion (e.g. cars, lifts) also impact on accuracy to detect
48
49 324 features of interest ⁸¹. Static and dynamic re-calibration of WTCD to account for possible axis
50
51 325 misalignment or sensor alterations due to damage (device dropped, contact with water etc.) is also
52
53 326 advised ⁸², however rarely undertaken because procedures are complicated and expensive. Further
54
55 327 sources of variability are also introduced through changes in external factors such as weather, mood

56
57
58 ¹ <https://osf.io/2wuv9/>

1
2
3 328 or medication, influencing analysis of the signal. Collectively these result in errors and decreased
4
5 329 confidence in outcomes and conformity to everyday use. Algorithm development will ultimately
6
7 330 refine extraction and a joint approach such as use of secondary data sources will aid interpretation, for
8
9 331 example data from patients' diaries, testimony from carers, and use of clinical records⁸³. All of these
10
11 332 potential sources of error should be considered and some suggestions are provided in Table 2.

12
13 333
14
15 334 *Determining optimal outcome measures.* Table 1 shows the vast range of outcomes reported.
16
17 335 Standardised measurement is urgently needed with a clear rationale for selection of outcomes from
18
19 336 which clinimetric testing will allow a refined battery of measures to emerge to encourage
20
21 337 harmonisation across studies. Examples of measurement frameworks have been described^{46, 49}
22
23 338 including our own *micro* and *macro* level structure used throughout this paper⁴⁷. Others^{37, 38, 45, 57, 61}
24
25 339 beside volume outcomes (e.g. total number of walking bouts, etc.) defined as '*quantity*' metrics, use
26
27 340 novel frequency-based outcomes to characterise gait (a) symmetry, variability and stability (e.g.
28
29 341 harmonic ratio, amplitude of dominant frequency, dynamic stability, etc.) defined broadly as '*quality*'
30
31 342 metrics. These novel *quality* measures, although very promising for discriminative validity, may be
32
33 343 difficult to interpret in clinical practice.

34
35 344

36
37 345 <Figure 2>

38
39 346 <Figure 3>

40
41 347

42 43 348 **Free-living monitoring in PD: where to next?**

44
45 349 Modern devices incorporate a range of inertial sensors such as accelerometers, gyroscopes,
46
47 350 magnetometers with Bluetooth connectivity which constitute cutting edge WTCD. While use is
48
49 351 currently limited to controlled settings, improvements in battery technology will improve the accuracy
50
51 352 of measurement addressing some of the challenges highlighted earlier. Moreover, novel methods for
52
53 353 advanced data processing are being developed to reduce computational load with advanced
54
55 354 computational processing carried out remotely via smartphone or in the cloud extending the
56
57 355 application of WTCD⁸⁴. Studies have also investigated the use of smart phones (and audio devices)

1
2
3 356 which regularly come with the necessary hardware to quantify symptoms, movement or gait⁸⁵. These
4
5 357 devices capture, analyse and relay information via cellular or other wireless networks and also provide
6
7 358 a more comprehensive assessment such as the addition of a microphone for use with speech analysis
8
9 359 algorithms in PD diagnosis^{86, 87} and visual displays to facilitate applications (apps) for the study of
10
11 360 cognition⁸⁸. Rigorous device testing however is needed to ensure confidence in their application.

12
13 361 Long term monitoring via a smart phone facilitates network interconnectivity and integration
14
15 362 to the Internet of Things (IoT)⁵, through delayed or real-time uploading of data to cloud computing
16
17 363 infrastructures. Data can be relayed to the patient (bio-feedback) via unobtrusive displays, haptic and
18
19 364 audible cues. Data is stored and sent to clinicians for tracking disease progression, optimising disease
20
21 365 management and providing further, more clinically informed feedback to the patient. Data storage and
22
23 366 data access on this scale constitutes 'big data analytics'. Developments in this field can expand
24
25 367 assessment to capture the 'lived experience' or 'livespace' of PD, capturing the extent to which people
26
27 368 travel and their patterns of movement within the community⁸⁹. This is exemplified by a recent
28
29 369 collaborative project between the Michael J. Fox Foundation and Apple utilising their projects,
30
31 370 FoxInsight² and the Apple ResearchKit³ (inc. the Parkinson mPower app⁴ available via iTunes),
32
33 371 respectively.

34
35 372 Collection of data on the scale and in a free-living context raises new ethical challenges with
36
37 373 respect to acquisition, analysis and storage. Current ethical reviews may not be sufficient to identify
38
39 374 modern issues⁹⁰. Technology and terminology has evolved faster than legal and ethical systems and
40
41 375 unforeseen issues can emerge⁹¹. Informed, principled, and collaborative experimentation are therefore
42
43 376 necessary to ensure privacy and confidentiality, and compliance with ethical principles.

44
45
46 377

47 378 **Conclusions and recommendations**

48
49 379 There is no doubting the possibilities and potential of real world monitoring and assessment
50
51 380 of clinical features for people with PD. It is conceivable to imagine a future where *micro* level data is
52
53 381 used to enhance diagnostics, measure efficacy of intervention and monitor disease progression, and

58 ⁴ <http://parkinsonmpower.org/>

1
2
3 382 predict risk of disease, falls and cognitive decline. *Macro* level data, on the other hand, reflects the
4
5 383 global burden of disease and impact of therapy. Both sources of data provide insights into
6
7 384 personalised treatment. As this special issue in the journal indicates, this is a rapidly developing field.
8
9 385 However, much work remains before widespread clinical adoption is a reality. We highlight key
10
11 386 recommendations and some practical solutions to move this field forward (Table 2). These challenges
12
13 387 are likely to be met most effectively by adopting a multidisciplinary approach between key
14
15 388 stakeholders such as clinicians, patients, engineers, computer scientists, and statisticians.

Tables

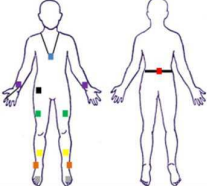

Table 1: Studies examining free-living monitoring of Parkinson’s disease (PD) using wearable technology and connected devices (WTCD).

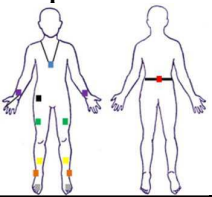

Number and position of WTCD used in each study is detailed in column two using a colour code (blue = chest, violet = wrist, black = pocket, green = thigh, yellow = shank, orange = ankle, grey = foot, red = lower back).

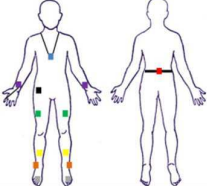

† Clinical feature/ activity detected or measures has been classified using three types of validity: 1) accurate detection of clinical feature/ method of appraisal: the ability of WCTD algorithms to accurately detect a clinical feature/activity which is comparable to detection by another means - in the study cited or previous studies (e.g. self-report, EMG); 2) criterion validity: the association between WTCD-derived outcomes and measures such as clinical scales; and 3) discriminative validity: the ability of WTCD-derived outcomes to discriminative between groups. Formal testing of utility (feasibility/compliance intentionally tested and reported) of WTCD is also reported.

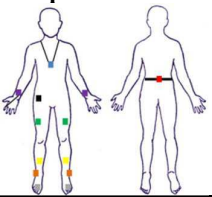

Study (Year), N, Length of recording	WTCD and placement	Clinical feature/ Activity	Accurate detection of clinical feature: Method of appraisal†	Measures	Criterion Validity†	Discriminative Validity†	Utility
<i>Motor symptoms and medication response</i>							
Das et al. (2012), 2 PD, 4*	Accelerometers --- 	Dyskinesia, tremor	Yes, against patients’ diaries using weakly supervised machine learning technique.	Acceleration derived features (Mean energy, high frequency energy content, correlation, frequency domain entropy)	No	No	No
Griffiths et al. (2012), 34 PD/10 OA, 10	Parkinson's KinetiGraph (PKG; Global Kinetics Corporation) 	Bradykinesia, dyskinesia	Yes, for bradykinesia against dot slide task measure (specificity 88%, sensitivity 95%) during scripted tests.	Acceleration derived features: Mean Spectral Power within specific bands, peak, amount of time with no movement	Yes, dyskinesia against the AIMS score and both dyskinesia and bradykinesia against UPDRS III and IV	No	No
Mera et al. (2012), 10 PD/ 10 OA, 3-6	Kinesia™ 	Motor tasks, tremor, bradykinesia, motor fluctuations	No	Symptoms severity scale (0-4 points), voluntary movement threshold evaluated with gyroscope derived features (RMS, peak of power spectrum)	Yes, for tremor and bradykinesia. Potential issues of recognition when the 2 symptoms overlap. Yes against videos in the lab for symptom severity scale validated against UPDRS tremor and MBRS speed, amplitude and rhythm scores in previous work ^{75, 92}	No	Yes, formal testing previous work ⁷⁵
Pastorino et al. (2013), 2 PD, 7	ALA-6g (PERFORM) 	Akinesia, ON/OFF state	Yes, ‘proof of concept’ validation	Level of akinesia	No	No	Yes, formal testing

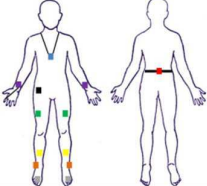

Study (Year), N, Length of recording	WTCD and placement 	Clinical feature/ Activity	Accurate detection of clinical feature: Method of appraisal†	Measures	Criterion Validity†	Discriminative Validity†	Utility
(but 32 hours analysed)			against patients' diaries				
Tzallas et al. (2014), 12 PD, 5 (8 hours per day)	ALA-6g (PERFORM) 	Tremor, LID, Bradykinesia, FOG	Yes, in the lab and during structured test (e.g. for FOG events Opening door/ Straight 10m walking) against video annotations.	Acceleration derived measures (time and frequency domains, RMS, range, entropy, energy)	Yes, machine learning and leave one out validation technique validated in the lab and applied in free- living conditions and compared against patients' diaries. Use of videos in the lab for assessing symptoms severity using UPDRS.	No	Yes, formal testing
Ferreira et al. (2015), 11 PD, 12 weeks	SENSE-PARK System 	Gait, hypokinesia, dyskinesia, tremor, sleep	No/NA (feasibility study and usability)	NA	NA	No	Yes, formal testing
Hammerla et al. (2015), 34 PD, 7	Axivity AX3 	Sleeping, ON/OFF state, dyskinesia	Yes, in the lab (against video recordings) using machine learning and leave one out validation technique, in free-living conditions results are compared against patients' diaries. Model pre-trained in free-living conditions did not give good results (laboratory data is a poor model for naturalistic behaviours)	Acceleration derived measures (magnitude, jerk, power spectral density, etc.)	No	No	Yes, formal testing but in subsequent work ⁹³
Horne et al. (2015), 64 PD/38 OA, 10	Parkinson's KinetiGraph (PKG; Global Kinetics Corporation) 	Bradykinesia, dyskinesia, fluctuations	Yes, against measures of bradykinesia and dyskinesia (previous work see Griffiths 2012)	Fluctuation Score based on Interquartile Range of bradykinesia and dyskinesia scores.	Yes, against clinical scores derived measure	Yes	No

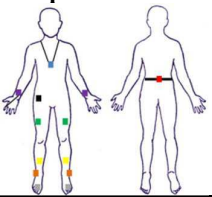

Study (Year), N, Length of recording	WTCD and placement 	Clinical feature/ Activity	Accurate detection of clinical feature: Method of appraisal†	Measures	Criterion Validity†	Discriminative Validity†	Utility
<i>Sleep</i>							
Prudon et al. (2013), 106 PD/99 OA, 3 nights	Acti-watch, Camntech 	Leg movements during sleep	Yes, in patients with periodic leg movement (against electromyography), previous work	Periodic leg movements index	Yes, against disease severity	No	No
Louter et al. (2015), 11 PD, 2 nights	Dynaport McRoberts 	Turning during sleep	Yes, against polysomnography in adults with obstructive sleep apnoea syndrome, previous work ⁹⁴	Acceleration derived measures (e.g. mean) and axial movement measures (frequency, size, duration, speed)	Yes, against Acti-watch but in young healthy adults previous work ⁹⁴	Yes	Yes, no formal testing, previous work
Sringean et al. (2015), 19 PD, 1 night	NIGHT-Recorder system 	Turning, Standing	No, video and sleep diaries collected but validity not formally tested.	Acceleration and gyroscope derived measures (duration of sleep, axial movements, velocity, etc.)	Yes, against clinical scores (UPDRS axial score, item #28, etc.)	Yes	Yes, no formal testing, no adverse events reported
<i>Falls and Falls Risk</i>							
Weiss et al. (2013), 71 OA, 3	Dynaport McRoberts 	Walking (at least 60s)	No	Number of walking bouts, walking duration, total number of steps, median number of steps per bout, bout duration, cadence, step and stride regularity, frequency domain measures (harmonic ratio, amplitude, slope and width of dominant frequency), step duration, step symmetry, acceleration range, etc.	Yes, against clinical scores of fall risk and laboratory based measures	Yes	No
Weiss et al. (2014), 107 PD, 3	Dynaport McRoberts 	Walking (at least 60s)	No	Number of walking bouts, % of activity duration, total number of steps, median number of steps per bout, bout duration, cadence, stride regularity, frequency domain measures (harmonic ratio,	Yes, against clinical scores of fall risk	Yes	Yes, no formal testing, data loss reported.

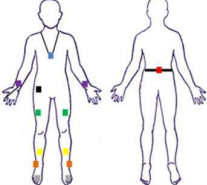

Study (Year), N, Length of recording	<p>WTCD and placement</p> 	Clinical feature/ Activity	Accurate detection of clinical feature: Method of appraisal†	Measures	Criterion Validity†	Discriminative Validity†	Utility
Brodie et al. (2015), 18 EF, 58 (average)	Senior Mobility Monitor (SMM, Philips) --■--	Walking (at least 3 or 8 steps)	No	amplitude and width of dominant frequency), etc. Steps per day, walking bouts per day, steps per bout, cadence, distribution of bout length	No	Yes	No
Hiorth et al. (2015), 48 PD, 7	activPAL ■	Sedentary behaviour/ standing/ walking	Yes, but not formal in PD. Previous work in OA against other accelerometer ⁹⁵ and video recordings in people with rheumatoid arthritis during simulation of ADL in the laboratory ⁹⁶	Volume (e.g. total number of sedentary/standing/walking bouts), pattern (α), variability of sedentary bouts and number of strides per walking bout.	Yes, against clinical scores	Yes	No
Mactier et al. (2015), 111 PD, 7	activPAL ■	Walking	Yes, but not formal in PD. Previous work in OA against other accelerometer ⁹⁵ and video recordings in people with rheumatoid arthritis during simulation of ADL in the laboratory ⁹⁶	Volume (e.g. total number of walking bouts), pattern (α), variability of bouts, accumulation of stepping bouts	No	Yes	No
Rispen et al. (2015), 113 OA, 14	Dynaport McRoberts ■	Walking (at least 10s)	Yes, previous work in OA ⁹⁷ for walking volume parameters against videos, no for gait characteristics.	Acceleration based outcomes: gait speed, speed variability, stride time, stride regularity, stride time variability, stride frequency, frequency domain measures (harmonic ratio, amplitude, slope and width of dominant frequency), etc.	Yes, measures against self- reported fall history	No	No
van Schooten et al. (2015), 169 OA, 8	Dynaport McRoberts ■	Walking (at least 10s), sitting, lying, and standing	Yes, previous work in OA ⁹⁷ for walking volume parameters against videos, no for	Total duration of walking, sitting, standing, and lying per day, number of	Yes, against falls history	Yes	No

Study (Year), N, Length of recording	WTCD and placement 	Clinical feature/ Activity	Accurate detection of clinical feature: Method of appraisal†	Measures	Criterion Validity†	Discriminative Validity†	Utility
			gait characteristics.	strides, number of walking bouts, duration of bouts, number of transitions. Gait characteristics: gait speed, stride frequency, stride length frequency domain measures (harmonic ratio, power at dominant frequency), etc.			
Kangas et al. (2015), 16 OA, 5-155	CareTech Ab 	Falls‡	Yes, fall event against care personnel's reports and in previous work in OA during simulation of fall events in controlled conditions ⁹⁸ in OA	Fall event with alarm generation	No	No	Yes, based on alarm accuracy
<i>Freezing of Gait (FOG)</i>							
Moore et al. (2013), 25 PD, NA	Xsens MTx 	Turning/ walking (TUG)‡	Yes, in the laboratory for FOG event against video recordings	FOG event through acceleration derived frequency measures (power spectrum, etc.).	No	No	No
Tripoliti et al. (2013), 11 PD/5 OA, NA	Body Sensor AGYRO, AGYRO links, ANCO S.A. 	Walking, FOG detection‡	Yes, against video recordings and visual inspection during structured test (Opening door/ Straight 10m walking) using different classification algorithms and cross-validations	FOG detection through entropy of WTCD signal	No	No	No
Weiss et al. (2015), 72 PD, 3	Dynaport McRoberts 	Walking (at least 60s)	No	Number of walking bouts, % of activity duration, total number of steps, median number of steps per bout, bout duration, cadence, stride regularity, frequency domain	Yes, against clinical scores (FOG questionnaire)	Yes	No

Study (Year), N, Length of recording	WTCD and placement 	Clinical feature/ Activity	Accurate detection of clinical feature: Method of appraisal†	Measures	Criterion Validity†	Discriminative Validity†	Utility
				measures (harmonic ratio, width of dominant frequency), etc.			
<i>Gait</i>							
Cancela et al. (2011), 10 PD, 1 (not clear)	ALA-6g (PERFORM) 	Walking (on vs off medication)	Yes, only for step frequency during 10m scripted protocol against visual examination	Step frequency, stride length and speed, entropy, arm swing	No	Yes, only for entropy in previous work ⁹⁹	No
Weiss et al. (2011), 22 PD/17 OA (1PD/1CL at home), 3	Mobi8 	Walking (during scripted test in the lab and during simulation of ADL and free- living)	No	Acceleration derived measures (time and frequency domains): stride time, stride time variability, amplitude, width, slope of dominant frequency, etc.	Yes, against clinical scores	Yes	No
Cancela et al. (2014), 11 PD, 5-7 (8 hours per day)	ALA-6g (PERFORM) 	Walking	Yes, only for step frequency, previous work (see Cancela 2011)	Step frequency, step velocity, stride length, entropy	No	Yes, only for entropy in previous work ⁹⁹	Yes, formal testing and also assessed in separate study ⁷⁶
Herman et al. (2014), 110 PD, 3	Dynaport McRoberts 	Walking (at least 60s)	No	Total number of activity bouts, total % of activity duration, total number of steps, mean activity bout duration, median number of steps per bout, cadence, stride regularity, amplitude of dominant frequency, width of dominant frequency, stride regularity, harmonic ratio, Phase Coordination Index.	Yes, previous work	Yes, previous work	No.
Weiss et al. (2015), 107 PD, 3	Dynaport McRoberts 	Walking (at least 60s)	No	Total % of activity duration, total number of steps, cadence, amplitude of dominant frequency, stride regularity, harmonic ratio,	Yes, previous work	Yes, previous work	Yes, no formal testing, data loss reported

Study (Year), N, Length of recording	WTCD and placement 	Clinical feature/ Activity	Accurate detection of clinical feature: Method of appraisal†	Measures	Criterion Validity†	Discriminative Validity†	Utility
				<i>Phase Coordination Index.</i>			
Del Din et al. (2016), 47 PD/50 OA, 7	Axivity AX3 	Walking (at least 3 steps)	No	14 gait characteristics: mean step time, stance time, swing time, step length, step velocity, step time variability, stance time variability, swing time variability, step length variability, step velocity variability, step time asymmetry, stance time asymmetry, swing time asymmetry, step length asymmetry.	Yes, gait characteristics validated against laboratory reference (previous work ⁵³)	Yes	No
				<i>Timed-up-and-go (TUG)</i>			
Zampieri et al. (2011), 6 PD/8 OA, 1	Physilog 	Walking/turni ng/postural transitions †	Yes, in previous work ¹⁰⁰	Cadence, stride velocity, stride length, peak arm velocity, turning velocity	No	Yes	No
Smith et al. (2016), 12 OA, 5	SHIMMER 	Walking/turni ng †	No	Time to complete test, cadence, gait characteristics (step time, stride time, stride length, stride velocity, etc.), turning magnitude, etc.	No	No	No
				<i>Turning</i>			
El-Gohary et al. (2013), 12 PD/18 OA, 7*	Opal(ADPM)  in the lab / Opal(ADPM)   at home	Turning/ walking (at least 10s)	Yes, in the lab against motion analysis system and video recordings	Number of turns, peak velocity, mean velocity, duration of turn	No	Yes	No
Mancini et al. (2015), 13 PD/8 OA, 7*	Opal(ADPM)   	Turning/ walking (at least 10s)	Yes, in the lab (previous work, see El-Gohary 2013)	Number of turns/hour, turn angle, turn duration, number of steps/turn, turn mean velocity and coefficient of variation of these measures.	Yes	Yes	Yes, no formal testing, report of 'ease' of use.
				<i>Ambulatory activity and sedentary behaviour</i>			
Chastin et al. (2007), 17 PD/17 OA, 7	activPAL 	Sedentary behaviour	Yes, but not formal in PD. Previous work in OA against other	Volume of sedentary bouts, pattern (α), pattern of accumulation of bouts (GINI)	No	Yes	No

Study (Year), N, Length of recording	WTCD and placement 	Clinical feature/ Activity	Accurate detection of clinical feature: Method of appraisal†	Measures	Criterion Validity†	Discriminative Validity†	Utility
			accelerometer ⁹⁵ and video recordings in people with rheumatoid arthritis during simulation of ADL in the laboratory ⁹⁶	index)			
Dontje et al. (2013), 467 PD, 14	TracmorD, Philips/ --■-- or --■-- or ■	Physical Activity/Sedentary behaviour	Yes, against doubly labeled water technique (correlation) in adults but not in PD ¹⁰¹	Energy expenditure, time spent in activities, distribution of activities, etc.	Yes	No	No
Benka Wallen et al. (2015), 95 PD, 7	ActiGraph GT3X+ -- ■	Physical Activity/Sedentary behaviour/Steps (60s epochs)	Yes, in young adults under controlled conditions by visual observation but not in PD ¹⁰²	Volume (magnitude vector of acceleration) and time spent in physical activities, steps per day, etc.	No	No	No
Lim et al. (2010), 153 PD, 1	Vitaport3, TEMEC Instruments BV ■■■	Sitting, standing, walking	Yes in PD against video (under controlled conditions), previous work ¹⁰³	% of time spent on dynamic, static, sitting, standing or walking activities, number of walking bouts > 5s and > 10s	No	No	No
Cavanaugh et al. (2012), 33 PD, 7	StepWatch 3 Step Activity Monitor (SAM) ■	Walking (average every 60s)	Yes, for stride count in PD against instrumented walkway in the lab, previous work ¹⁰⁴	Total number of steps, maximum output for steps, number of minutes with > 100 steps, number and duration of walking bouts, peak activity index, % of day spent inactive	No	No	Yes, not formal testing, reasons for data loss and attrition in sensor acceptability after 1 year with decrease in participant use reported
Rochester et al. (2012), 17 PD, 7	activPAL ■	Walking	Yes, but not formal in PD. Previous work in OA against other accelerometer ⁹⁵ and video recordings in	Volume of walking bouts, pattern of accumulation of bouts (GINI index) and diversity of bouts, distribution and variability of bouts (S ₂)	Yes	No	No

Study (Year), N, Length of recording	WTCD and placement 	Clinical feature/ Activity	Accurate detection of clinical feature: Method of appraisal†	Measures	Criterion Validity†	Discriminative Validity†	Utility
Lord et al. (2013), 89 PD/97 OA, 7	activPAL 	Walking	people with rheumatoid arthritis during simulation of ADL in the laboratory ⁹⁶ Yes, but not formal in PD. Previous work in OA against other accelerometer ⁹⁵ and video recordings in people with rheumatoid arthritis during simulation of ADL in the laboratory ⁹⁶	Volume of walking bouts, pattern (α), time spent walking in short-medium or long bouts, frequency and variability of bouts (S_2)	Yes	Yes	No
Cavanaugh et al. (2015), 17 PD, 7	StepWatch 3 Step Activity Monitor (SAM) 	Walking (average every 60s)	Yes, for stride count in PD against instrumented walkway in the lab, previous work (see Cavanaugh 2012)	Mean daily steps, maximum output for steps, Moderate intensity minutes (number of minutes with > 100 steps)	Yes	No	Yes, not formal testing, reasons for data loss and attrition in sensor acceptability after 2 years with decrease in participant use reported

ADL = Activities of Daily Living; Alpha = α ; Lab = Laboratory; Length of recording= number of weeks/days/minutes of recording; MBRS = Modified Bradykinesia Rating Scale; min = minutes; N = number of participants; OA = Older Adults; PD = Parkinson's disease; RMS = Root Mean Square; UPDRS = Unified Parkinson's Disease Rating Scale; % = Percentage; *Night excluded; † = scripted protocol/supervised conditions used.

Table 2: Practical solutions and broad recommendations for WTCD-related research challenges.

Recommendation	Practical solutions
Adopt standardised definition of activity/clinical feature	<ul style="list-style-type: none"> Justify definition of activity/clinical feature with respect to earlier work & clinical expertise. Adopt interdisciplinary collaboration for optimal process, choice of equipment, protocol, data processing and outcomes adhering to research question(s).
Select equipment depending on research/clinical question; evaluate trade-off between information needed & equipment available.	<ul style="list-style-type: none"> Consider optimal technical specifications (e.g. sampling frequency, type of data collected; battery life) for outcome measures. Use WTCD with established utility, acceptability and cost-effectiveness, otherwise plan to include tests of utility and acceptability as part of the study. Ensure transparency of all aspects of technology used (specifications, data collection, data pre-processing).
Use standardised protocols & validation procedures for algorithms for comparability & reproducibility across studies (e.g. accurate detection of activity/clinical feature, criterion & discriminative validity).	<ul style="list-style-type: none"> Justify use of standardised protocol & methods to define activities/clinical features. Use algorithms previously validated for the current application or provide validation results for novel algorithms. Use appropriate gold standards (e.g. video recording) to validate outcomes/metrics in free-living conditions, not limiting validation to scripted protocols or controlled conditions. Account for influence of context and disease severity on algorithm performance. If proprietary software is used ensure transparency of manufacturer algorithms or report published validated algorithm.
Achieve consensus for summary outcomes for comparability across studies.	<ul style="list-style-type: none"> Use WTCD-based outcomes validated in free-living; or provide validation results in the current study using semi-structured activities. Describe (if any) dependence of chosen summary outcomes & on chosen data processing/algorithm.

Figures

Figure 1:

Use of wearable technology and connected devices (WTCD) (adapted with permission from previous work)⁴⁷ A) *macro* level quantification of activities over an extended period of time (volume, patterns and variability); (B) bouts of activities (e.g. lying (sleeping), walking, sitting); (C-H) *micro* level quantification from specific events: C) and D) postural transitions, E) shuffling, F) gait, G) turning, H) freezing of gait (FOG) and fall.

Figure 2:

Examples of linear and non-linear approaches to activity data analysis: volume and pattern metrics for two subjects (Subject 1 and 2) (published with permission)⁶⁸.

A1 and A2 - Patterns of activity indicating bouts of sedentary, standing and walking at different stepping rates (cadences).

B1 and B2 - Volume Metrics: total walking time for the two subjects is equal but made up of walking bouts at different cadences.

C - Pattern Metrics: (i) and (ii) distribution of walking bouts for these two subjects with equal mean (M) and different dispersion (S2). C (iii) Accumulation pattern of walking time for subject 1 and 2; subject 2 tends to accumulate walking time with predominantly longer periods.

Figure 3:

Challenges/limitations of free-living measurement using examples from gait in free-living collected with a single accelerometer-based WTCD. Data (unpublished) from the Incidence of Cognitive Impairment in Cohorts with Longitudinal Evaluation-GAIT (ICICLE-GAIT) study¹⁰⁵.

Panel (1) – Definition of feature of interest (e.g. walking):

A) Impact of “selected” definition of walking on data processing: different threshold of walking bout length and (ghost) maximum resting period (MRP) between consecutive walking bouts can be utilised.

Examples: (i): use of walking bout threshold of 60s and no MRP (MRP = 0s) (only bouts longer than 60 s will be considered); (ii): use of walking bout threshold of 3 steps and no MRP (MRP = 0s); (iii) use of walking bout threshold of 3 steps and MRP = 5s.

B) Impact of choice in A) on *macro* outcomes (e.g. number of bouts considered, total number of steps reported for people with Parkinson’s disease (PD) and controls (CL)). For example using definition (i) only a small percentage of all the walking bouts will be considered (bouts > 60s only) and therefore fewer steps will be reported if compared to results of using definition (ii).

C) Impact of choice in A) on *micro* gait characteristics (e.g. reported step velocity may vary across studies due to choice of definition ((i), (ii) or (iii)).

Panel (2) – Influence of free-living protocol on data:

Walking speed changes with respect to the environment, task, and disease severity which influences the accelerometer raw signal (D) impacting on algorithm performance and evaluation of outcomes (E).
