Abstract

A Rh-catalyzed ortho-amidation of 2-aryloxazolines offers an efficient and direct route to a range of sulfonamides. The scope of the reaction is very broad with respect to sulfonamide substrate, but the position and electronic nature of the substituents on the aryl moiety of the oxazoline lead to a surprising modulation of reactivity. The reactivity of sulfonamides in comparison to trifluoroacetamide is compared, the latter undergoing Rh-catalyzed amidation more rapidly.
Introduction

Sulfonamides represent an important functional group within organic chemistry as evidenced by their prevalence within natural and non-natural compounds.\(^1\) Typical synthetic approaches rely on the functionalization of anilines or amines with reactive sulfonyl chlorides (scheme 1a).\(^2\) Buchwald-Hartwig cross-coupling represents a powerful and complementary C-N bond forming alternative (scheme 1b). However, the methodology requires the use of a pre-functionalized coupling partner in the form of a halide/pseudo halide.\(^3\) An alternative means of introducing of the sulfonamide group is by C-H activation (scheme 1c). C-H activation has emerged as a very successful approach towards the synthesis of complex molecular scaffolds.\(^4\) In particular, C-H amidation protocols represent a powerful strategy for the formation of C(sp\(^2\))-N bonds, in which sulfonamides have been demonstrated to be successful coupling partners.\(^5\)

Scheme 1: N-Arylsulfonamide synthetic methods

We recently disclosed an efficient and regioselective rhodium-catalyzed C-H amidation/cyclization sequence to afford functionalized quinazoline and quinazolinone derivatives.\(^6\) We also recently described the successful applicability of our methodology on
2-substituted pyridines. Within our rhodium-catalyzed C-H amidation step, we chose the trifluoroacetamide as the amino source because of the ease of hydrolysis of this functionality. However, we recognized the potential of this strategy to directly deliver a range of N-aryl sulfonamides and report herein the scope of this process. Moreover, we highlight some surprising reactivity differences with regard to the substrate amine donors and aryl acceptors.

Our investigations were inspired by Su and co-workers who demonstrated the successful Rh-catalyzed reaction of 2-phenyl pyridines with an array of functionalized sulfonamides. In addition, a small selection of aryl oxazolines were disclosed (4 examples) that were employed in conjunction with para-toluenesulfonamide. Given the potential for oxazolines to be used as surrogates for carboxylic acid derivatives, we decided to fully investigate the scope of the oxazoline directed rhodium-catalyzed C-H amidation of aromatic compounds with aryl sulfonamides.

**Results and Discussion**

Our previous work had highlighted that oxazolines promote an unusually mild amidation reaction when trifluoroacetamide is employed; the product yields are similar when the reactions are conducted at 100 °C or 40 °C. Furthermore, the reaction was found to proceed quite efficiently at room temperature. We decided to carry out a similar investigation using para-toluenesulfonamide, in order to identify an optimal reaction temperature and to compare the reactivity of this amine source with trifluoroacetamide. As depicted in scheme 2, the reaction was found to proceed well at 100 °C affording the C-H amidated product in an excellent yield of 92%. In contrast to trifluoroacetamide however, lowering the temperature to 40 °C led to a significant drop in yield. Moreover, conducting the reaction at 25 °C resulted in a poor isolated yield of 22% – highlighting the sluggish nature of this substrate at ambient temperature. Overall, we were interested to note that the reaction conditions required
to afford efficient C-(sp$^3$)N bond formation were harsher in the case of the sulfonamide versus trifluoroacetamide, implicating a key role of the amine donor’s role in dictating reactivity.

**Scheme 2: Comparative study of reaction temperature on the reactivity of trifluoroacetamide and para-toluenesulfonamide**

We next decided to investigate the nature of sulfonamides which could be used in conjunction with aryl oxazolines in the rhodium-promoted system (scheme 3). Pleasingly, a range of aromatic sulfonamides could be used alongside the gem-dimethyl oxazoline directing group at the optimum reaction temperature of 100 °C and only mono-aminated products were observed in all cases. Under the standard reaction conditions both electron withdrawing and electron donating functionalities were well tolerated by the sulfonamide group. Additionally, ortho-, meta- and para-methyl functionalized sulfonamides afforded the C-H amidated products in good to excellent yield. Finally, alkyl sulfonamides were found to
be viable substrates in combination with both the unsubstituted and gem-dimethyl oxazoline
directing group.

**Scheme 3: Sulfonamide scope**

We then turned our attention to the functionalities on the aryl oxazoline (scheme 4).
Pleasingly under the optimum reaction conditions, we found a small selection of
electronically distinct aryl oxazolines were well tolerated. Both electron poor and electron
rich aryl systems were successful, as demonstrated by the methoxy- and trifluoromethyl-
substituted examples (12 and 13).

**Scheme 4: Oxazoline scope**
In an effort to demonstrate utility of this particular transformation we targeted the synthesis of sulfonamide 16, a known potassium ion channel inhibitor. We envisaged that the employment of our optimal C-H amidation conditions for sulfonamides would readily deliver 16 from 3-methoxy substituted aryl oxazoline 15 and 3-(trifluoromethyl)benzenesulfonamide (scheme 5). In the event, we were surprised to find that this reaction failed to proceed, even after heating over an extended time period. In order to rule out the sulfonamide as the source of low reactivity, 3-(trifluoromethyl)benzenesulfonamide was reacted with 2-phenyl oxazoline 17. This reaction proceeded smoothly to afford the corresponding product 18 in an excellent yield of 83%. We next decided to further examine the reactivity of 3-methoxy substituted aryl oxazoline 15 by subjecting it to our standard reaction conditions with trifluoroacetamide. Interestingly, in this case we observed only a poor yield of 20% of product 19. Finally, 4-methoxyphenyl oxazoline 20 was found to show good reactivity towards 3-(trifluoromethyl)benzenesulfonamide, affording compound 21 in 62% yield. Taken together, these results indicated that the C-H amidation reaction could be retarded by the presence of an electron donating substituent situated meta to the oxazoline directing group.

Scheme 5: Initial investigations into the effect of electron donating groups on oxazoline reactivity
In order to explore the generality of this observation, an array of para- and meta-substituted aryl oxazolines bearing both electron donating and electron withdrawing functionalities were prepared. For the purpose of comparison, each substrate was subjected to the optimum reaction conditions with para-toluenesulfonamide at 100 °C and trifluoroacetamide at 40 °C. As shown in scheme 6 and in a similar manner to above, the incorporation of an electron donating methoxy group para- to the oxazoline was highly successful with both amino sources delivering the corresponding products in high yield. In contrast, when the methoxy group was meta- to the directing group the reaction was significantly retarded. These data clearly show that the positioning of the functional group can have a profound effect on
reactivity. Next, the reactivity of methyl substituted oxazolines was investigated. We observed better overall reactivity in these cases, however, the combination of a meta-methyl group and the less reactive sulfonamide resulted in product 29 being generated in rather modest yield. Switching to an electron withdrawing ester substituent, we were interested to note that both para- and meta-functionalized examples afforded similar reaction outcomes. Both substrates were reactive and the desired compounds were isolated in good yields. Finally, we wanted to explore the effect of a fluorine group on the C-H amidation reaction. In this series, the para-functionalized example produced the C-H amidated products with both amino sources in good to excellent yield. However, in the case of the meta-functionalized example, we observed insertion at the more hindered position between the oxazoline and the fluoride. This regioselectivity was surprising as we had not observed the analogous regiochemical C-H insertion in any of our other meta-substituted examples. The outcome was independent of amine source and both para-toluenesulfonamide and trifluoroacetamide inserted into the 2-position of the aryl ring with high selectivity and yield. The structure of the C-H amination product arising from the reaction between 3-fluro substituted oxazoline and para-toluenesulfonamide was unambiguously confirmed by X-ray crystallography. Notably, selective insertion into the 2-position of similar meta-fluoro scaffolds by C-H activation methodologies has received only scant precedent. Reports by Sanford and others demonstrated insertion into the 6-position under palladium-catalyzed C-H activation. A single report by Yu described a mixture of insertion products (1:1.5 C₂:C₆) when N-(2-(4,5-dihydrooxazol-2-yl)phenyl)-2-fluorobenzamide is subjected to C-H amidation conditions with stoichiometric Cu(OAc)₂ and para-toluenesulfonamide.

Scheme 6: Comparative study of meta-substituted versus para-substituted substrates
We were interested to note that in all of the cases examined the trifluoroacetamide is superior to that of the sulfonamide, both in terms of milder conditions and higher yield. The reactivity and selectivity trends observed in the C-H amidation of various aromatic oxazolines with trifluoroacetamide and sulfonamides is intriguing, and our observations highlight some unexpected trends. In particular, we felt that the low reactivity observed in the cases of dimethylamino-functionalized aromatics, and the meta-methoxy aromatic substrates, together with the unusual regioselectivity observed with the meta-fluoro substrate were particularly intriguing and warranted further investigation. Accordingly, we decided to conduct deuterium labelling experiments and these are shown in Scheme 7. We conducted the reaction between 3-methoxy aryloxazoline 15 and para-toluenesulfonamide in the presence of deuterated methanol, and observed 74% mass recovery. The mixture did not contain
amidation product, but we observed almost quantitative deuterium incorporation affording a mixture of mono- and di-deuterated materials 39 and 40. This result confirms that rhodacyle formation proceeds under the reaction conditions, but suggests that the problematic step in the catalytic cycle is related to the formation of Rh(V)-nitrenoid species B. Although the origin of this effect await further study, it may be that the presence of an electron donating meta-substituent (with respect to the directing group) results in a strengthening the carbon-rhodium bond in rhodacyle A retarding nitrene insertion, or that strong electron donation reduces the propensity for formation of Rh-nitrenoid intermediates. In addition, running the same reaction of 3-dimethylamino aryl oxazoline 41 resulted in <5% deuterium incorporation (as judged by 400 MHz $^1$H NMR spectroscopy) and only recovery of the starting material, suggesting that slow cyclometallation is occurring in this case. Finally, carrying out the deuterium labelling experiment with the meta-fluoro aryloxazoline we were able to observe a mixture which contained C-H amidation product 37 and a 1:1 mixture of recovered starting material and mono C2 deuterated starting material. The observation of C2-selective mono deuteration indicated that it is likely that selective rhodacyle formation gives rise to the observed product, rather than product determining nitrene insertion. We believe the selective rhodacyle formation is a result of the enhanced acidity of the proton ortho to the fluoro substituent.

Scheme 7: Deuterium incorporation studies and abbreviated mechanism
Finally, in order to show the potential of this method for synthesis of functionalized scaffolds we targeted the C-H amidation of 2-chloropyridine 44 (scheme 8). This substrate underwent smooth amidation and in high regiocontrol to generate 45. Subsequent hydrolysis of the acetamide followed by the oxazoline delivered aza-anthranilic ester 46 in acceptable overall yield.

Scheme 8: Synthesis of multi-functionalized heterocycles
In conclusion, we have described the extension of our rhodium-promoted C-H amidation conditions to sulfonamide amino sources. We found a reaction temperature of 100 °C was key to affording efficient amidation with a range of aryl and alkyl sulfonamides, and that a range of functionalized oxazoline scaffolds were well tolerated. Through investigation and comparative study, we found aryl oxazolines with electron donating meta-substituents were incompatible with the reaction system whilst their para-substituted counterparts were highly successful. Mechanistic studies suggested this could be due to the inhibition of the formation of key Rh(V)-nitrenoid species, or a slow nitrene insertion step. Additionally, we observed the opposite regioselectivity of amide insertion with 3-fluoro aryloxazoline and determined this observation to be the result of regioselective rhodacycle formation.

**Experimental Section**

The following substrates were prepared according to a previously reported procedures 2-(p-tolyl)-4,5-dihydrooxazole, 2-(4-methoxyphenyl)-4,5-dihydrooxazole (20), 2-(4-trifluoromethylphenyl)-4,5-dihydrooxazole, 2-(4-bromophenyl)-4,5-dihydrooxazole, 2-(4-fluorophenyl)-4,5-dihydrooxazole, methyl 3-(4,5-dihydrooxazol-2-yl)benzoate and 2-(2-chloropyridin-4-yl)-4,5-dihydrooxazole (44).

General procedure A: Amide Synthesis. To a dried round bottomed flask was added ester (1.0 eq.) and heated to 55 °C with stirring. Upon reaching the desired temperature ethanolamine (1.5 eq.) was added slowly via syringe and the reaction was stirred for 3 h before cooling to room temperature, and stirring for a further 18 hours. The crude reaction mixture was then
purified by recrystallisation or flash column chromatography on silica gel eluting with dichloromethane and methanol (1% MeOH to 20% MeOH) or ethyl acetate (100%) to afford the amide products.

Synthesis of N-(2-hydroxyethyl)-3-methoxybenzamide\textsuperscript{15}. Following general procedure A, using ethyl 3-methoxybenzoate (3.09 g, 17.2 mmol) and ethanolamine (1.57 g, 25.8 mmol) the amide product was afforded as a yellow oil (3.18 g, 95%). \textsuperscript{1}H NMR (400 MHz, CDCl\textsubscript{3}): \( \delta \) 7.35 (1H, s), 7.29 (2H, dd, \( J = 4.0, 2.5 \) Hz), 7.05 – 6.93 (2H, m), 3.82 – 3.77 (5H, m), 3.58 (2H, app dd, \( J = 10.0, 5.0 \) Hz); \textsuperscript{13}C{\textsuperscript{1}H} NMR (100.6 MHz, CDCl\textsubscript{3}): \( \delta \) 168.7, 159.9, 135.7, 129.7, 119.0, 117.9, 112.5, 62.2, 55.5, 43.0.

Synthesis of 3-fluoro-N-(2-hydroxyethyl)benzamide\textsuperscript{16}. Following general procedure A, using ethyl 3-fluorobenzoate (2.29 g, 13.6 mmol) and ethanolamine (1.25 g, 20.4 mmol) the amide product was afforded as a yellow oil (1.62 g, 65%). \textsuperscript{1}H NMR (400 MHz, DMSO-d\textsubscript{6}): \( \delta \) 8.53 (1H, s), 7.74 – 7.68 (1H, m), 7.65 (1H, ddd, \( J = 10.0, 2.5, 1.5 \) Hz), 7.51 (1H, td, \( J = 8.0, 6.0 \) Hz), 7.42 – 7.32 (1H, m), 3.51 (2H, q, \( J = 6.0 \) Hz), 3.33 (2H, q, \( J = 6.0 \) Hz); \textsuperscript{13}C{\textsuperscript{1}H} NMR (100.6 MHz, DMSO-d\textsubscript{6}): \( \delta \) 164.9 (d, \( J = 2.0 \) Hz), 161.9 (d, \( J = 244.0 \) Hz), 136.9 (d, \( J = 6.5 \) Hz), 130.4 (d, \( J = 8.0 \) Hz), 123.3 (d, \( J = 2.5 \) Hz), 117.9 (d, \( J = 21.0 \) Hz), 114.0 (d, \( J = 22.5 \) Hz), 59.6, 42.3; \textsuperscript{19}F NMR (376.5 MHz, DMSO-d\textsubscript{6}); \( \delta \) – 113.0.

General procedure B: Amide Synthesis. To a stirred solution of benzoic acid (1.0 eq.) in dry dichloromethane (0.2 M) at 0 °C was added oxalyl chloride (3.0 eq.) and DMF (few drops). The reaction was allowed to warm to room temperature and stirred for a period of 3 hours before removing the solvent in vacuo. The crude residue was then dissolved in dry dichloromethane (0.2 M) and cooled to 0 °C using an ice bath. Triethylamine (3.0 eq.) was then added, followed by ethanolamine (3.0 eq.) via syringe. The reaction was allowed to warm to room temperature and stir overnight. The reaction mixture was then dry loaded onto
silica gel and purified by flash column chromatography on silica gel eluting with dichloromethane and methanol (0 to 10% MeOH) to afford the amide products.

Synthesis of 4-(dimethylamino)-N-(2-hydroxyethyl)benzamide. Following general procedure B, using 4-dimethylaminobenzoic acid (1.00 g, 6.05 mmol), oxalyl chloride (2.31 g, 18.2 mmol) and DMF (few drops) in dichloromethane (30 mL), then ethanolamine (1.11 g, 18.2 mmol), triethylamine (1.84 g, 18.2 mmol) and dichloromethane (30 mL) the amide product was afforded as a colorless amorphous solid (763 mg, 61%). FTIR: $\nu_{\text{max}}$ / cm$^{-1}$ (neat) 3362 (m), 2943 (w), 2871 (w), 1609 (m), 1205 (m), 1056 (m); $^1$H NMR (400 MHz, MeOD-d$_4$): $\delta$ 7.89 – 7.50 (2H, m), 6.93 – 6.52 (2H, m), 3.69 (2H, t, J = 6.0 Hz), 3.48 (2H, t, J = 6.0 Hz), 3.00 (6H, s); $^{13}$C{$^1$H} NMR (100.6 MHz, MeOD-d$_4$): $\delta$ 170.7, 154.3, 129.7, 121.9, 112.1, 61.9, 43.4, 40.2; HRMS: m/z [MH]$^+$ C$_{11}$H$_{17}$N$_2$O$_2$ calcd. 209.1285, found 209.1288.

Synthesis of 3-(dimethylamino)-N-(2-hydroxyethyl)benzamide. Following general procedure B, using 3-dimethylaminobenzoic acid (1.00 g, 6.05 mmol), oxalyl chloride (2.31 g, 18.2 mmol) and DMF (few drops) in dichloromethane (30 mL), then ethanolamine (1.11 g, 18.2 mmol), triethylamine (1.84 g, 18.2 mmol) and dichloromethane (30 mL) the amide product was afforded as a yellow oil (626 mg, 50%). FTIR: $\nu_{\text{max}}$ / cm$^{-1}$ (neat) 2807 (w), 1636 (m), 1598 (m), 1350 (m), 1055 (s), 994 (s); $^1$H NMR (400 MHz, CDCl$_3$): $\delta$ 7.29 – 7.22 (2H, m), 7.02 (1H, d, J = 8.0 Hz), 6.87 (1H, d, J = 8.0, 2.5 Hz), 6.68 (1H, br s), 3.85 – 3.80 (2H, app m), 3.62 (2H, app dd, J = 10.0, 5.5 Hz), 2.99 (6H, s); $^{13}$C{$^1$H} NMR (100.6 MHz, CDCl$_3$): $\delta$ 169.6, 150.6, 135.2, 129.4, 115.8, 114.7, 111.7, 62.8, 43.2, 40.9; HRMS: m/z [MH]$^+$ C$_{11}$H$_{17}$N$_2$O$_2$ calcd. 209.1285, found 209.1286.

Synthesis of methyl 4-((2-hydroxyethyl)carbamoyl)benzoate. Following general procedure B, using 4-(methoxycarbonyl)benzoic acid (1.00 g, 5.55 mmol), oxalyl chloride (2.11 g, 16.6 mmol) and DMF (few drops) in dichloromethane (28 mL), then ethanolamine (1.01 g, 16.7
mmol), triethylamine (1.68 g, 16.7 mmol) and dichloromethane (28 mL) the amide product was afforded as a colorless amorphous solid (820 mg, 66%). FTIR: $\nu_{\text{max}}$ cm$^{-1}$ (neat) 3330 (w), 3287 (w), 1714 (m), 1633 (m), 1550 (m), 1283 (s), 1111 (s), 1052 (s); $^1$H NMR (400 MHz, MeOD-d$_4$): $\delta$ 8.11 – 8.07 (2H, m), 7.94 – 7.90 (2H, m), 3.93 (3H, s), 3.72 (2H, t, $J =$ 6.0 Hz), 3.52 (2H, t, $J =$ 6.0 Hz); $^{13}$C{$^1$H} NMR (100.6 MHz, MeOD-d$_4$): $\delta$ 169.5, 167.7, 139.9, 133.9, 130.6, 128.5, 61.5, 52.9, 43.7; HRMS: m/z [MH]$^+$ C$_{11}$H$_{14}$NO$_4$ calcd. 224.0917, found 224.0920.

General procedure C: Oxazoline Synthesis. To a dried round bottomed flask was added amide (1.0 eq.) and dry dichloromethane (0.6 M). With stirring NEt$_3$ (1.9 eq.) was then added, followed by DMAP (0.2 eq.) and p-TsCl (1.7 eq.). The reaction mixture was allowed to stir at room temperature overnight, before being diluted with dichloromethane and water. The mixture was then transferred to a separating funnel and the layers partitioned. The aqueous layer was further extracted with dichloromethane. The combined organic layers were dried over anhydrous MgSO$_4$, filtered and the solvent was removed in vacuo. The crude residue was dissolved in MeOH (0.5 M) and NaOH pellets (3.0 eq.) were added in one portion. The reaction mixture was stirred at room temperature for 1 – 3 h before removing the solvent in vacuo. The residue was dissolved in dichloromethane and water, and transferred to a separating funnel. The layers were partitioned and the aqueous layer was further extracted with dichloromethane and ethyl acetate. The combined organic layers were dried over anhydrous MgSO$_4$, filtered and the solvent was removed in vacuo. The residue was purified by flash column chromatography on silica gel eluting with petroleum ether (40/60) and ethyl acetate (0% ethyl acetate to 100% ethyl acetate) to afford the oxazoline products.

Synthesis of 4-(4,5-dihydrooxazol-2-yl)-N,N-dimethylaniline. Following general procedure C, using 4-(dimethylamino)-N-(2-hydroxyethyl)benzamide (690 mg, 3.31 mmol), p-TsCl (1.07 g, 5.63 mmol), NEt$_3$ (636 mg, 6.29 mmol), DMAP (81 mg, 0.66 mmol) and dichloromethane
(5.5 mL), then using NaOH pellets (400 mg, 9.93 mmol) and MeOH (6.6 mL), the oxazoline product was afforded as a colorless amorphous solid (347 mg, 55%). FTIR: $\nu_{\text{max}}$ cm\(^{-1}\) (neat) 2970 (w), 1641 (m), 1503 (m), 1350 (m), 1324 (m), 1187 (s), 1159 (s), 1066 (s); $^1$H NMR (400 MHz, CDCl\(_3\)): $\delta$ 7.79 – 7.73 (2H, m), 6.64 – 6.58 (2H, m), 4.30 (2H, t, J = 9.5 Hz), 3.94 (1H, t, J = 9.5 Hz), 2.94 (6H, s); $^{13}$C\{$^1$H\} NMR (100.6 MHz, CDCl\(_3\)): $\delta$ 165.0, 152.1, 129.4, 114.8, 111.0, 54.6, 40.0; HRMS: $m/z$ [MH]$^+$ C\(_{11}\)H\(_{15}\)N\(_2\)O calcd. 191.1179, found 191.1180.

Synthesis of 3-(4,5-dihydrooxazol-2-yl)-N,N-dimethylaniline (41). Following general procedure C, using 3-(dimethylamino)-N-(2-hydroxyethyl)benzamide (577 mg, 2.77 mmol), p-TsCl (898 mg, 4.71 mmol), NEt\(_3\) (532 mg, 5.26 mmol), DMAP (68 mg, 0.55 mmol) and dichloromethane (5.0 mL), then using NaOH pellets (332 mg, 8.31 mmol) and MeOH (6.0 mL), the oxazoline product 41 was afforded as a colorless amorphous solid (272 mg, 52%). FTIR: $\nu_{\text{max}}$ cm\(^{-1}\) (neat) 2977 (w), 1646 (m), 1591 (s), 1496 (s), 1433 (s), 1367 (s), 1350 (s), 1253 (s), 1238 (s), 1066 (s); $^1$H NMR (400 MHz, CDCl\(_3\)): $\delta$ 7.36 – 7.33 (1H, m), 7.32 – 7.27 (2H, m), 6.86 (1H, dt, J = 7.0, 2.5 Hz), 4.44 (2H, t, J = 9.5 Hz), 4.07 (2H, t, J = 9.5 Hz), 3.00 (6H, s); $^{13}$C\{$^1$H\} NMR (100.6 MHz, CDCl\(_3\)): $\delta$ 165.5, 150.5, 129.1, 128.4, 116.5, 115.6, 112.0, 67.6, 54.9, 40.7; HRMS: $m/z$ [MH]$^+$ C\(_{11}\)H\(_{15}\)N\(_2\)O calcd. 191.1179, found 191.1180.

Synthesis of 2-(3-methoxyphenyl)-4,5-dihydrooxazole (15)\(^{17}\). Following general procedure C, using N-(2-hydroxyethyl)-3-methoxybenzamide (1.00 g, 5.12 mmol), p-TsCl (1.66 g, 8.71 mmol), NEt\(_3\) (984 mg, 1.36 mmol), DMAP (125 mg, 1.02 mmol) and dichloromethane (8.5 mL), then using NaOH pellets (614 mg, 15.4 mmol) and MeOH (10.2 mL), the oxazoline product 15 was afforded as a colorless solid (572 mg, 63%). Synthesis of 6-chloro-4-(4,5-dihydrooxazol-2-yl)pyridin-3-amine. To a round bottomed flask was added N-(6-chloro-4-(4,5-dihydrooxazol-2-yl)pyridine-3-yl)-2,2,2-trifluoroacetamide (680 mg, 2.31 mmol) and methanol (23 mL). NaOH pellets (277 mg, 6.93 mmol) were then added and the reaction mixture was stirred at room temperature for 18 hours. The reaction mixture was concentrated, dissolved in ethyl acetate and deionised water and transferred to a separating funnel. The layers were partitioned and the aqueous layer was further extracted with ethyl acetate. The combined organic layers were dried over anhydrous MgSO$_4$, filtered and the solvent was removed in vacuo to afford the aniline product as colourless solid (364 mg, 80%). Synthesis of ethyl 5-amino-2-chloroisonicotinate (46). To a round bottomed flask equipped with a reflux condenser was added 6-chloro-4-(4,5-dihydrooxazol-2-yl)pyridin-3-amine (50 mg, 0.25 mmol) followed by ethanol (6.3 mL) and concentrated H$_2$SO$_4$ (0.7 mL). The reaction mixture was stirred and heated at reflux for 20 h. The reaction was then allowed to cool to room temperature and diluted with water. The reaction mixture was then neutralised to pH 6 using a saturated aqueous solution of NaHCO$_3$ and transferred to a separating funnel with ethyl acetate. The layers were partitioned and the aqueous layer was further extracted with ethyl acetate. The combined organic layers were then dried over anhydrous MgSO$_4$, filtered and the solvent was removed in vacuo. The residue was purified by flash column chromatography on silica gel, eluting with petroleum ether (40/60) and ethyl acetate (0% to 40% ethyl acetate) to afford the ester product 46 as an orange amorphous solid (20 mg, 40%).
