Key Recommendations from the MedtechHTA Project

Keywords: medical devices, health technology assessment, MedtechHTA, methods, recommendations, economic evaluation

For Peer Review

ABSTRACT

There are particular characteristics of Medical Devices, such as the device-user interaction, the incremental nature of innovation and the broader organizational impact that lead to additional challenges for health technology assessment (HTA). The project explored key aspects of the conduct and methods of HTA for MDs. Systematic reviews and original research studies were conducted to determine improvements in processes and methods that could enhance the potential for HTA and optimize the diffusion of MDs.

Regulatory processes for MDs should be more closely aligned, the HTA evaluative framework should be harmonized and processes for conditional coverage and evidence development should be used. The methods for HTA should consider MDs as complex interventions, require the establishment of high quality registries, consider an iterative approach to the evaluation over time, recognize and allow for the particular characteristics of devices and use appropriate approaches for confounder adjustment in comparative effectiveness studies. To optimize the diffusion a common classification should be developed across countries in order to facilitate international comparisons, factors driving diffusion should be explored in HTA reports and physicians' personal goals and motivation should be better understood.

The key recommendations of the MedtechHTA project should improve the conduct and use of HTA for MDs.

1. Introduction

In this paper we present the key recommendations from the MedtechHTA project, organized under three themes (i) improving the process for HTA of medical devices (ii) developing methods for HTA of medical devices and (iii) optimizing the diffusion of medical devices. In each case we outline the issues that the recommendations seek to address, followed by the recommendations themselves. The research underpinning them is described in the papers emanating from the respective work packages, including the other papers in this supplement.

2. Improving the process for HTA of medical devices

The major issues identified regarding the process for the HTA of medical devices were that (i) the procedures for granting market access to new devices did not always encourage the generation of the clinical data, prior to product launch, necessary to undertake reliable HTAs, and (ii) that the specific characteristics of medical devices (eg the learning curve) were not explicitly considered in the methods guidelines of those organizations conducting HTAs. Furthermore, since the clinical evidence base is often not mature when devices are granted market access, an approach that encourages the generation of more data after product launch is required.

In their paper in this supplement, Ciani et al (2016) argue that (i) more stringent requirements supported by appropriate methodological choices are needed to provide clinical trial data for high-risk devices (ii) post-marketing surveillance based on device and user real world data should be encouraged

1
2
3 (iii) international harmonisation of practices will benefit the manufacturers and
4
5 (iv) progressive alignment of regulatory and HTA evaluation for parallel
6
7 submissions will improve efficiency in the health systems and promote timely
8
9 access to affordable effective technologies.
10

11 Additionally, in their paper Rothery et al (2016) point out the issues relating to
12
13 uncertainty and the value of research specific to devices: learning curve effects,
14
15 incremental device innovation, investment and irrecoverable costs, and dynamic
16
17 pricing. They show the circumstances under which requiring additional research
18
19 after product launch, accompanied by conditional approval for reimbursement,
20
21 may be an appropriate policy choice. They also show how the value of additional
22
23 research might be shared between the manufacturer and health sector to help
24
25 inform who might reasonably be expected to conduct the research needed.
26
27

28
29 Against this background, we make the following recommendations.
30
31

32
33
34 *Recommendations A: Improving the process for HTA of medical devices*
35
36

37
38
39 *A1. Align regulatory and HTA processes for devices with respect to data*
40
41 *requirements, through:*
42

- 43 - *joint scientific advice by regulatory and reimbursement bodies for data*
44 *collection for the device industry*
- 45
46 - *designing studies that allow collection of data on effectiveness that*
47
48 *jointly fulfill the requirements of regulators and payers*
49
50

51
52
53
54 *A2. Harmonize the HTA evaluative framework (collection & synthesis of*
55
56 *clinical evidence and economic evaluation) for devices across international*
57
58
59
60

1
2
3 HTA agencies, through:

- 4
5 - developing a standardized international risk classification for MDs
6
7 - determining appropriate levels of evidential requirements by risk
8
9 category
10

11
12
13
14 A3. Recognize that assessment of expected cost-effectiveness is not
15
16 sufficient: conditional coverage and evidence development decisions should
17
18 be assessed
19

- 20
21 - the value of the device and future value of research needs to be
22
23 quantified and used to identify the optimal timing of reimbursement
24
25 decisions in the device's life cycle
26
27 - implementation may commit resources that cannot be recovered
28
29

30
31
32 A4. Consider the implications of the learning curve (LC) on policy decisions
33
34 (and vice versa)
35

- 36
37 - the LC does not only change the estimate of effectiveness but also
38
39 affects the uncertainty in the decision
40
41 - identify the mechanisms of learning likely to cause change over time
42
43 and assess the profile of investment risk according to user experience
44
45 affected by the rate of uptake of the device in practice
46
47

48
49 A5. Consider the likely prospects of research and who should pay for it

- 50
51 - is it priority for public funding or for manufacturers to undertake?
52

60

3. Developing methods for HTA of medical devices

The methods for assessing the clinical and cost-effectiveness of medical devices need to adhere to the general standards for all health technologies, but also take account of the specific characteristics of medical devices. These include the existence of the learning curve, incremental innovation, dynamic pricing and organizational impact. The reviews of the literature conducted for the MedtechHTA project found that, although the general standards were good, more attention needs to be paid to these specific characteristics. In terms of the assessment of comparative effectiveness, it is best to consider procedures involving the use of medical devices to be 'complex interventions'. In terms of economic evaluation, the changes due to the learning curve, incremental innovation, dynamic pricing and organizational impact need to be modeled adequately.

Other key challenges relate to the relative lack of randomized controlled trials, as compared with pharmaceuticals, and the inherent uncertainty about clinical and cost-effectiveness at the time of product launch. Therefore, efforts may be necessary to collect data on safety and effectiveness post-launch. In addition, because of the likely reliance on observational studies, such as registries, appropriate methods of bias-adjustment need to be applied. Finally, the decision to approve, or not approve, a new device for reimbursement is closely linked to the decision on whether to collect more data and the nature of the data collected.

In their paper in this supplement, Schnell-Inderst et al (2016) consider medical devices to be complex interventions and argue that evaluation of their clinical

1
2
3 effectiveness differs in some aspects from the evaluation of pharmaceuticals.
4
5 One of the main challenges they identify is the lack of robust evidence and a
6
7 need for combining experimental and observational studies (OS) in
8
9 quantitative evidence synthesis accounting for internal and external biases.
10
11 They address this challenge by performing an elicitation exercise to determine
12
13 the strength of belief of methodological and clinical experts regarding the size
14
15 of internal and external bias affecting estimates of treatment effect estimates.
16
17 These bias-adjusted treatment effects were then fed into a generalized
18
19 evidence synthesis. In the evidence synthesis, they applied frequentist and
20
21 Bayesian statistical models using relative risks with 95% confidence/credibility
22
23 intervals as effect estimates.
24
25
26

27
28 Although such bias-adjusted estimates of treatment effects can be useful for
29
30 economic evaluations in situations where there is a relative lack of controlled
31
32 clinical studies, economic studies also need to consider the effects, on costs
33
34 and benefits, of the particular characteristics of medical devices, such as the
35
36 learning curve, incremental innovation and organizational impact. In their
37
38 paper in this supplement, Tarricone et al (2016) point to the inadequacies in
39
40 existing economic evaluations and make recommendations for improvements
41
42 in future studies.
43
44

45
46 A major challenge is to obtain an accurate estimate of the impact of the
47
48 learning curve. In their paper in this supplement, Varabyova et al (2016)
49
50 demonstrate how this can be done by using administrative data on over
51
52 40,000 patients admitted with unruptured abdominal aortic aneurysm to 553
53
54 different hospitals over the years 2006 to 2013. They examine two patient
55
56
57
58
59
60

1
2
3 outcomes, namely, in-hospital mortality and length of stay (LOS) using
4 hierarchical regressions with random effects at the hospital level. The
5 estimated models control for patient and hospital characteristics and take
6 learning interdependencies between endovascular aneurysm repair (EVAR)
7 and fenestrated EVAR (fEVAR) into account. They argue that to foster the
8 consideration of learning in economic evaluations of medical devices a
9 general framework for estimating learning effects needs to be devised.
10
11

12
13
14
15
16
17
18
19 Finally, in their paper, Rothery et al (2016) develop a general framework for
20 considering the uncertainties in the economic evaluation of devices and
21 linking the gathering of additional information with policies on approval for
22 reimbursement.
23
24
25
26
27

28
29 Against this background, we make the following recommendations.
30
31

32
33
34 *Recommendations B: Developing methods for HTA of medical devices*

35
36 *B1. Refine existing methods (for collection and synthesis of clinical and*
37 *economic data) for handling the common 'complexities' of devices, including:*

- 38 - *synthesis of observational and trial evidence*
 - 39 - *incorporating learning curves into decision analytic models*
 - 40 - *recognizing the potential for incremental innovation*
- 41
42
43
44
45
46
47

48
49 *B2. Consider the MD-related intervention as a complex intervention; in*
50 *particular, include the intervention's components and the relation between*
51 *intervention, modifying factors and outcome in the formulation of the research*
52 *question*
53
54
55
56
57
58
59
60

1
2
3 *B3. Consider specific study designs and analysis methods, in addition to*
4 *general recommendations for RCTs, in order to assess the comparative*
5 *effectiveness of MDs*

- 6
7
8
9
10 - *these approaches should address challenges often associated with*
11 *devices, including rapid incremental development, the device/user*
12 *interface and effect modification by contextual factors*

13
14
15
16
17
18 *B4. Establish disease-based or device-based registries of high quality for the*
19 *long-term study of the effectiveness and safety of MDs.*

20
21
22
23
24
25 *B5. Design such registries to allow comparative analyses:*

- 26
27 - *routinely collecting information on possible confounding factors*
28
29 - *collecting information on treatment patterns to facilitate HTA*
30
31

32
33
34 *B6. Use appropriate methods for confounder adjustment in comparative*
35 *effectiveness or safety analyses and try to address residual confounding*

36
37
38
39
40
41 *B7. If data from large registries are available for inclusion in the evidence*
42 *synthesis in HTA, consider bias-adjustment based on expert elicitation as one*
43 *scenario in the sensitivity analysis.*

44
45
46
47
48
49 *B8. Document research using suitable existing reporting guidelines.*

50
51
52
53
54 *B9. Consider MD-specific application of guidance on the methods for*
55 *evidence synthesis from the framework on complex interventions.*
56
57
58
59
60

1
2
3 *B10. Assess the applicability of findings considering the challenges arising*
4 *from patient eligibility, user dependence, study design, and rapid evolution of*
5 *the technology*
6
7
8
9

10
11 *B11. In economic evaluations and HTAs of MDs, pay particular attention to*
12 *the particular characteristics of MDs and explore their quantitative impact on*
13 *cost-effectiveness as part of the study.*
14
15
16
17

18
19
20 *B12. Consider an iterative process to the evaluation of devices as additional*
21 *evidence and learning emerges over time*
22
23
24

25
26
27 *B13. Consider the likelihood of future price changes*
28

- 29
30 - *price influences the benefits of early approval and the benefits of*
31 *additional research*
32
33 - *it may be useful to identify effective price thresholds for which guidance*
34 *changes*
35
36
37

38
39
40 *B14. Determine whether manufacturers should be expected to conduct the*
41 *research, based on an assessment of:*
42
43

- 44
45 - *the commercial value to manufacturers of early evidence*
46
47 - *the potential for Approval with Research and for improving research*
48 *timelines*
49
50
51
52
53
54
55
56
57
58
59
60

4. Optimizing the diffusion of medical devices

Optimizing the use of medical devices would involve ensuring that they are used only in situations where they are clinically and cost-effective. The review of the literature conducted in the MedtechHTA project showed that there are wide geographical variations in the use of implantable cardiac devices, but very little understanding of why these variations exist. In order to obtain a better understanding of the use of devices, it is important to have standardized methods of data collection, so that differences between regions and countries can be reliably studied.

In their paper in this supplement, Torbica et al (2016) report the first investigation of the determinants of temporal and geographical variations in pacemaker (PM) and implantable cardioverter defibrillator (ICD) implants and replacements at regional level across 5 EU countries. They found that (i) regional per capita GDP appears to have no effect on implant rates of cardiac implantable electrical devices (CIEDs) (ii) regions with greater proportion of residents with higher level of tertiary education, an aged population, and greater life expectancy have higher implant rates of CIEDs and (ii) higher numbers of implanting centres foster access to technologies.

This last finding suggests that it is important to gain a better understanding of the clinical, professional and organizational factors that encourage or discourage the use of the clinical procedures involving the use of devices.

Therefore, more study is required of the motivational factors facing patients, physicians and the institutions in which they work. In addition, attention needs to be paid to the relevant demographic factors and the impact of health care financing and organization.

1
2
3 Therefore, in their paper in this supplement, Hatz et al (2016) conducted a
4 comprehensive analysis to investigate which environmental, organizational,
5 individual and technological factors impact the adoption and utilization of
6 cardiovascular devices. The data were collected from a large-scale online
7 survey that was sent to members of the European Society of Cardiology.
8
9 Seven random intercept hurdle models were estimated using the data
10 obtained from the survey. They found that better manufacturer support
11 increased the adoption probability of “new” devices (i.e., in terms of CE mark
12 approval dates), that budget pressure increased the adoption probability of
13 “old” devices and that larger hospitals and urban locations were associated
14 with higher adoption probabilities across devices. Other variables, such as
15 financial aspects, motivation or organizational effects of adoption, were not
16 statistically significant across models, suggesting that these factors are less
17 important than other factors for the adoption of devices.
18
19
20
21
22
23
24
25
26
27
28
29
30
31
32

33
34 Against this background, we make the following recommendations.
35
36
37

38 *Recommendations C: Optimizing the diffusion of medical devices*
39

40
41
42
43 *C1. Leverage routinely collected data (administrative data) to investigate the*
44 *adoption and diffusion of MDs, provided that coding system allows for valid*
45 *and reliable identification of the technology*
46
47
48

49
50
51
52 *C2. Endorse the use of a common classification for medical devices (unique*
53 *identification code) across countries to facilitate international comparisons*
54
55
56
57
58
59
60

1
2
3 C3. *Include factors driving adoption of medical devices systematically in HTA*
4
5 *reports to estimate the impact of the interplay of:*

- 6
7
8
 - 9 - *physician characteristics,*
 - 10 - *organizational, regional, environmental factors and manufacturers'*
11 *actions*

12
13
14
15
16 C4. *Consider divergent effects by stratifying by medical devices type (e.g.*
17 *"old" and "new" medical devices)*

18
19
20
21
22 C5. *Concentrate on the identification of key opinion leaders in hospital to*
23 *better understand the adoption and the diffusion process*

24
25
26
27
28 C6. *Focus on developing the understanding of physicians' personal goals and*
29 *motivation and their role in the adoption of medical devices*

30
31
32
33 C7. *Monitor manufacturers' actions, as they seem to be very relevant for the*
34 *adoption of "new" medical devices*

35
36
37
38
39 C8. *Consider regional (e.g. rural vs urban hospital location) and*
40 *environmental factors (e.g. GDP and out-of-pocket payment) to understand*
41 *where the diffusion process is likely to take place*

- 42
43
44
45
 - 46 - *in large hospitals, with relatively large specialist departments*
 - 47 - *in high income countries with lower shares of out-of-pocket payments*

48
49
50
51
52
53
54
55
56 **5. Future research**
57
58
59
60

1
2
3 Although the recommendations made by the MedtechHTA project will go a long
4 way towards improving the conduct and use of HTA for medical devices, the
5 project also identified several possible future research initiatives.
6
7
8
9

10 11 *5.1 Developing innovative approaches for the assessment of devices*

12 One of the recommendations made to improve the process for HTA of MDs
13 concerned the collection of data on effectiveness that jointly fulfill the
14 requirements of regulators and payers. One way of achieving this would be to
15 encourage regulators and payers to work more closely together. A number of
16 European collaborations already exist in the area of safety monitoring, such
17 as the European Databank on Medical Devices
18
19
20
21
22
23
24
25
26

27 ([https://cemarking.net/european-databank-for-medical-devices-to-boost-](https://cemarking.net/european-databank-for-medical-devices-to-boost-control/)
28 [control/](https://cemarking.net/european-databank-for-medical-devices-to-boost-control/)). The research in MedtechHTA identified some innovative approaches
29 for integrating the regulatory and health technology assessment, such as the
30 EXCITE programme in Ontario, Canada ([https://www.marsdd.com/systems-](https://www.marsdd.com/systems-change/mars-excite/mars-excite/)
31 [change/mars-excite/mars-excite/](https://www.marsdd.com/systems-change/mars-excite/mars-excite/)). In this programme, the data needs of future
32 HTA are anticipated early in the regulatory process.
33
34
35
36
37
38
39

40 In addition, whilst the MedtechHTA project established that the special
41 characteristics of MDs suggested some differences in the approach to HTA as
42 compared with pharmaceutical, further research is required to determine
43 which of these needs can be met by changes in organization and process, or
44 whether they require a completely different methodological approach.
45
46
47
48
49
50
51
52
53

54 *5.2 Estimating learning curves for medical devices*

55
56
57
58
59
60

1
2
3 The case study conducted as part of the project demonstrated that it is
4 possible to model the learning curve for devices. Since ideally it would be
5 desirable to predict the likely impact of the learning curve for a new device,
6 further research should be conducted to explore whether it is possible to
7 categorize devices in terms of their likely learning curve (eg according to
8 types of technologies (diagnostic or therapeutic), medical specialties, device
9 risk classes or a combination of different criteria). Then, if a new device were
10 developed in a given category, one might be able to predict its learning curve
11 in advance. Apart from helping determine the most appropriate approach to
12 determining the need for further research, this has organizational implications,
13 such as determining whether more complex devices should be concentrated
14 in a small number of centres, where users can be adequately trained. In fact,
15 the learning effect does not attain to the use and experience with the new
16 device only but often also refers to a more complex system of attributes such
17 as the quality and quantity of clinical teams (eg level of training, incentives to
18 innovation), the level of capital equipment present in healthcare centres, the
19 types of centres and how they are organized and managed (e.g. district
20 hospitals vs independent trusts, models of care based upon levels of intensity
21 vs medical specialties). To investigate the learning effect of medical devices
22 as exclusively depending upon number of procedures delivered by clinicians
23 can therefore be a narrow approach. The learning curve may reach its steady
24 state with a relatively low number of procedures but with a high attention to
25 patients' selection or with a good level of interactions between clinical teams
26 in the hospitals (eg interventional cardiologists and surgeons for cardiac
27 procedures implying new cardiac devices). Further research aimed at
28
29
30
31
32
33
34
35
36
37
38
39
40
41
42
43
44
45
46
47
48
49
50
51
52
53
54
55
56
57
58
59
60

1
2
3 investigating and measuring the impact of learning curve onto costs and
4
5 outcomes of the introduction of medical devices need therefore to identify all
6
7 potential explicative variables as independent variables to be included in the
8
9 model.
10

11 12 13 14 *5.3 Use of observational data in assessing the comparative effectiveness of* 15 16 *devices*

17
18 The case study on the use of bias-adjustment should be repeated for other
19
20 devices in order to confirm its promise. In addition, while the case study
21
22 considered bias-adjustment in a situation where there was evidence from both
23
24 RCTs and observational data, in many situations there may only be
25
26 observational data. Therefore, future research could explore the use of these
27
28 methods in those situations, particularly if an RCT were planned or ongoing in
29
30 order to compare with the results of the bias-assessment based only on the
31
32 observational data.
33
34
35
36
37

38
39 In addition, although registries are commonly used to assess the safety and
40
41 longevity of devices, further research is required to determine how the design
42
43 of such registries would need to be adapted to facilitate economic evaluation.
44
45 A critical feature would be for registries to be able help us assess the relative
46
47 effectiveness of treatments. In order to do so there needs to be treatment
48
49 variation, for example patients with similar characteristics receiving different
50
51 treatments within the registry. In addition, the risk categories of patients
52
53 should be classified in order to enable assessments of cost-effectiveness by
54
55 sub-groups, details of resource use are also required and, if important for the
56
57
58

8 9 10 *5.4 Studying the diffusion of devices*

11 The research in the project has added to our understanding of the factors
12 influencing the diffusion of devices, but there is still a large amount of
13 unexplained variation. Further research could be undertaken to explore the
14 extent to which the observed rates of device utilization were consistent with
15 research-based clinical guidelines where these exist. Further studies should
16 also investigate the impact on diffusion of the motivational factors facing
17 patients, surgeons and the institutions in which they work. Previous studies on
18 diffusion of medical technologies had pointed to the key roles of social
19 networks and peer communications rather than clinical guidelines and
20 published evidence (Rogers, 1995). However in recent times the role of
21 evidence has gained more attention and has become crucial for regulatory
22 and HTA bodies and for the scientific community at large. Today, variables
23 other than peer communication can influence clinicians' beliefs and attitude
24 towards the introduction of new medical technologies and need to be
25 investigated in order to achieve a better understanding of how the diffusion
26 process is evolving across time and across different jurisdictions.

49 50 *5.5 Coverage with evidence development for medical devices*

51 The research in the project set out a conceptual framework for the
52 assessment of policies for coverage with evidence development. Further
53 research could explore the actual implementation of such policies and explore
54
55
56
57
58
59

1
2
3 practical issues such as determining who should fund the research and issues
4
5 of study design. This is important in order to ensure the appropriate diffusion
6
7 of devices that have the potential to be clinical and cost-effective.
8
9

10
11 **6. Conclusions** The use of Health Technology Assessment has grown
12
13 dramatically worldwide over the last 20 years in order to determine the
14
15 appropriate level of reimbursement and coverage of medical technologies.
16
17 Nevertheless HTA has diffused having pharmaceuticals in mind. Recent
18
19 changes in the regulation of medical devices together with the fast pace of
20
21 innovation that characterize the industry of medical devices have turned the
22
23 attention to this class of medical technologies and raised the issue of whether
24
25 methods to assess pharmaceuticals effectively fit this other type of
26
27 technologies. While there is agreement on the consideration that medical
28
29 devices are different from drugs, it is not entirely clear whether these
30
31 difference really matter.
32
33
34
35

36 The project MedtechHTA has revealed that medical devices' key features make
37
38 their assessment more challenging than drugs and need to be considered in
39
40 order to correctly inform final policy recommendations.
41
42

43 Based on multiple methods, MedtechHTA has developed a three-year research
44
45 agenda aimed at improving current methods to assess MDs by issuing
46
47 several recommendations. Regulatory processes for MDs should be more
48
49 closely aligned, the HTA evaluative framework should be harmonized and
50
51 processes for conditional coverage and evidence development should be
52
53 used. The methods for HTA should consider MDs as complex interventions,
54
55 require the establishment of high quality registries, consider an iterative
56
57
58
59
60

1
2
3 approach to the evaluation over time, recognize and allow for the particular
4 characteristics of devices and use appropriate approaches for confounder
5 adjustment in comparative effectiveness studies. To optimize the diffusion a
6 common classification should be developed across countries in order to
7 facilitate international comparisons (GHTF, 2012), factors driving diffusion
8 should be explored in HTA reports and physicians' personal goals and
9 motivation should be better understood.
10
11

12 Taken together, the key recommendations of the MedtechHTA project should
13 improve the conduct and use of HTA for MDs. Several actors have been
14 identifies as relevant to improving the assessment of MDs. Regulatory bodies,
15 clinicians, patients, policy-makers, healthcare managers and analysts are all
16 called to play their part and to converge towards these key principles.
17
18

19 If any of the recommendations are implemented it will be important to assess
20 their impact. For example, will the various initiatives to encourage the
21 generation of more timely and higher quality medical evidence on MDs lead to
22 their more appropriate adoption and diffusion? Such evidence will be
23 important if the HTA of medical devices is to continue to develop.
