**Abstract:**
Semantic dementia is a rarer dementia, classified under frontotemporal dementia and primary progressive aphasia. Communication interventions in this condition have most often focussed on strategies to improve word retrieval. Less evident are studies examining conversation at home and interventions aiming to enhance participation in family life. Presented here is a case study of a family living with semantic dementia. Conversation analysis and narrative analysis allowed for detailed assessment of need and the design of an individually tailored life story intervention to facilitate interaction between them: a co-produced life story music DVD. This provided the family with a resource that allowed the person with semantic dementia to display areas of retained competence and enhanced participation in interaction in a way that was not typically present in everyday conversation. It is argued that fostering greater opportunities for such in-the-moment connections is an important goal for intervention.
Combining music and life story to enhance participation in family interaction in semantic dementia: Findings from a longitudinal case study

Introduction

Dementia is a syndrome that is caused by a range of conditions that affect the brain. Such conditions include Alzheimer’s disease and vascular disease as well as less common dementias, such as frontotemporal dementia (Alzheimer’s Society, 2015). Frontotemporal dementia is thought to account for between 5-10% of all cases of dementia (Alzheimer’s Disease International, 2009) and is a common cause of younger onset dementia (Onyike and Diehl-Schmid, 2013). Semantic dementia is one of the subtypes of frontotemporal dementia and presents with progressive communication difficulties arising out of changes to semantic memory (Neary et al., 1998; Gorno-Tempini et al., 2011). As semantic dementia presents with a prominent language disorder the condition may be classified, particularly within the North American and Australian literature, as the semantic variant of primary progressive aphasia (Gorno-Tempini et al., 2011).

Expressive speech in semantic dementia is described as fluent with word finding difficulties, semantic paraphasias and an increasing lack of content words as the disease progresses (Hodges and Patterson, 2007; Kertesz et al., 2010). In this condition the
changes with semantic memory are regarded as a central conceptual deficit. This is an important point because it is not just difficulties accessing knowledge that is thought to lead to symptoms, but loss of the knowledge itself. For this reason, people present with difficulties understanding and using words; however, the symptoms extend beyond words and this affects recognition and understanding of all other stimuli, including objects, faces, sounds, smells, touch and tastes (Bozeat et al., 2000; Luzzi et al., 2007). In contrast to Alzheimer’s disease, visuospatial skills in semantic dementia are relatively well preserved and, although episodic memory does become impaired with time, difficulties are often described in retrieving remote, rather than recent day-to-day, memories (Hodges and Patterson, 2007).

To date, studies examining communication in semantic dementia have largely focussed on the language disorder seen on cognitive testing, most commonly exploring the conceptual difficulties evident at a single word level in both expression and comprehension (Hoffman and Lambon Ralph, 2011; Author C and others, 2010). A smaller range of studies have examined connected speech and aspects of discourse (Sajjadi et al., 2012; Garrard and Forsyth, 2010). However, there are very few studies examining everyday conversation at home and the challenges this provides for the person with semantic dementia and their family members (but see Author A and others,
2003) or exploring others ways in which the person with semantic dementia participates in everyday family life.

The International Classification of Functioning, Disability and Health Framework (ICF) (World Health Organization, 2001) provides a useful framework to explore how interventions may potentially target different areas in semantic dementia, thus delivering contrasting outcomes in terms of brain structures, brain functions and, alternatively, activities and participation in daily life. Interventions aiming to change brain structures or chemistry through medication to arrest or slow down the disease process are not available currently in semantic dementia. The most common focus to intervention in the literature is direct therapy tasks with the person with semantic dementia to improve brain function, specifically language function, with practice of target words to improve word retrieval (Savage et al., 2014). Whilst reviews of these methods have shown improvement in treated words compared to non-treated words within the experimental design, debate remains about issues of maintenance and generalizability to everyday conversation (Carthecy-Goulart et al., 2013; Jokel et al., 2014). Less evident are studies focussing on activities and participation in daily life, for example, studies exploring dyadic interventions to enhance communication with family members (but see Cartwright and Elliott, 2009; Wong et al., 2009).
There is also a lack of guidance in the literature or in clinical guidelines as to if, or how, therapies used across the general field of dementia care can be applied to semantic dementia. Common interventions include reminiscence, life story work and communication skills training (Eggenberger et al., 2013; McKeown et al., 2006; Westerhof et al., 2010). However, as yet, such interventions have not been explored in semantic dementia. Moreover, it has been noted that the different presentation of recent and long term memory difficulties in semantic dementia may mean that reminiscence and life story work may not be appropriate or may need to be modified, as in the case study presented in this paper, for those living with this specific condition (Frontotemporal Dementia Toolkit, 2014; Author A and others, 2003).

To help commence a psychosocial evidence-base in semantic dementia, the following case study of Sarah [person with semantic dementia], Reg [husband] and Harriet [couple’s daughter] will outline how a life story music DVD was developed by the first author alongside the family to enhance the participation of Sarah in family interactions. The intervention and the associated outcomes are described, including an exploration of the resulting in-the-moment family connections.

Study Methods
Sarah and Reg (64 and 66 years old, respectively) were both retired and had been married for 43 years. They had one daughter, Harriet and two grandchildren, who lived locally and offered considerable support. Sarah had been diagnosed with semantic dementia four years before this research took place. A community psychiatric nurse visited regularly and a care package provided a designated support worker to take Sarah out shopping and to social clubs a number of times in the week. Sarah was aware that she had dementia and would make reference to her condition using this word and recognized that there had been changes in her memory and talking. Reg reported that Sarah’s personality and behaviour had also changed and that their lives were now heavily built around the routines that Sarah had developed since the onset of semantic dementia. One of the problematic issues for them both was that Sarah was experiencing recurring headaches and would ask Reg for pain relief every few minutes, even if she had just taken her tablets.

Participants were visited at home by the first author over an 18 month period, with 20 visits made in total. A case study design (Yin, 2009) used a mixed methods approach with the following aims: i) to gain in-depth insight into the everyday experiences of Sarah, Reg and Harriet around interaction; ii) to use this knowledge to plan and deliver an individually tailored intervention to enhance interaction in the home situation; iii) to explore the effects of the intervention on interaction and participation.
In the initial stages semi-structured interviews explored the participants’ lives both before and now living with semantic dementia, with 11 hours and 7 minutes of interviews audio-recorded and transcribed in full. This was analysed using thematic narrative analysis (Riessman, 2008). Author B and others (2003) advise that at its simplest level ‘narrative research and analysis is about asking for people’s stories, listening and making sense of them and establishing how individual stories are part of a wider ‘storied’ narrative of people’s lives’ (p.331). This approach was used to understand the interrelationship between identity, self and the social world for Sarah, now living with semantic dementia and her family members (Williams and Keady, 2008). Conversation at home was explored directly through analysis of video data taken of everyday conversations and analysed using conversation analysis (Hutchy and Woofitt, 2008). Conversation analysis analyses the part that both parties play in order to jointly negotiate the meaning within a given communicative context (Scheglof, 2003) and, therefore, offers an ideal method to explore the natural communicative behaviours of both the person with semantic dementia and their family members (Perkins et al., 1998). Participants were given a small video camera and asked to record natural conversation at home. They were free to choose where and when they recorded and the topic(s) of conversation. Researchers were not present when recordings were made. The aim was therefore to record a sample of everyday interaction at home including the challenges and skills for all participants. An initial 127 minutes and 49 seconds of video
were recorded and analysed. At a later stage, the effects of the life story music DVD on Sarah’s wellbeing and interaction with family members were also explored; this will be described later in this paper.

The study was approved by a National Health Service Registered Ethics Committee and was also approved by the research governance department at the National Health Service local organisation where the research took place. Names and some contextual/biographical information have been changed in order to maintain confidentiality.

**Pre-intervention Assessment**

Assessment indicated that whilst there were significant challenges in interaction due to Sarah’s semantic dementia, Reg had a good understanding of how to manage her communication needs and he displayed a remarkable level of patience, with a number of strategies to help them both cope. Conversation analysis revealed a reduced repertoire of topics of conversation with the same topics often recurring in Sarah’s talk. In addition Sarah was observed to repeatedly use certain questions and statements, particularly about the routine of the day. Reg reported that, at times, Sarah lacked appropriate emotional responses in conversation. He also conveyed that a lack of conversation in the household was an issue because outside of those recurring themes
identified, Sarah did not initiate interaction and trying to encourage her to participate in conversation could be difficult. Reg’s attempts to engage Sarah in conversation could at times be met with minimal acknowledgements from her, e.g. ‘mm’ or ‘oh’ as Extract 1 now illustrates.

**Extract 1 - Minimal responses**

In this extract Sarah and Reg are waiting for the support worker and Reg is trying to encourage Sarah to participate in the conversation. There are five instances of minimal responses (lines indicated with an arrow) from Sarah, i.e. monosyllabic responses, low in volume and accompanied by a lack of eye contact. There are only two other responses from Sarah (lines 008 and 021), where she looks to Reg, addresses his question briefly but she does not elaborate on her response. Overall, Sarah’s responses convey minimal participation in the interaction. Please see Appendix for transcription symbols.

```
001 R  Suzanne will fetch us out take
002    us out maybe somewhere for a meal an ride
003    round for you you can say you’ve been out
004    then (2.0) alright
→  005 S  mmm "yeah" (no eye contact)
006 R  now you didn’t sleep very well last night
007    did you
008 S  I don’t know (looks at Reg)
009 R  you was up and down all night long saying
010    that you couldn’t sleep
```
→ 011 S  mmm ((no eye contact))
 012 R  I thought you probably would’ve wanted to stop in bed a bit longer this morning
→ 014 S  [mmm] ((no eye contact))
 015 R  [but] you was up at half past seven and I thought you might have wanted to have a little sleep but you seemed to be awake again now
→ 019 S  mm ((no eye contact))
 020 R  do you feel tired
 021 S  not now ((looks at Reg))
 022 R  but seeing that you was up and down all through the night and you didn’t sleep at all you said
→ 025 S  mmm ((no eye contact))

Since assessment of the family’s everyday lives indicated that Reg had adapted well to changes in Sarah’s conversation abilities, it was felt that advice about communication techniques was not necessary. However, Sarah’s limited involvement in everyday interactions at home suggested that further opportunities for participation were indicated. This, therefore, raised the question of whether activities such as life story work could contribute to facilitating such occasions for enhanced and biographically-orientated social interaction and participation within everyday family life.

The Intervention: Life Story Music DVD

Sarah already had a printed and bound life story book and whilst the book was reported to have been useful at an earlier stage to encourage communication, it was now limited
as an aid to enhance conversation because Sarah had difficulty recognising many of the 
people and places portrayed in the photographs and remembering the events concerned, 
even with verbal explanation and prompting. This is consistent with reports of 
associative agnosia affecting understanding of faces and places, along with evidence of 
long term memory difficulties in semantic dementia (Hodges and Patterson, 2007).

Interviews with the family described that Sarah had a long standing interest in music 
and singing and that she still retained many of these abilities. This indicated that 
exploring music within life story work might be more successful and so the decision 
was made to make a life story music DVD with Sarah and her family. Together with 
Sarah, Reg and Harriet the first author compiled a list of songs that were meaningful to 
Sarah, either in the past or the present. These songs were played to her using either an 
audio or video clip of the particular artist, thus identifying the songs she particularly 
liked. Following this, video footage was recorded at home with Sarah singing with her 
family using these clips. Also recorded was a member of the family introducing each 
song, e.g. ‘We’ve chosen this song because we know you love RED’ to introduce Chris 
De Burgh singing ‘The Lady in Red’. Clips were uploaded into a popular DVD 
programme maker, including: family members introducing the artists and stating why 
the song was meaningful, various artists singing and footage of family members singing 
with Sarah. The videos were then organized appropriately with relevant title lines added.
on screen, e.g. the title of the DVD as an introduction (Thank You for the Music), family members’ names when they appeared on screen and linking title slides to give flow to the DVD, e.g. ‘and now for us all singing…(song name)’. Where possible atypical words were spelt with a regular spelling, e.g. the popular English singer ‘Cilla’ (Black) was spelt ‘Silla’ on screen, to help Sarah read as she was experiencing surface dyslexia and so had difficulty reading words with irregular spellings. Finally, a credits slide listed the names of the family members who took part. The video was shown to Sarah on two occasions to pilot and refine the format, once on a laptop computer and once on the screen of her television and alterations were made as appropriate. This included:

- Ensuring labels of family names appeared on screen throughout. This reduced Sarah saying ‘who’s that?’ as had been the case during piloting the video when names were not present.
- Altering the order of songs – the song ‘I like a nice cup of tea’ was initially first, however, this led to Sarah requesting tea from Reg even if she had just had a cup and this was, therefore, placed at the end.
- Ensuring all lyrics of songs appeared at the bottom of the screen, at the request of the family so they could all sing along more easily.
- A particular song was omitted as this made Sarah’s daughter upset as it reminded her of how her mum used to be prior to her dementia.
A final DVD was given with a cover using stills from the recording session and an explanation of life story work on the reverse. The DVD was 40 minutes long. Copies were given to Sarah and Reg and another to Harriet and her family.

**Outcomes of the Intervention**

In terms of exploring the effects of the intervention, the aim was to understand how the life story process and the life story music DVD contributed to Sarah’s social interaction and participation with family members and to her well-being in the here and now. Video and audio recordings of the session making the DVD and the two sessions with Sarah and Reg watching the piloted and final versions were analysed (82 minutes of video data and an additional 40 minutes of audio data). The principles of conversation analysis guided this process and the video and audio were examined in their entirety with salient recurring features noted. Collections were then made of these recurring features using transcriptions of the data including speaking and singing and these were subjected to further detailed analysis focusing on how the life story music DVD impacted on Sarah’s well-being and participation in interaction (see below). In order to capture aspects of the interaction for analysis, transcription of relevant body movements was included and photographs were added to further display embodied aspects (particularly where description of parts of the scene would not convey the whole scene). This data driven method was used to analyse recurring features, or moments in the data.
This method, therefore, draws from conversation analysis (Hutchby and Wooffitt, 2008) but also has overlaps with micro analytical approaches using video to explore the effects of music therapy (Wosch and Wigram, 2007). This approach allowed for a qualitative comparison between the recurring features during conversation with those during singing. Analysis revealed three recurring patterns, or outcomes, in the data that could then be broken down further into specific behaviours:

1. **Distraction from Distress**

2. **Facilitating Interaction**
   a. In response to the lyrics
   b. Making up own lyrics
   c. Embodied and emotional connections
   d. Interaction arising from the video process or watching the DVD

3. **Performance and Identity**
   a. Embellishments and over-singing
   b. Embodied performance
   c. Reaction from her audience.

These results will be presented and extracts from the video data used to further illustrate issues. In the following extracts bold type is used for singing and standard type for talking. Behaviours occurring simultaneously are bracketed, as is standard in
conversation analysis. Still photographs taken from the video have been used to illustrate important nonverbal aspects to the data.

**Area 1 - Distraction from Distress**

Engaging Sarah in song distracted her from her recurring worries about her headaches and requests for pain relief. This provided the foundations for enhanced participation in interaction. The effects of this distraction were particularly dramatic during the session making the DVD. On this occasion Sarah was initially in bed, with her family present in the lounge. Reg asked her to get out of bed, as he thought it might distract her, but she looked in pain and it seemed as though filming might have to be postponed. Video footage, however, revealed the transformative nature of the music and interaction within the first minute. At the start of the recording Sarah complains about her headache. There is no eye contact with Harriet who is sitting next to her; Sarah eyes are shut and she is looking ill whilst rubbing her head. However, as the music plays (Lady in Red, Chris de Burgh) she opens her eyes, looks at the artist on the laptop screen and then to the researcher, beginning to attend to the music (18 seconds). Sarah begins to move to the music and smile (23 seconds), make eye contact with Harriet (28 seconds) and start to sing (33 seconds). At 54 seconds, she appears happy and engaged in the song as evidenced by her voice, face and body movements. This level of engagement continues throughout this song. During this visit Sarah did not ask for headache tablets while the
music was playing but when the music stopped, she started to complain about her head and ask for tablets. At a later visit Sarah was again repeatedly asking for pain relief in the first hour (during normal conversation), rarely going more than five minutes between requests. However, whilst watching the 40 minutes of the completed DVD she did not request any tablets. The DVD did not eliminate all repetitive behaviours, as Sarah often still asked for food, cups of tea and chewing gum. It would seem, therefore, that music appeared to lift her mood and distract her from her worries about her head, rather than reduce all such behaviours.

**Area 2 - Facilitating Interaction**

There were a number of ways that the DVD facilitated interaction including: a) In response to the lyrics; b) Sarah making up her own lyrics; c) Giving rise to embodied emotional connections; d) Interaction arising from the video process or watching the DVD:

**a) In response to the lyrics**

The following extract illustrates that Sarah did not just sing the lyrics of the songs, at an automatic or perhaps ‘over-learnt’ manner; she often processed the meaning and used these words as a vehicle to interact with others:
Extract 2 - Interaction arising from lyrics

Here Harriet and Sarah are singing to a Tina Turner song, ‘Simply the Best’ (M = music).

001 M \[t\text{ear us apart}\\]
002 H \[t\text{ear us apart}\\]
003 S \((l\text{ooks at } H)\) no [no no] no chance no chance
004 H [no no]
005 M baby I would rather be [dead]
006 S dead no no we don’t
007 S want to die yet do we

In response to the lyric ‘\textit{tear us apart},’ Sarah looks to Harriet in line 003 and expresses her disagreement with that possibility: ‘\textit{no}’ and ‘\textit{no chance’}. Harriet also expresses ‘\textit{no}’ as they look at each other. Following the lyric ‘\textit{I would rather be dead}’ Sarah says to Harriet ‘\textit{we don’t want to die yet do we?’} The result is both affectionate and humorous.

b) Making up own lyrics

Sarah would sometimes make up her own lyrics, singing in tune and in time to the music, but with her own words. For example, with Tina Turner’s ‘\textit{Simply the Best},’ at a point where only the music is playing, Sarah sings her own lyrics to Harriet ‘\textit{ah ah I love you any time of day I can’t stay awake I love you so oh oh oh.’}

c) Embodied and emotional connections
Connections between family members were not just verbal but also embodied. The Cilla Black song, ‘You are my World’, is Sarah and Reg’s engagement song that Sarah sung to Reg on the night they got engaged at a family party. Sarah no longer remembers this association with the song but does still remember many of the lyrics and its distinctive tempo. On the two occasions Sarah is video recorded listening to this song, Sarah is seen to reach for Reg’s hand when she sings ‘my arms reach out to you for love’ thus demonstrating an embodied connection with him, as extracts 3 and 4 illustrate. The behaviours observed on both videos are remarkably similar, with Sarah and Reg holding hands while Sarah sings.

**Extract 3 - Embodied connection - engagement song 1**

This example is from the session making the DVD.

```
001 M  [So my arms reach out to you for love]
002 S  [So my arms reach out to you for love]
003     [(reaches over to Reg takes his hand)]
004 R   [(takes Sarah’s hand, smiling)]
```

002 – ‘reach out to you’

002 - 004 – ‘...for love.’
Extract 4 - Embodied connection - engagement song 2

This example is from a later session watching the DVD, as before Sarah reaches over to Reg, who is sitting next to her, taking his hand.

001 M  [So my arms reach out to you for love]
002 S  [So my arms reach out to you for love]
003    [(reaches over to Reg takes his hand)]
004 R  [(looks at Sarah, takes her hand)]

Sarah also makes embodied and emotional connections with Harriet, for example, when making the DVD she places her cheek to Harriet’s when singing about dancing ‘cheek to cheek’ and at the end of this song (Lady in Red) there is a particularly poignant exchange between them both, as illustrated in extract 5:

Extract 5 - Emotional connection

001 M  my lady in [red]
002 S  ↑ [re:] ed
003 H  I love you ((leans in joint eye contact))
004 S  I love you darlin’ I love you so: much
d) Interaction arising from making or watching the DVD

Sarah regularly commented on the video, or about seeing herself and her family on screen, e.g. ‘I love red [reading off screen] I do, I do love it’; ‘my baby girl’ [Harriet on screen]. She often seemed surprised and delighted to see her family on television. When watching the DVD Sarah often asked ‘who’s put me on telly Reg?’ with amazement, but was unable to retain any explanation as to why the DVD had been made. It was decided with Reg that saying it was because she had a good voice was the most easily understandable and helpful for her, as it reinforced a positive aspect of her retained identity.

Area 3 - Performance and Identity

With regard to being ‘a singer’, it was clear during interviews that this was an extremely important and distinct part to Sarah’s identity that she still retained, as she explained when watching the DVD: ‘you’ve not been a singer really have you Reg, I’ve always been a singer, I remember when I was a child when me mum was her’. The video also illustrates that Sarah does not just sing, she is seen to perform with the following aspects contributing to this sense of performance.

a) Embellishments and ‘over-singing’
There are numerous examples of Sarah creatively embellishing her performance by adding extra notes, pitch rises and falls and singing extra items such as ‘oh yeah’ as a professional performer might do, as illustrated in extract 6.

**Extract 6 – Embellishment**

In the following example Sarah is watching the DVD and singing to Roy Orbison’s ‘Pretty Woman.’

001 M I don't believe you you're not the truth
002 S no ((point - in time)) no ((point - in time))
003 M No one could look as good [as you]
004 S [as you]
005 S go
006 M mercy
007 S yeah

Here we see Sarah adding in extra embellishments such as two well timed ‘no’s’ (002) accompanied with emphatic ‘points’. In line 005 she adds ‘go’ before Orbison sings his distinctive ‘mercy’ to which Sarah responds ‘yeah’ in line 007.

b) Embodied performance

Across the data Sarah is observed to move along to the music. These movements seem less about communicating to others but more about her natural and unintended response to the music, as extract 7 demonstrates.
Extract 7 - Embodied performance

Here when singing to ‘Simply the Best’ with Harriet, Sarah holds out her hands much as a singer would do when performing (see photo and lines 003-004)

001 M [better than all the rest]
002 H [better than all the rest]
003 S [all the rest]
004 [(S holds out two palms)]

003-004 – ‘all the rest’

c) Reaction from ‘her audience’

Sarah’s sense of performance is added to by the reaction of those around her. She is centre stage when singing, both when making and when watching DVD. Those present look to Sarah and comment positively about her singing and encourage her to perform as extract 8 shows.

Extract 8 - Audience reaction
At a rather flamboyant end to ‘the Lady in Red,’ Reg comments positively on Sarah’s performance (003):

001 M my lady in [red]
002 S ↑ [re:] e:e: ed
003 R well done Sarah beautiful that

In other instances family members clap her performance. When watching herself on screen Sarah also indicates approval by clapping. In this way there is evidence of Sarah ‘reliving the moment’ with approval of her own performance abilities.

Summary of Outcomes

Prior to the introduction of the life story music DVD, Sarah’s participation in interactions with her family members through conversation was generally limited. She initiated little, and her responses were often minimal, as seen in Extract 1. When Sarah used questions or initiated topics these were typically drawn from a limited repertoire of utterances and topics of conversation. The introduction of the life story music DVD provided Sarah and her family with a resource which allowed Sarah to display areas of retained competence (such as singing and performing for an audience). The use of this resource resulted in the enhanced participation of Sarah in interactions with her family members. When using the music DVD, Sarah’s well-being also appeared to improve, as seen in the reduction of her complaints about her headaches.
Engaging with familiar and meaningful music had the power to enhance Sarah’s participation and involvement with her family both verbally and nonverbally in a way that was not typically present in everyday conversation. For example, in-the-moment analysis of the video data sees Sarah take an active part in both the process of making the DVD and in her reactions when watching it, with playful, humorous and emotional connections with family members displayed. Sarah is thus centre stage when singing, in contrast to conversation, where she can often take a more passive role. Sarah was able to display her identity as a competent singer through song and embodied performance. In this way the intervention was able to enhance Sarah’s abilities and participation within interaction in a way that by-passed her difficulties with language and conversation skills.

Sarah and her family reported that they were very happy with the DVD and that it had been shown to others visiting the house including Reg’s relatives, their neighbour, the community nurse and their support worker. They had developed a family joke teasing each other about who was the best singer. The process had led to other activities with their son-in-law making Sarah another DVD with another set of favourite songs. Harriet in particular, however, reported that whilst it was lovely to see her mum happy, sometimes when making the DVD, it also made her sad as it reminded her of how her mum used to be in the past and she compared this to how she was now, saying:
‘sometimes happy memories can also make you sad’. Reg reported a similar feeling, though perhaps to a lesser extent. A telephone call from Reg, six months after they had received the DVD, revealed that they still enjoyed watching it together, with Reg reporting ‘I’m surprised it’s not worn out, the amount of times she’s seen it’.

Discussion

The intervention outlined in this case study illustrates the way life story work can be used to enhance interaction between an individual with semantic dementia and members of her family. An important aspect to this work involved tailoring the intervention to the specific needs of the person with semantic dementia. In this case whilst a life story book had been of use in the earlier stages of Sarah’s condition, changes in her ability to recognize faces and in her long term memory limited current use to encourage conversation. Music and song, in contrast, was demonstrated to provide an opportunity for in-the-moment connections with her family and opportunities to display her positive identity as a singer. The format allowed Sarah to participate in interaction in a way that exploited her retained skills. The data demonstrate not just a range of verbal connections but embodied and emotional connections, including love, joy and humour. Author A and others (2003) argue that professional outcomes from life story work may be very different from the outcomes that family members value. For example, whilst professionals may focus on reducing negative behaviour or fostering certain abilities,
simply ‘having fun’ together might be highly valued by family members struggling to cope with dementia in their lives. At times it is easy for professionals to forget that dementia may, for some families, reduce the choices they have at their disposal to engage in positive experiences together as a family and this is where appropriately tailored life story work may offer potential. Watching the DVD allowed Sarah an opportunity to relive the moment and interact with her family. Reg indicated later that Sarah often enjoyed watching the DVD even after the intervention had been completed. As such it can be seen that the intervention had a continuing effect over the longer term, not in terms of a continuous change in functional abilities, but rather as a resource which provided recurring opportunities to foster positive interaction and participation.

A heightened liking for music, described as ‘musicophilia’, has been noted to be particularly common in frontotemporal dementia (Fletcher et al., 2013). This has implications for diagnosis as well as for broader understanding of the neurobiology of music within the human brain (Hailstone et al., 2009; Weinstein et al., 2011; Warren et al., 2011). In some reports excessive listening to music has been displayed as a problem behaviour (Boeve and Geda, 2001). The literature, however, lacks any detailed exploration of the benefits of music from the perspective of the person with semantic dementia or their family. For example, whilst music therapy has been explored in dementia generally (McDermott et al., 2013; 2014), less attention has been paid to this
as an intervention in frontotemporal dementia. Ridder and Aldridge (2005), however, describe how Mrs F, with advanced frontotemporal dementia, enjoyed singing familiar songs and a reduction in heart rate and antipsychotic medication was noted over the four week programme. In a later report, Ridder et al. (2009) explore various measures to develop a research protocol for music therapy in frontotemporal dementia.

This study demonstrates that the singing of familiar tunes can be used as a vehicle to provide opportunities for positive interaction and participation at home in semantic dementia. Sarah’s case illustrates the effects on interaction in detail and the positive benefit this has to Sarah in deploying retained abilities, displaying competence and showing aspects of her identity (for example, as a singer and also as a loving wife and mother). Moreover, the case demonstrates that music facilitates a different range of interactional skills compared to everyday conversation and evidences the reports in interviews that music has a special effect on Sarah’s well-being. For example, singing allows the playful and creative aspects of Sarah’s identity to be displayed and this is in contrast to observations of conversation, both before and after the intervention, where she is often relatively passive. The embellishments and over-singing that Sarah uses intensifies her sense of performance. Musical embellishments were also reported in a case study of a harpsichord player with semantic dementia and it is argued that such behaviours indicate that these musical skills are not merely being retrieved and played
out in a rote manner from long term memory but show innovation in musical delivery (Weinstein et al., 2011). This would also appear to be the case for Sarah as demonstrated by her performance skills, creativity with singing and her ability to process the words of the song and use this as a vehicle to interact with those around her.

Hailstone et al. (2009) argue that the relative sparing of musical knowledge may contribute to musicophilia in people with frontotemporal dementia. This raises the question as to whether such behaviours may, in part, be an adaptive response on the part of the person with semantic dementia, where the individual uses the skills they still have at their disposal to engage in activities that provide them with pleasure, i.e. repeatedly listening to music. Such observations have important implications for interventions. For example, a study of the practice of speech and language therapists working with people with semantic dementia reported that one of the founding principles of their work was a focus on ability and the promotion of this, rather than a focus on disability in therapy (Author A and others, 2003). This approach drew on the principles of person-centred dementia care practice (Brooker, 2007). Sarah’s case study illustrates that communication interventions may build on abilities outside of language to provide appropriate opportunities to contribute to interactional and emotional connections with family members. Importantly, in this case study singing was not just a solitary pleasure for Sarah but an activity that could engage others.
The biographical nature of the intervention enabled longstanding aspects of Sarah’s identity to be displayed within interaction, including behaviours of a performative nature. Performance is an area where the data intersect narrative analysis, conversation analysis and elements of performance studies with certain recurring behaviours from Sarah that can be viewed and analysed ‘as performance’ (Schechner, 2013, p.168). This performance observed in the present, was also often compared with elements of the past. For example, when observing her current behaviour when singing, Sarah’s family talked about her long standing love of singing and recalled stories of her singing abilities from her childhood through to her adult life. The interplay between how the present performance is positioned against the past is an important aspect of performance analysis within the fields of both narrative inquiry (Riessman, 2008; Phoenix et al., 2010) and performance studies (Schechner, 2013). Phoenix et al. (2010) argue that performance analysis is an attractive method because it can ‘explicitly illuminate how the researcher shapes and is shaped by the research process’ (p.7). This is an important point for an intervention study because the explicit aim here was to shape interactional and participatory behaviour. The life story work, however, also presented some challenges to family members. Sarah’s performance reminded her family of how she used to be. As Schechner (2013) notes ‘performances mark identities, bend time, reshape and adorn the body and tell stories’ (p.28) and Sarah’s performance, it could be argued, was in some ways an autobiographical performance in the present but also from
the past. Her family, as the audience, were aware this was only a moment and not a lasting performance and this also brought them some sadness.

There is no evidence that the music DVD had wider effects on Sarah’s interaction or well-being when it was not being used. For example, the video data shows that, once the music had stopped, Sarah returned to complaints about her headache. Similarly there is no evidence that the conversations between Sarah and her family differed in any ways which could be attributable to the use of the music DVD. However, this lack of generalisation should not detract from the in-the-moment effects on interaction and emotion evident in the data when the music DVD was being used. Thompson (2009) notes that in the search for the ‘effects’ of performance in terms of social utility, applied theatre is in danger of forgetting the ‘affect’ of performance at the time and this is a problem faced too by dementia care. It can be extremely difficult for families to engage individuals with advancing semantic dementia in activity or conversation of any kind. However, the achievement and creativity seen within such in-the-moment exchanges, as discussed here, can be too easily forgotten when a lack of ‘effect’ in the long term is noted. Dementia care would benefit from greater attention to such issues. Providing families with ways to exploit these in-the-moment opportunities within everyday interaction and experience emotions such as joy, fun, love and laughter seems an important goal for intervention. As Reg indicated in his telephone call six months after
the intervention had been completed, Sarah watched the DVD on many occasions. This recurring opportunity for the family members to engage in this way illustrates a particular kind of long term outcome; the life story music DVD gave them a resource they could use to facilitate connections and enhance Sarah’s well-being and her participation in family life.

**Conclusion**

This case study moved away from the focus evident in the literature on language function in semantic dementia to an intervention to enhance participation in life situations. Specifically, the life story work with Sarah aimed to foster participation in interaction at home, through manipulating opportunities in the environment. In this way, participation was the primary goal and so evaluating this had to be the relevant outcome measure, as demonstrated here through in-the-moment effects in interaction. Changes in behaviour and brain functions after the activity has finished, whilst welcome, are not necessary for the goals of the intervention to be achieved. Separating out these aspects is a crucial aspect to delivering person-centred care and interventions in dementia. This encourages practice and care to value such in-the-moment connections and seek to foster greater opportunities for these to occur in the daily lives of those living with semantic dementia and their family members.

</thead>
<tbody>
<tr>
<td>[</td>
<td>A large left-hand bracket links overlapping utterances or non-verbal actions at the point where the overlap begins.</td>
</tr>
<tr>
<td>]</td>
<td>A large right-hand bracket marks where overlapping utterances/simultaneous non-verbal actions stop overlapping.</td>
</tr>
<tr>
<td>e.g.</td>
<td>01 PR how have you been since I last saw [you]</td>
</tr>
<tr>
<td></td>
<td>02 AM [not] so good</td>
</tr>
<tr>
<td>(0.6)</td>
<td>Silences are marked in seconds and tenths of seconds, i.e. (0.6) is six tenths of a second; (1.2) is one second and two tenths of a second.</td>
</tr>
<tr>
<td>(.)</td>
<td>A full stop in single brackets indicates an interval of tenth of a second or less in the stream of talk.</td>
</tr>
<tr>
<td>oh :</td>
<td>A colon indicates an extension of the sound or syllable it follows (more colons prolong the stretch).</td>
</tr>
</tbody>
</table>
Marked rising and falling shifts in intonation are indicated by upward and downward pointing arrows immediately prior to the rise or fall.

Underlining indicates emphasis.

Degree signs indicate talk which is quieter than surrounding talk.

Double brackets represent a gloss or description of some non-verbal aspect of the talk

Bold type in this report indicates singing.
