THE QUANTUM LEFSCHETZ HYPERPLANE PRINCIPLE CAN FAIL FOR POSITIVE ORBIFOLD HYPERSURFACES

TOM COATES, AMIN GHOALAMPOUR, HIROSHI IRITANI, YUNFENG JIANG, PAUL JOHNSON, AND CRISTINA MANOLACHE

Abstract. We show that the Quantum Lefschetz Hyperplane Principle can fail for certain orbifold hypersurfaces and complete intersections. It can fail even for orbifold hypersurfaces defined by a section of an ample line bundle.

1. Introduction

Let $X$ be a projective algebraic variety. Let $g$ and $n$ be non-negative integers, $d$ be an element of $H_2(X; \mathbb{Z})$, and $X_{g,n,d}$ be the moduli stack of degree-$d$ stable maps to $X$ from genus-$g$ curves with $n$ marked points [10]. Gromov–Witten invariants of $X$ are intersection numbers in $X_{g,n,d}$ against the virtual fundamental cycle $[X_{g,n,d}]^\text{vir}$ [2, 11]. Let $Y \subset X$ be a complete intersection cut out by a section of a vector bundle $E \to X$ which is the direct sum of line bundles $E = \oplus E_j$. The inclusion $i : Y \to X$ induces a morphism of moduli stacks $\iota : Y_{g,n,\delta} \to X_{g,n,i,\delta}$. Suppose that the line bundles $E_j$ each satisfy the positivity condition:

d \geq 0 \quad \text{whenever } d

Then:

\[ \sum_{\delta : \iota^* \delta = d} \iota_* [Y_{0,n,\delta}]^\text{vir} = [X_{0,n,d}]^\text{vir} \cap e \]

where $e$ is the Euler class and $E_{0,n,d}$ is a certain vector bundle on $X_{0,n,d}$, described in [5] below. Equality (†) lies at the heart of the Quantum Lefschetz Hyperplane Principle, and hence of the proof of mirror symmetry for toric complete intersections [6, 7, 12–14]. (See [5] for a very clear explanation of this.)

In this paper we show by means of examples that, for orbifold complete intersections, (†) does not imply (†). We give examples of smooth orbifolds $X$ and complete intersections $Y \subset X$ cut out by sections of vector bundles $E = \oplus E_j \to X$ such that each $E_j$ is a line bundle that satisfies (†) but there is no cohomology class $e$ on $X_{0,n,d}$ with:

\[ \sum_{\delta : \iota^* \delta = d} \iota_* [Y_{0,n,\delta}]^\text{vir} = [X_{0,n,d}]^\text{vir} \cap e \]

In particular there is no vector bundle $E_{0,n,d}$ on $X_{0,n,d}$ such that (†) holds. Thus the Quantum Lefschetz Hyperplane Principle, as currently understood, can fail for positive orbifold complete intersections.

2010 Mathematics Subject Classification. Primary 14N35; Secondary 14A20.

Key words and phrases. Gromov–Witten invariants, orbifolds, quantum cohomology, hypersurfaces, complete intersections, Quantum Lefschetz Hyperplane Theorem.

Remark 1.1. There does not seem to be a universally-accepted definition of ampleness for line bundles on orbifolds (see [20, §2.5] for one possibility) but any reasonable definition will imply property (*).

2. Genus-one Gromov–Witten invariants of the quintic 3-fold

It is well-known that there is no straightforward analog of the Quantum Lefschetz Hyperplane Principle for higher-genus stable maps (those with $g > 0$), even when both $X$ and $Y$ are smooth varieties. Givental gave an example that demonstrates this [8]; for the convenience of the reader we repeat his argument here. Recall that for any smooth projective variety $X$, the moduli stack $X_{1,1,0}$ of degree-zero one-pointed stable maps from genus-one curves to $X$ is isomorphic to $X \times \overline{M}_{1,1}$. Let $\pi_1 : X_{1,1,0} \to X$ denote projection to the first factor, $\pi_2 : X_{1,1,0} \to \overline{M}_{1,1}$ denote projection to the second factor, and $\psi_1 \in H^2(\overline{M}_{1,1})$ denote the universal cotangent line class. The virtual fundamental class is:

$$[X_{1,1,0}]^{\text{vir}} = [X_{1,1,0}] \cap \left( \pi_1^*(c_D(TX)) - \pi_1^*(c_{D-1}(TX)) \right) \cup \pi_2^*(\psi_1)$$

where $D$ is the complex dimension of $X$.

Now let $X = \mathbb{P}^4$ and $Y \subset X$ be a quintic threefold, i.e. $Y$ is the hypersurface cut out by a generic section of $E = \mathcal{O}(5) \to X$. As before, let $i : Y \to X$ be the inclusion and $\iota : Y_{1,1,0} \to X_{1,1,0}$ be the induced map of moduli stacks. We will show that there is no cohomology class $e$ on $X_{1,1,0}$ such that:

$$\iota_* [Y_{1,1,0}]^{\text{vir}} = [X_{1,1,0}]^{\text{vir}} \cap e$$

Since both $[Y_{1,1,0}]^{\text{vir}}$ and $[X_{1,1,0}]^{\text{vir}}$ have the same dimension, this amounts to showing that $\iota_* [Y_{1,1,0}]^{\text{vir}}$ is not a scalar multiple of $[X_{1,1,0}]^{\text{vir}}$.

Let $h \in H^2(X)$ denote the first Chern class of the line bundle $\mathcal{O}(1)$ on $X$. Applying the total Chern class to both sides of the equality:

$$TY \oplus i^* \mathcal{O}(5) = i^* TX$$

yields $c_1(TY) = 0$, $c_2(TY) = 10i^*(h^2)$, $c_3(TY) = -40i^*(h^3)$. Thus:

$$\iota_* [Y_{1,1,0}]^{\text{vir}} = \iota_* (-40i^*(h^3) - 10i^*(h^2)\psi_1) = (-40h^3 - 10h^2\psi_1) \cup \iota_* 1 = -200h^4 - 50h^3\psi_1$$

where in the second line we used the projection formula and in the last line we used the fact that the normal bundle to the inclusion $\iota$ is $\pi_1^* \mathcal{O}(5)$. On the other hand:

$$[X_{1,1,0}]^{\text{vir}} = 5h^4 - 10h^3\psi_1$$

and so $\iota_* [Y_{1,1,0}]^{\text{vir}}$ is not a scalar multiple of $[X_{1,1,0}]^{\text{vir}}$.

3. A trivial example

Let $X$ be the orbifold $\mathbb{P}(1, 1, 2, 2)$, and let $Y = \mathbb{P}(1, 2, 2)$ be the orbifold hypersurface in $X$ defined by the vanishing of a section of $\mathcal{O}(1)$. Let $X_{0,4,0}$ and $Y_{0,4,0}$ denote the moduli stacks of genus-zero degree-zero stable maps to (respectively) $X$ and $Y$, from orbicurves with four marked points such that the isotropy group at each marked point is $\mu_2$. As before, write $i : Y \to X$ for the inclusion map, and $\iota : Y_{0,4,0} \to X_{0,4,0}$ for the induced morphism of moduli stacks. We

---

1 The vector $\vec{i}$ in the subscript here is to emphasize the fact that we specify not only the number of marked points on the curves but also the isotropy group at each marked point.
have $\text{vdim} \ X_{0,4,0} = 0$ and $\text{vdim} \ Y_{0,4,0} = 1$, so for dimensional reasons there is no cohomology class $e$ on $X_{0,4,0}$ such that:

$$\iota_* [Y_{0,4,0}]^\text{vir} = [X_{0,4,0}]^\text{vir} \cap e$$

4. A NON-TRIVIAL EXAMPLE

Let $X$ be the orbifold $\mathbb{P}(1, 1, 1, 2, 2, 2)$, and let $Y = \mathbb{P}(1, 1, 2, 2, 2)$ be the orbifold complete intersection in $X$ defined by the vanishing of a section of $\mathcal{O}(1) \oplus \mathcal{O}(2)$. Let $X_{0,4,0}$ and $Y_{0,4,0}$ denote the moduli stacks of genus-zero degree-zero stable maps to (respectively) $X$ and $Y$, from orbicurves with four marked points such that the isotropy group at each marked point is $\mu_2$. Let $i : Y \to X$ be the inclusion map and $\iota : Y_{0,4,0} \to X_{0,4,0}$ be the induced morphism of moduli stacks. We have:

$$\text{vdim} \ X_{0,4,0} = 1 \quad \quad \quad \quad \quad \text{vdim} \ Y_{0,4,0} = 1$$

and the coarse moduli spaces are:

$$|X_{0,4,0}| = \mathbb{P}^3 \times \overline{\mathcal{M}}_{0,4} \quad \quad \quad |Y_{0,4,0}| = \mathbb{P}^2 \times \overline{\mathcal{M}}_{0,4}$$

where $\overline{\mathcal{M}}_{0,4}$ is Deligne–Mumford space. Recall that the rational homology and cohomology groups of a smooth stack coincide with the rational homology and cohomology groups of the coarse moduli space [1, §2]. We therefore regard all virtual fundamental classes, cohomology classes, Chern classes, etc. in our calculation as living on the coarse moduli spaces of the stacks involved.

**Proposition 4.1.** We have:

$$X_{0,4,0} = \mathbb{P}(2, 2, 2, 2) \times \overline{\mathcal{M}}_{0,4} \quad \quad \quad Y_{0,4,0} = \mathbb{P}(2, 2, 2) \times \overline{\mathcal{M}}_{0,4}$$

**Proof.** We prove the proposition only for $X_{0,4,0}$: the argument for $Y_{0,4,0}$ is almost identical. The moduli stack $X_{0,4,0}$ is a $\mu_2$-gerbe over the coarse moduli space $|X_{0,4,0}|$. Such gerbes necessarily have trivial lien[2], and thus are classified by the sheaf cohomology group:

$$H^2(|X_{0,4,0}|, \mu_2) \cong H^2(\mathbb{P}^3, \mu_2) \times H^2(\overline{\mathcal{M}}_{0,4}, \mu_2)$$

$$\cong \mu_2 \times \mu_2$$

The gerbe $\mathbb{P}(2, 2, 2, 2) \times \overline{\mathcal{M}}_{0,4}$ over $\mathbb{P}^3 \times \overline{\mathcal{M}}_{0,4}$ is non-trivial on the first factor and trivial on the second factor, and therefore corresponds to the class $(-1, 1) \in \mu_2 \times \mu_2$. It thus suffices to show that the gerbe $X_{0,4,0}$ over $\mathbb{P}^3 \times \overline{\mathcal{M}}_{0,4}$ also corresponds to the class $(-1, 1) \in \mu_2 \times \mu_2$.

Let $\pi_1$ and $\pi_2$ denote the projections to (respectively) the first and second factors of the product $\mathbb{P}^3 \times \overline{\mathcal{M}}_{0,4}$. There is a commutative diagram:

$$\begin{array}{ccc}
\mathbb{P}(2, 2, 2, 2) & \xleftarrow{\Phi} & X_{0,4,0} \\
\downarrow & & \downarrow \\
\mathbb{P}^3 & \xleftarrow{\pi_1} & \mathbb{P}^3 \times \overline{\mathcal{M}}_{0,4}
\end{array}$$

where each vertical arrow is the canonical map from a stack to its coarse moduli space, and $\Phi$ is the natural morphism coming from the fact that $X_{0,4,0}$ is a moduli stack of degree-zero maps. This implies that restricting the gerbe $X_{0,4,0}$ over $\mathbb{P}^3 \times \overline{\mathcal{M}}_{0,4}$ to a fiber of $\pi_2$ yields the non-trivial gerbe $\mathbb{P}(2, 2, 2, 2)$ over $\mathbb{P}^3$. On the other hand, restricting the gerbe $X_{0,4,0}$ over $\mathbb{P}^3 \times \overline{\mathcal{M}}_{0,4}$ to a fiber of $\pi_1$ yields the trivial

---

[2] The lien of a gerbe is also known as its band. For a careful discussion of bands and the classification of gerbes, see [15] Lecture 3.
gerbe \((B\mu_2)_{0,\hat{4},0}\) over \(\overline{M}_{0,4}\). Thus the gerbe \(X_{0,\hat{4},0}\) over \(\mathbb{P}^3 \times \overline{M}_{0,4}\) corresponds to the class \((-1, 1) \in \mu_2 \times \mu_2\). The Proposition is proved. \(\square\)

We will show that there is no cohomology class \(e\) on \(X_{0,\hat{4},0}\) such that:

\[
\iota_* [Y_{0,\hat{4},0}]^\text{vir} = [X_{0,\hat{4},0}]^\text{vir} \cap e
\]

As before, this amounts to showing that \(\iota_* [Y_{0,\hat{4},0}]^\text{vir}\) and \([X_{0,\hat{4},0}]^\text{vir}\) are not scalar multiples of each other. Consider the universal families over the moduli stacks \(X_{0,\hat{4},0}\) and \(Y_{0,\hat{4},0}\):

The moduli stack \(X_{0,\hat{4},0}\) is smooth, with obstruction bundle \(V\oplus 3\) where:

\[
V = R^1\pi_* (\ev^* \mathcal{O}_X(1))
\]

Thus the virtual fundamental class of \(X_{0,\hat{4},0}\) is:

\[
(4.2) \quad [X_{0,\hat{4},0}]^\text{vir} = [X_{0,\hat{4},0}] \cap e(V)^3
\]

The moduli stack \(Y_{0,\hat{4},0}\) is also smooth, with obstruction bundle:

\[
\left[R^1\pi_* (\ev^* \mathcal{O}_Y(1))\right]^{\oplus 2}
\]

and since the universal family over \(Y_{0,\hat{4},0}\) is the restriction to \(Y_{0,\hat{4},0}\) of the universal family over \(X_{0,\hat{4},0}\):

it follows that:

\[
\left[R^1\pi_* (\ev^* \mathcal{O}_Y(1))\right]^{\oplus 2} = \iota^* V^{\oplus 2}
\]

Thus the virtual fundamental class of \(Y_{0,\hat{4},0}\) is:

\[
(4.3) \quad [Y_{0,\hat{4},0}]^\text{vir} = [Y_{0,\hat{4},0}] \cap e(\iota^* V)^2
\]

We next identify the Euler class of \(V\). As before, let \(\pi_1\) and \(\pi_2\) denote the projections to (respectively) the first and second factors of the coarse moduli space \(|X_{0,\hat{4},0}| = \mathbb{P}^3 \times \overline{M}_{0,4}\). Let \(h \in H^2(|X_{0,\hat{4},0}|)\) be the pullback along \(\pi_1\) of the first Chern class of the line bundle \(\mathcal{O}(1) \to \mathbb{P}^3\). Let \(\psi \in H^2(|X_{0,\hat{4},0}|)\) be the pullback along \(\pi_2\) of the universal cotangent line class on \(\overline{M}_{0,4}\) corresponding to the first marked point. Note that \(\{h, \psi\}\) forms a basis for \(H^2(|X_{0,\hat{4},0}|)\).
We saw in the proof of Proposition 4.1 that restricting the gerbe (4.4)

\[ C_X \xrightarrow{\pi} X \]

and recall that \( X_{0, \mathcal{I}, 0} \equiv \mathbb{P}(2, 2, 2, 2) \times \mathcal{M}_{0, 4} \). We have:

\[ \mathcal{V} = -\pi_* \pi^*(\mathcal{O}_X(1)) \quad \text{(K-theory pushforward)} \]

\[ = -\pi_* \pi^*(\mathcal{O}_{\mathbb{P}(2, 2, 2, 2)}(1)) \]

\[ = \mathcal{O}_{\mathbb{P}(2, 2, 2, 2)}(1) \boxtimes (-\pi_* \mathcal{O}_{C_X}) \quad \text{(projection formula)} \]

We saw in the proof of Proposition 4.1 that restricting the gerbe \( X_{0, \mathcal{I}, 0} \) over \( \mathbb{P}^3 \times \mathcal{M}_{0, 4} \) to a fiber of \( \pi_2 \) yields \( \mathbb{P}(2, 2, 2, 2) \). The restriction of \( \mathcal{V} \) to this copy of \( \mathbb{P}(2, 2, 2, 2) \) is \( \mathcal{O}_{\mathbb{P}(2, 2, 2, 2)}(1) \), and so:

\[ e(\mathcal{V}) = \frac{1}{4} h + \alpha \psi \]

for some scalar \( \alpha \). We saw in the proof of Proposition 4.1 that restricting the gerbe \( X_{0, \mathcal{I}, 0} \) over \( \mathbb{P}^3 \times \mathcal{M}_{0, 4} \) to a fiber of \( \pi_1 \) yields \( (B \mu_2)_{0, \mathcal{I}, 0} \). The restriction of \( \mathcal{V} \) to this copy of \( (B \mu_2)_{0, \mathcal{I}, 0} \) is \( \mathcal{E}^\vee \), where \( \mathcal{E} \) is the Hodge bundle on \( (B \mu_2)_{0, \mathcal{I}, 0} \), and so we can determine the scalar \( \alpha \) by comparing the integrals:

\[ \int_{(B \mu_2)_{0, \mathcal{I}, 0}} c_1(\mathcal{E}) = \frac{1}{4} \]

\[ \int_{\mathcal{M}_{0, 4}} \psi_1 = 1 \]

The right-hand integral here is well-known; the left-hand integral is computed in [15, §3.1].

**Proposition 4.3.** The classes \( \iota_* [Y_{0, \mathcal{I}, 0}]^{\text{vir}} \) and \( [X_{0, \mathcal{I}, 0}]^{\text{vir}} \) are not scalar multiples of each other.

**Proof.** Combining (4.2) and (4.3) with Lemma 4.2 we have:

\[ [X_{0, \mathcal{I}, 0}]^{\text{vir}} = [X_{0, \mathcal{I}, 0}] \cap \left( \frac{1}{4} h^3 - \frac{3}{4} h^2 \psi \right) \]

and:

\[ \iota_* [Y_{0, \mathcal{I}, 0}]^{\text{vir}} = \iota_* [Y_{0, \mathcal{I}, 0}] \cap e(\mathcal{V})^2 \]

\[ = [X_{0, \mathcal{I}, 0}] \cap \left( h \cup \frac{1}{4} (h - \psi)^2 \right) \]

\[ = [X_{0, \mathcal{I}, 0}] \cap \left( \frac{1}{4} h^3 - \frac{1}{2} h^2 \psi \right) \]

Since \( h^3 \) and \( h^2 \psi \) are linearly independent in \( H^6([X_{0, \mathcal{I}, 0}]) \), the Proposition follows. \( \square \)

5. Convexity

Our examples show that the key property underlying (1) is not positivity (\( \ast \)) of \( E \) but rather convexity of \( E \). Recall that a vector bundle \( E \to X \) is called convex if and only if \( H^1(C, f^* E) = 0 \) for all stable maps \( f : C \to E \) from genus-zero (orbi)curves. Suppose that \( E = \bigoplus E_j \) is a direct sum of line bundles and that each line bundle \( E_j \) satisfies (\( \ast \)). If \( X \) is a smooth variety then \( E \) is automatically convex but, as we will discuss below, this need not be the case if \( X \) is an orbifold.
Let \( X \) be a smooth projective variety or smooth orbifold, and let \( E \to X \) be a convex vector bundle. Let:

\[
\begin{array}{c}
C \xrightarrow{\pi} X \\
\downarrow \\
X_{0,n,d}
\end{array}
\]

be the universal family over the moduli stack \( X_{0,n,d} \) of genus-zero stable maps and let \( E_{0,n,d} = R^0 \pi_* ev^* E \). Convexity implies that \( R^1 \pi_* ev^* E = 0 \), and hence that \( E_{0,n,d} \) is a vector bundle on \( X_{0,n,d} \).

**Proposition 5.1** (Convexity implies \((\dagger)\)). Let \( X \) be a smooth projective variety or orbifold, let \( E \to X \) be a convex vector bundle, and let \( Y \) be the subvariety or suborbifold of \( X \) cut out by a generic section \( s \) of \( E \). Let \( i : Y \to X \) be the inclusion map, and let \( \iota : Y_{0,n,\delta} \to X_{0,n,\iota,\delta} \) be the induced morphism of moduli stacks. Then:

\[
\sum_{\delta, \iota, \delta = d} \iota_* [Y_{0,n,\delta}]^{\text{vir}} = [X_{0,n,d}]^{\text{vir}} \cap e(E_{0,n,d})
\]

**Proof.** The stacks \( X_{0,n,d} \) and \( Y_{0,n,\delta} \) carry perfect obstruction theories relative to the Artin stack \( \mathfrak{M} \) of marked twisted curves [1]:

\[
(\mathcal{R}^* \pi_* ev^* T_X)^\vee \quad \text{for} \quad X_{0,n,d}
\]

\[
(\mathcal{R}^* \pi_* ev^* T_Y)^\vee \quad \text{for} \quad Y_{0,n,\delta}
\]

Write:

\[
Y_d = \coprod_{\delta, \iota, \delta = d} Y_{0,n,\delta}
\]

and consider the 2-Cartesian diagram of Deligne–Mumford stacks:

\[
\begin{array}{c}
Y_d \xrightarrow{i} X_{0,n,d} \\
\downarrow \\
X_{0,n,d}
\end{array}
\]

where 0 is the zero section of \( E_{0,n,d} \) and \( \tilde{s} \) is the section of \( E_{0,n,d} \) induced by \( s \). For a morphism \( A \to B \) of stacks, let \( L_{A/B} \) denote the relative cotangent complex [17]. There is a morphism of distinguished triangles in the derived category of sheaves on \( Y_d \):

\[
\begin{array}{c}
t^*(\mathcal{R} \pi_* ev^* T_X)^\vee \to (\mathcal{R} \pi_* ev^* T_Y)^\vee \to t^* E_{0,n,d}^{\vee}[1] \\
\downarrow \\
t^* L_{X_{0,n,d}/\mathfrak{M}} \to L_{Y_d/\mathfrak{M}} \to L_{Y_d/X_{0,n,d}} \\
\downarrow \\
t^* L_{X_{0,n,d}/\mathfrak{M}}[1]
\end{array}
\]

and, since \( E \) is convex, we have:

\[
t^* E_{0,n,d}^{\vee}[1] = t^* L_{X_{0,n,d}/E_{0,n,d}}
\]

Thus the perfect obstruction theories \((5.1)\) are compatible over \( i : Y_d \to X_{0,n,d} \) in the sense of Behrend–Fantechi [2 Definition 5.8]. Functoriality for the virtual fundamental class [16] now implies that:

\[
0^! [X_{0,n,d}]^{\text{vir}} = \sum_{\delta, \iota, \delta = d} [Y_{0,n,\delta}]^{\text{vir}}
\]

The Proposition follows. \(\square\)
Remark 5.2. In the non-convex case, much of this goes through but the perfect obstruction theories involved are no longer compatible along $\iota$.

Remark 5.3. Suppose now that $X$ is a smooth orbifold and that $E \to X$ is a line bundle on $X$ that satisfies (+). A straightforward argument involving orbifold Riemann–Roch [4, §7] shows that $E$ is convex if and only if $E$ is the pullback of a line bundle on the coarse moduli space of $X$.

6. Conclusion

We have seen that the Quantum Lefschetz Hyperplane Principle can fail for orbifold complete intersections, in cases where the bundle defining the complete intersection is non-convex. Thus at the moment we lack tools to prove mirror theorems for such complete intersections, even when the ambient orbifold is toric. A positivity condition alone (+) is not enough to force convexity: it is necessary also for the bundle involved to be the pullback of a bundle on the coarse moduli space. This latter condition is very restrictive, and so “most” bundles on orbifolds are not convex.

Despite the examples in this paper one may still hope that, under some mild conditions, genus-zero Gromov–Witten invariants of orbifold complete intersections coincide with appropriate twisted Gromov–Witten invariants. For example, the equivariant-Euler twisted $I$-function $I^{tw}(t, z)$ in [4, Theorem 4.8] admits a non-equivariant limit when the bundle $E$ and the parameter $t$ involved satisfy certain mild conditions [4, Corollary 5.1]. This is surprising, because the conditions there do not imply convexity. So one can hope that the twisted $I$-function still calculates the genuine invariants in such cases. (In the examples in this paper, the relevant twisted $I$-function does not admit a non-equivariant limit.) For example, Guest–Sakai computed the small quantum cohomology of a degree 3 hypersurface in $P(1,1,1,2)$ from the differential equation satisfied by the twisted $I$-function [6], showing that the result coincides with Corti’s geometric calculation.

Establishing the relationship between Gromov–Witten invariants of orbifold complete intersections and twisted Gromov–Witten invariants will require new methods. In the case of positive, non-convex bundles on orbifolds, the geometry involved is very similar to that which occurs when studying higher-genus stable maps to hypersurfaces in smooth varieties. Zinger and his coauthors [18,21] and Chang–Li [3] have made significant progress in this area recently, and it will be interesting to see if their techniques shed light on the genus-zero orbifold case too.
