Abstract. We provide new characterizations of two previously studied questions on nondeterministic function classes:

Q1: Do nondeterministic functions admit efficient deterministic refinements?
Q2: Do nondeterministic function classes contain complete functions?

We show that Q1 for the class \( \text{NPMV}_t \) is equivalent to the question whether the standard proof system for SAT is p-optimal, and to the assumption that every optimal proof system is p-optimal. Assuming only the existence of a p-optimal proof system for SAT, we show that every set with an optimal proof system has a p-optimal proof system. Under the latter assumption, we also obtain a positive answer to Q2 for the class \( \text{NPMV}_t \).

An alternative view on nondeterministic functions is provided by disjoint sets and tuples. We pursue this approach for disjoint \( \text{NP} \)-pairs and its generalizations to tuples of sets from \( \text{NP} \) and \( \text{coNP} \) with disjointness conditions of varying strength. In this way, we obtain new characterizations of Q2 for the class \( \text{NPSV} \).

Question Q1 for \( \text{NPSV} \) is equivalent to the question whether every disjoint \( \text{NP} \)-pair is easy to separate. In addition, we characterize this problem by the question whether every propositional proof system has the effective interpolation property. Again, these interpolation properties are intimately connected to disjoint \( \text{NP} \)-pairs, and we show how different interpolation properties can be modeled by \( \text{NP} \)-pairs associated with the underlying proof system.

1 Introduction

Most computational tasks are naturally formulated as functional problems, i.e., for a given input a solution to the problem instance has to be computed. Quite in contrast, computational complexity theory mainly studies language problems and their associated complexity classes. Of course, by studying the undergraph \( \{ \langle x, y \rangle \mid y \leq f(x) \} \) of a function \( f \), every functional problem can be transformed into a corresponding decision version, which justifies the focus on language complexity. On the other hand, some computational phenomena are most naturally addressed in the functional setting, and this particularly applies to nondeterministic functions (cf. [54] for a beautiful argument on this theme).

Prominent questions in the functional context are in particular:

* Part of the results of this paper appeared in an extended abstract in the proceedings of the conference FSTTCS 2000 [27]. This work was done while the first author was at Humboldt University Berlin and the third author was at Ulm University. Research was partially supported by DFG grant KO 1053/5-1.
Q1: Do nondeterministic functions possess efficient deterministic refinements?
Q2: Do nondeterministic function classes possess complete functions?

During the last decade these problems have been intensively studied for a variety of function classes (cf. [53] for a comprehensive taxonomy or [23, 29] for equivalent characterizations). Question Q1 is important in connection with cryptographic applications, as Q1 (for the function class $NPMV_t$) is equivalent to the question whether all polynomial-time computable onto honest functions are invertible in polynomial time. The question was further characterized by Fenner, Fortnow, Naik, and Rogers [14] by a number of previously studied complexity-theoretic assumptions, and they named the list of these equivalences as “Q” (cf. also [16]). Determining the precise strength of Q seems to be intricate. On the one hand, Q has unlikely collapse consequences such as $P = NP \cap \text{coNP}$. On the other hand, Q does not seem as strong as to imply a collapse of the polynomial hierarchy [10].

In this paper we will argue that the above two questions on function classes are closely connected to disjoint $\text{NP}$-pairs and their generalizations, as well as to problems about proof systems. Disjoint $\text{NP}$-pairs have recently been intensively studied [42, 17–21, 49, 5, 3, 4], mainly, because they are suitable objects to model the security of cryptosystems [22, 33], and further, because they are intimately connected to propositional proof systems [45, 42, 19, 21, 3].

Nondeterministic functions were already linked to disjoint $\text{coNP}$-pairs by Fenner et al. [14]. Here we will extend this connection to further function classes and disjoint $\text{NP}$-pairs as well as tuples of disjoint $\text{NP}$-sets (cf. [5]) and disjoint $\text{coNP}$-pairs. This correspondence provides an alternative view on disjoint $\text{NP}$-pairs and allows elegant characterizations of Questions Q1 and Q2 above. Namely, Q1 is equivalent to the statement that every disjoint $\text{NP}$-pair is easy to separate, while Q2 is equivalent to the problem, whether the class of disjoint $\text{NP}$-pairs (and its generalizations) possess complete elements. In the context of $\text{NP}$-pairs, this question was posed by Razborov [45], and it has been intensively studied during the last years [17, 18, 5, 3, 4]. Our characterizations restate and unify some of these recent results in terms of nondeterministic functions.

Another important connection of nondeterministic functions (and equivalently of disjoint sets) is to the field of proof systems, as introduced for arbitrary languages by Cook and Reckhow [11]. We will show that in this setting, Question Q1 (for functions from $\text{NPSV}$) can be restated as the question, whether all propositional proof systems satisfy the effective interpolation property (cf. [31, 33]). This again is equivalent to the statement that every disjoint $\text{NP}$-pair is $\text{P/poly}$-separable, which in turn implies that $\text{NP} \cap \text{coNP} \subseteq \text{P/poly}$ and $\text{UP} \subseteq \text{P/poly}$.

Similarly, we also provide another characterization of Q (or equivalently, Question Q1 for functions from $\text{NPMV}_t$). Namely, we investigate the problem, whether the standard proof system $\text{sat}$ for $\text{SAT}$ is $\text{p}$-optimal\(^4\), where proofs in $\text{sat}$ are given by a satisfying assignment for the formula in question. We show that this question is equivalent to the assertion Q, and it is further characterized

\(^4\) Pavel Pudlák posed this question during the discussion after Zenon Sadowski’s talk at CSL’98 [47]
by the statement that the two common notions of reductions between proof systems, i.e., simulations [32] and p-simulations [11], coincide. Thus Q is also equivalent to the statement that every optimal proof system is p-optimal. Under the weaker assumption of the mere existence of a p-optimal proof system for SAT we can still show that every language with an optimal proof system also has a (possibly different) p-optimal proof system.

The (likely) assumption that there are no p-optimal proof systems for SAT (as well as for TAUT) also has some practical implications due to its connection to the existence of optimal algorithms (cf. [32, 48, 49, 36]). Note that usually a decision algorithm for SAT also provides a satisfying assignment for any positive instance. However, if sat is not p-optimal, then no decision algorithm for SAT that produces satisfying assignments for positive instances can be optimal (cf. Theorem 16). In fact, a stronger consequence can be derived: if sat is not p-optimal, then there is a non-sparse set of easy instances from SAT for which it is hard to produce a satisfying assignment (cf. Theorem 20).

It has been observed in [46, 28] that (p-)optimal proof systems for certain languages can be used to define complete sets for certain promise classes. For example, if TAUT has an optimal proof system, then \( \text{NP} \cap \text{Sparse} \) has a many-one complete set, and if TAUT as well as SAT have a p-optimal proof system, then \( \text{NP} \cap \text{coNP} \) has a complete set. We complete this picture here by showing that already a p-optimal proof system for SAT can be used to derive completeness consequences.

In particular, we prove that a p-optimal proof system for SAT implies complete functions for \( \text{NPMV}_t \) (which in turn implies complete disjoint \( \text{coNP} \)-pairs). Further, the existence of an optimal proof system for TAUT implies the existence of complete functions for \( \text{NPkV} \) (or equivalently, complete tuples of \( \text{NP} \)-sets with some disjointness conditions). And finally, the existence of optimal proof systems for TAUT and p-optimal proof systems for SAT implies the existence of complete functions for \( \text{NPSV}_t \) (or equivalently, complete sets for \( \text{NP} \cap \text{coNP} \)).

Overview of the Paper

This paper is organized as follows. After fixing notation and reviewing relevant definitions about function classes, proof systems, and disjoint tuples (Sect. 2), we start in Sect. 3 by exploring the connections between nondeterministic functions and pairs (as well as tuples) of disjoint sets. Particular attention is directed towards the problem of the existence of complete functions and pairs for the respective classes (Question Q2 above).

Section 4 is devoted to Question Q1 above, i.e., whether functions from \( \text{NPSV} \) possess total refinements in \( \text{FP} \) or \( \text{FP}/\text{poly} \). It turns out that this questions is intimately connected to different interpolation properties of propositional proof systems, and we characterize these interpolation properties by disjoint \( \text{NP} \)-pairs, associated with the proof system.

In Sect. 5 we investigate whether the standard proof system sat for SAT is p-optimal. We show this question to be equivalent to the assertion Q from [14] (and hence to Question Q1 for \( \text{NPMV}_t \)). In addition we provide several
new characterizations of this problem in terms of simulations and optimal algorithms.

Finally, in Sect. 6 we analyse the weaker question whether there exists a p-optimal proof system for SAT. We show that this is equivalent to the statement that every language with an optimal proof system also has a p-optimal proof system, and derive some collapse consequences from these assumptions.

2 Preliminaries and Notation

Let $\Sigma = \{0, 1\}$. We denote the cardinality of a set $A$ by $|A|$ and the length of a string $x \in \Sigma^*$ by $|x|$. The empty word is denoted by $\lambda$. FP is the class of (partial) functions that can be computed in polynomial time. A set $S$ is called sparse if the cardinality of $S \cap \Sigma^n$ is bounded above by a polynomial in $n$. $S$ is called printable if there exists a function in FP which on input 1$^n$ outputs all elements in $S$ of length $n$. We use $\langle \cdot, \ldots, \cdot \rangle$ to denote a standard polynomial-time computable tupling function. For the definitions of standard complexity classes like $P$, $NP$ etc. we refer to the monographs [2] and [39].

A function $h$ is called FP-invertible if there is a function $f \in$ FP that inverts $h$, i.e., $h(f(y)) = y$ for each $y$ in the range of $h$. A function $h$ is honest if for some polynomial $p$, $p(|h(x)|) \geq |x|$ holds for all $x$ in the domain of $h$. We call a function $g$ an extension of a function $f$ if $f(x) = g(x)$ for any $x$ in the domain of $f$. A function $r : \mathbb{N} \to \mathbb{N}$ is called super-polynomial if for each polynomial $p$, $r(n) > p(n)$ for almost every $n \geq 0$. A set $B \in P$ with $B \subseteq L$ is called a $P$-subset of $L$.

2.1 Nondeterministic Function Classes

A nondeterministic polynomial-time Turing machine (NPTM, for short) is a Turing machine $N$ such that for some polynomial $p$, every accepting path of $N$ on any input of length $n$ is at most of length $p(n)$. A nondeterministic transducer is a nondeterministic Turing machine $T$ with a write-only output tape. On input $x$, $T$ outputs $y \in \Sigma^*$ (in symbols: $T(x) \rightarrow y$) if there is an accepting path on input $x$ along which $y$ is written on the output tape. Hence, the function $f$ computed by $T$ on $\Sigma^*$ could be multi-valued and partial. Using the notation of [9, 53] we denote the set $\{y \mid f(x) \rightarrow y\}$ of all output values of $T$ on input $x$ by set-$f(x)$.

The class of all multi-valued, partial functions computable by some nondeterministic polynomial-time transducer $T$ is denoted by NPMV. But also various subclasses of NPMV are of interest. NPSV is the class of functions $f$ in NPMV that are single-valued, i.e., $|\text{set}-f(x)| \leq 1$. Thus, the functions from NPSV are functions in the usual sense, and we use $f(x)$ to denote the unique string in set-$f(x)$. Relaxing the condition $|\text{set}-f(x)| \leq 1$ by allowing $|\text{set}-f(x)| \leq k$ for some fixed number $k \geq 1$ leads to the classes NPKV, defined in [38, 14]. Even more generally, Fenner, Fortnow, Naik, and Rogers [14] considered functions $f$ where the cardinality of set-$f(x)$ is bounded by a function $g(x)$ rather than a constant. For a function $g$, this function class is denoted by NPgV.
The domain of a multi-valued function is the set of those inputs $x$ where \(\text{set-f}(x) \neq \emptyset\). A function is called total if its domain is \(\Sigma^*\). For a function class \(\mathcal{F}\) we denote by \(\mathcal{F}_t\) the class of total functions in \(\mathcal{F}\). We use \(\mathcal{F}_t \subseteq \text{FP}\) to indicate that for any \(g \in \mathcal{F}_t\) there is a total function \(f \in \text{FP}\) that is a refinement of \(g\), i.e., \(f(x) \in \text{set-g}(x)\) for all \(x \in \Sigma^*\). Occasionally it is useful to explicitly indicate the range of a multi-valued function in the notation. To do this we collect in the class \(\mathcal{F}_A\) all functions from \(\mathcal{F}\) which range over subsets of \(A \subseteq \Sigma^*\), i.e., \(\text{set-f}(x) \subseteq A\) for all \(x \in \Sigma^*\).

Reductions for nondeterministic functions can be considered from a whole spectrum of reductions, ranging from many-one to Turing reductions. We start with a rather strong notion of many-one reducibility:

**Definition 1.** A multi-valued function \(h\) many-one reduces to a multi-valued function \(g\) (denoted by \(h \leq^m \text{p} \ g\)), if there is a function \(f \in \text{FP}\) such that for every \(x \in \Sigma^*\) \(\text{set-g}(f(x)) = \text{set-h}(x)\).

On the other side of the spectrum we use Turing reductions of which different versions are considered in the literature (cf. [15, 50, 53]). An oracle Turing transducer \(M\) may access a single-valued function oracle \(g\) by repeatedly querying function values. On such a query \(x\), the oracle returns the unique value from \(\text{set-g}(x)\) if \(x\) is in the domain of \(g\), otherwise \(M\) stops without any output. Using this machine model, we define Turing reductions:

**Definition 2.** A multi-valued function \(h\) Turing reduces to a multi-valued function \(g\), if there is a deterministic oracle transducer \(M\) such that for each single-valued refinement \(g'\) of \(g\), \(M^{g'}\) computes a single-valued refinement of \(h\).

In between these two kinds of reducibilities, it is natural to consider other variants of many-one reductions, for example, by allowing post-computations (cf. [34, 56]). As we will formulate most of our results in the strongest possible way (by using Turing reductions in hypotheses and many-one reductions in conclusions), they also apply to intermediate reducibilities.

### 2.2 Proof Systems

Cook and Reckhow [11] defined the notion of an abstract *proof system* for a set \(L \subseteq \Sigma^*\) as a (possibly partial) polynomial-time computable function \(h : \Sigma^* \rightarrow \Sigma^*\) with range \(L\). In this setting, an \(h\)-proof for the membership of \(\varphi\) to \(L\) is given by a string \(w\) with \(h(w) = \varphi\). We use the notation \(h \vdash \leq_m \varphi\) to indicate that there exists an \(h\)-proof of \(\varphi\) of size \(\leq m\). Proof systems for the set of all tautologies \(\text{TAUT}\) are called *propositional proof systems*.

To compare the relative strength of different proof systems, Cook and Reckhow [11] introduced the notion of \(p\)-simulation. A proof system \(h\) \(p\)-simulates a proof system \(g\) if \(g\)-proofs can be translated into \(h\)-proofs in polynomial time, i.e., there is a polynomial-time computable function \(f\) such that for each \(v\) in the domain of \(g\), \(h(f(v)) = g(v)\). Similarly, \(h\) is said to simulate \(g\) if for each \(g\)-proof \(v\) there is an \(h\)-proof \(w\) of length polynomial in the length of \(v\) with \(h(w) = g(v)\). A proof system for a set \(L\) is called \((p-)optimal\) if it \((p-)\)simulates every proof system for \(L\) (cf. [32]). It is a natural question to ask whether a set
has a p-optimal (or at least an optimal) proof system. Note that a p-optimal proof system has the advantage that from any proof in another proof system one can efficiently obtain a proof for the same instance in the p-optimal proof system. Hence, any method that is used to compute proofs in some proof system can be reformulated to yield proofs in the p-optimal proof system with little overhead.

2.3 Disjoint Pairs and Tuples

For a class \( \mathcal{C} \) of sets we call a tuple \((A_1, \ldots, A_l)\) of sets \(A_1, \ldots, A_l \in \mathcal{C}\) a disjoint \(\mathcal{C}\)-tuple if \(A_i \cap A_j = \emptyset\) for all \(1 \leq i < j \leq l\). For \(l = 2\) we just say that \((A_1, A_2)\) is a disjoint \(\mathcal{C}\)-pair, or simply a \(\mathcal{C}\)-pair. For such a disjoint pair \((A_1, A_2)\) of languages let us say that \((A_1, A_2)\) is \(D\)-separable if there is a language \(S \in D\) which separates \((A_1, A_2)\), i.e., \(A_1 \subseteq S\) and \(A_2 \cap S = \emptyset\) (cf. [22]).

Grollmann and Selman [22] introduced a notion of many-one reducibility between disjoint NP-pairs, a stronger version of which was studied in [28]. In [5] these reductions were generalized to tuples as follows. Let \((B_1, \ldots, B_l)\) and \((C_1, \ldots, C_l)\) be disjoint NP-tuples. The tuple \((B_1, \ldots, B_l)\) many-one reduces to the tuple \((C_1, \ldots, C_l)\) if there is a function \(f \in \text{FP}\) such that \(f(B_i) \subseteq C_i\) for \(i = 1, \ldots, l\). If, in addition, \(f\) also respects the complement of the union \(B_1 \cup \cdots \cup B_l\), i.e., \(f(B_1 \cup \cdots \cup B_l) \subseteq \overline{C_1} \cup \cdots \cup \overline{C_l}\), then we call the reduction strong. We denote these reductions by \(\leq_p\) and \(\leq_s\), respectively. We remark that \(f\) strongly reduces \((B_1, \ldots, B_l)\) to \((C_1, \ldots, C_l)\) if and only if \(f\) is a many-one polynomial-time reduction of \(B_i\) to \(C_i\) for each \(i \in \{1, \ldots, l\}\).

3 Nondeterministic Function Classes and Tuples of NP-Sets

There is a direct correspondence between nondeterministic functions and tuples of NP-sets, which we will explore in this section. The simplest case is provided by functions from \(\text{NPSV}_t\) and languages from \(\text{NP} \cap \text{coNP}\). With respect to this relation, Selman [53] and Hemaspaandra et al. [24] have shown that \(\text{NPSV}_t = \text{FP}^{\text{NP} \cap \text{coNP}}_t\), from which Fenner et al. [14] concluded that \(\text{NPSV}_t \subseteq \text{FP}\) holds if and only if \(P = \text{NP} \cap \text{coNP}\). We complete the picture by showing that this correspondence also extends to the question of the existence of complete problems.

**Proposition 3.** The following conditions are equivalent:

1. \(\text{NP} \cap \text{coNP}\) has a many-one complete set.
2. \(\text{NPSV}_t\) has a many-one complete function.
3. \(\text{NPSV}_t\) has a Turing complete function.

**Proof.** For the implication 1 \(\Rightarrow\) 2, assume that \(C\) is many-one complete for \(\text{NP} \cap \text{coNP}\). Hence, \(\text{NPSV}_t = \text{FP}^{\text{NP} \cap \text{coNP}}_t = \text{FP}^C_t\). But \(\text{FP}^C_t\) has a many-one complete function for any \(C\), and therefore also \(\text{NPSV}_t\) has a many-one complete function.

The implication 2 \(\Rightarrow\) 3 is immediate. For 3 \(\Rightarrow\) 1, let us assume that \(h\) is a Turing complete function for \(\text{NPSV}_t\). Since \(\text{NP} \cap \text{coNP} = \text{P}^{\text{NPSV}_t}\) it follows that \(\text{NP} \cap \text{coNP} = \text{P}^h\), and \(\text{P}^h\) has a many-one complete set for any function \(h\). \(\square\)
Now let us consider the function class $\text{NPSV}$. In the same way as $\text{NPSV}_t$ corresponds to the language class $\text{NP} \cap \text{coNP}$, the function class $\text{NPSV}$ corresponds to the class of all disjoint $\text{NP}$-pairs. In fact, if we denote the class of all $0,1$-valued functions in $\text{NPSV}$ by $\text{NPSV}_{\{0,1\}}$, then any function $h \in \text{NPSV}$ can be identified with the disjoint $\text{NP}$-pair $(D_0, D_1)$ where

$$D_b = \{ x \in \Sigma^* \mid h(x) \mapsto b \}.$$  

Generalizing this observation, for some finite set $A = \{a_1, \ldots, a_l\} \subseteq \Sigma^*$ containing $l \geq 2$ elements, the class $\text{NPSV}_A$ of all functions in $\text{NPSV}$ taking only values in $A$ corresponds to the class of all disjoint $l$-tuples of $\text{NP}$-sets, studied in [5]. If $f$ is a function from $\text{NPSV}_A$, then we can define a disjoint $l$-tuple of $\text{NP}$-sets $D_f = (D_1, \ldots, D_l)$ by $D_i = \{ x \in \Sigma^* \mid f(x) \mapsto a_i \}$. Conversely, a disjoint $l$-tuple of $\text{NP}$-sets $(D_1, \ldots, D_l)$ defines a nondeterministic function as follows. Let $M_i$ be nondeterministic polynomial-time machines that decide the sets $D_i$, respectively. The machine $M(x)$ first nondeterministically chooses an index $i \in \{1, \ldots, l\}$ and outputs the value $a_i$ if the machine $M_i(x)$ accepts. Thus $M$ computes a function $f$ from the class $\text{NPSV}_A$ such that $D_f = (D_1, \ldots, D_l)$.

This correspondence between functions from $\text{NPSV}_A$ and disjoint tuples of $\text{NP}$-sets also extends to the respective simulations, namely:

**Proposition 4.** Let $A$ be a finite subset of $\Sigma^*$, and let $f$ and $g$ be functions from $\text{NPSV}_A$. Then $f \leq_p g$ if and only if $D^f \leq_s D^g$.

Thus, for example, the class of disjoint $\text{NP}$-pairs has a strongly many-one complete pair if and only if $\text{NPSV}_{\{0,1\}}$ has a many-one complete function. As shown in the next theorem, this is even equivalent to the assumption that $\text{NPSV}$ has a many-one complete function. In addition, the theorem gives alternative and easier proofs for some results from [5] on disjoint $\text{NP}$-tuples.

**Theorem 5.** The following statements are equivalent.

1. $\text{NPSV}$ has a many-one complete function.
2. For all polynomial-time decidable sets $A \subseteq \Sigma^*$, the class $\text{NPSV}_A$ has a many-one complete function.
3. For some set $A \subseteq \Sigma^*$ with at least two elements, the class $\text{NPSV}_A$ has a many-one complete function.
4. For all numbers $l \geq 2$ there exist $\leq_s$-complete disjoint $l$-tuples of $\text{NP}$-sets.
5. For some number $l \geq 2$ there exist $\leq_s$-complete disjoint $l$-tuples of $\text{NP}$-sets.
6. There is a $\leq_s$-complete disjoint $\text{NP}$-pair.

This list can be extended by the analogous versions of items 1 to 3 where many-one reducibility is replaced by Turing reducibility.

**Proof.** To obtain the above equivalences we will verify the following implications: $1 \Rightarrow 2 \Rightarrow 4 \Rightarrow 6 \Rightarrow 5 \Rightarrow 3 \Rightarrow 1$, of which the implications $4 \Rightarrow 6 \Rightarrow 5$ are trivial, and $2 \Rightarrow 4$ as well as $5 \Rightarrow 3$ are clear by the preceding discussion on the reformulation of functions from $\text{NPSV}$ as tuples of disjoint $\text{NP}$-sets. It therefore remains to prove the implications $1 \Rightarrow 2$ and $3 \Rightarrow 1$. 

For the first of these implications let $g$ be a function many-one complete for $\text{NPSV}$ and let $A \subseteq \Sigma^*$ be decidable in polynomial time. We fix some element $a_0 \in A$ and define the function $\sigma$ as

$$\sigma(y) = \begin{cases} y & y \in A \\ a_0 & \text{otherwise.} \end{cases}$$

As $A$ is decidable in polynomial time, the function $\sigma$ is in $\text{FP}$. Then $g'(x) = \sigma(g(x))$ is a function in $\text{NPSV}_A$. Observe that for a function $h \in \text{NPSV}_A$ any many-one reduction from $h$ to $g$ also reduces $h$ to $g'$. Thus $g'$ is many-one complete for $\text{NPSV}_A$.

To prove that item 3 implies item 1, we show that $\text{NPSV}$ can be characterized as $\text{FP}^{\text{NPSV}_A}$, where the value $M^f(x)$ computed by the deterministic oracle transducer $M$ on input $x$ is only defined if all oracle queries belong to the domain of the functional oracle $f$. We first show that $\text{FP}^{\text{NPSV}_A} \subseteq \text{NPSV}$. Clearly, any function in $\text{FP}^{\text{NPSV}_A}$ is single-valued. Also a computation of $M^f$ on input $x$ where $f \in \text{NPSV}_A$ can be simulated by a nondeterministic transducer $N$ that simulates $M$, and for each query $y$ guesses an accepting path of the nondeterministic transducer that computes $f$ and answers with $f(x)$. This guarantees that $M^f(x) = N(x)$ if all oracle queries of $M^f$ on input $x$ are in the domain of $f$. If not, then by definition, $M^f(x)$ is undefined, and also set-$N(x) = \emptyset$, i.e., $N(x)$ is undefined. This shows $\text{FP}^{\text{NPSV}_A} \subseteq \text{NPSV}$.

To see that every function $f \in \text{NPSV}$ is in $\text{FP}^{\text{NPSV}_A}$, we fix two distinct elements $a_0$ and $a_1$ in $A$ and define the following function $g \in \text{NPSV}_A$:

$$g(z) = \begin{cases} a_j & \text{if } z = 1(i, x) \text{ and the } ith \text{ bit of } f(x) \text{ is } j, \\ a_0 & \text{if } z = 0(l, x) \text{ and } |f(x)| < l, \\ a_1 & \text{if } z = 0(l, x) \text{ and } |f(x)| = l. \end{cases}$$

Notice that $z$ is in the domain of $g$, if $z = 1(i, x)$ with some $x$ in the domain of $f$ and $1 \leq i \leq |f(x)|$, or if $z = 0(l, x)$ with some $x$ in the domain of $f$ and $l \leq |f(x)|$. Now an oracle transducer $M^g$ computes $f$ as follows. On input $x$, $M^g$ first determines the length $l$ of $f(x)$ by querying $0(l, x)$ for $l = 0, 1, \ldots$ until $g(0(l, x)) = a_1$ (if $x$ is not in the domain of $f$, then the first query leads to a reject of $M^g$, otherwise all the strings queried are in the domain of $g$). If $l = 0$, then $M^g$ outputs $\lambda$, otherwise the output of $M^g$ is the bit string $y_1 \cdots y_l$, where $y_i = 1$ if and only if $g(1(i, x)) = a_1$. Therefore $M^g$ computes the function $f$.

Now the assumption that there is a complete function $g$ for $\text{NPSV}_A$ implies $\text{NPSV} = \text{FP}^{\text{NPSV}_A} = \text{FP}^g$, hence also $\text{NPSV}$ has a complete function.

The additional claims in the theorem about Turing reductions follow directly from the above proof of $3 \Rightarrow 1$. Namely, assuming the existence of a Turing complete function for $\text{NPSV}_A$, the equality $\text{FP}^{\text{NPSV}_A} = \text{NPSV}$ yields the existence of many-one complete functions for $\text{NPSV}$. 

Additionally, we can get results on tuples obeying less restrictive disjointness conditions. Namely, we call a collection of sets $\{D_i\}_{i \in I}$ $k$-disjoint if $\bigcap_{i \in J} D_i = \emptyset$ for all $J \subseteq I$ such that $|J| > k$. For $k = 1$ this is just the usual pairwise
disjointness condition, but for increasing $k$ this leads to successively weaker notions. Reductions are easily generalized to this context, i.e., $f$ strongly reduces $(C_1, \ldots, C_l)$ to $(D_1, \ldots, D_l)$ if $f$ is a many-one polynomial-time reduction from the components $C_i$ to $D_i$ for $i = 1, \ldots, l$.

Similarly as above, there is a direct correspondence between $k$-disjoint $l$-tuples of NP-sets and functions from $\text{NP}^k_A$, where $\text{NP}^k_A$ denotes all functions from $\text{NP}^M$ with $\|\text{set-}f(x)\| \leq k$ and $\text{set-}f(x) \subseteq A$ for all $x \in \Sigma^*$. Then we have:

**Proposition 6.** For all numbers $l > k \geq 1$, there exist $\leq_k$-complete $k$-disjoint $l$-tuples of NP-sets if and only if $\text{NP}^k_A$ has many-one complete functions for all subsets $A \subseteq \Sigma^*$ of size $\|A\| = l$.

Similarly as in [5] we can show that the question of the existence of complete $k$-disjoint tuples does not depend on the number of components of the tuple, i.e., for all numbers $l, l' > k \geq 1$, complete $k$-disjoint $l$-tuples exist if and only if complete $k$-disjoint $l'$-tuples exist.

Instead of considering functions from $\text{NP}^k_A$, it is probably more natural to investigate the function class $\text{NP}^k$, that contains all functions from $\text{NP}^M$ such that $\|\text{set-}f(x)\| \leq k$ for all $x \in \Sigma^*$ (cf. [14, 54]). Naik, Rogers, Royer, and Selman [38] showed that with respect to refinements the classes $\text{NP}^k$, $k \geq 1$, form a strict hierarchy (called the output-multiplicity hierarchy), unless the polynomial hierarchy collapses to its second level.

Functions from $\text{NP}^k$ correspond to $k$-disjoint tuples of NP-sets where the number of components is not restricted. Analogously to the implication $1 \Rightarrow 2$ in Theorem 5 we can show the following proposition.

**Proposition 7.** If $\text{NP}^k$ contains many-one complete functions, then $\text{NP}^k_A$ contains many-one complete functions for all polynomial-time decidable sets $A \subseteq \Sigma^*$.

Fenner, Fortnow, Naik, and Rogers [14] investigated the problem whether total functions in $\text{NP}^k$ possess refinements in FP. In particular, they proved that the answer to this question is independent of $k$, i.e., if $\text{NP}^k_{t_l} \subseteq_c \text{FP}$ for some $k \geq 2$, then $\text{NP}^k_{t_l} \subseteq_c \text{FP}$ holds for all $k \geq 2$. Here we are interested in the question, whether these function classes contain complete sets. Concerning this problem we can prove:

**Theorem 8.**

1. If TAUT has an optimal proof system, then for all $k$, $\text{NP}^k$ has a many-one complete function.
2. Let $g(x)$ be a polynomial-time computable function such that for all $x \in \Sigma^*$ we have $g(x) \leq p(|x|)$ for some polynomial $p$. Then the existence of optimal proof systems for TAUT implies the existence of many-one complete functions for $\text{NP}^g$.

**Proof.** The proof follows the general method developed in [28], that amounts to bound the complexity of the promise predicates for $\text{NP}^k$ and $\text{NP}^g$. In particular, we have to show that these promise predicates are definable in $\text{coNP}$. 
For this let $N$ be an $\text{NP}$ transducer. Then the promise that $N(x)$ outputs at most $k$ different values can be defined by the formula

$$\forall y_1 \ldots \forall y_{k+1} \left( \bigwedge_{i=1}^{k+1} y_i \in \text{set-} f(x) \implies \bigvee_{1 \leq i < j \leq k+1} y_i = y_j \right), \quad (1)$$

where $f$ is the $\text{NP}_{\text{PMV}}$ function computed by $N$. As the premise $\bigwedge_{i=1}^{k+1} y_i \in \text{set-} f(x)$ defines an $\text{NP}$-predicate, the whole formula (1) is a condition in $\text{coNP}$. By choosing suitable polynomial-size nondeterministic circuits for $f$, we can translate the formula (1) to a sequence of polynomial-size propositional formulas $\theta_n^{k,f}(\bar{p}, \bar{q}, \bar{r})$, which contain propositional variables $\bar{p} = p_1, \ldots, p_n$ for the input $x$, variables $\bar{q}$ for $y_1, \ldots, y_{k+1}$, as well as auxiliary variables $\bar{r}$ for the gates of the circuits for $f$.

From the construction of $\theta_n^{k,f}$ it is clear, that $f$ is indeed a function from $\text{NP}_{\text{PV}}$ if and only if $(\theta_n^{k,f})_{n \geq 0}$ is a sequence of propositional tautologies. As for each $\text{NP}$ transducer $N$ the sequence $\theta_n^{k,f}$ can be constructed in polynomial time, we can easily define a proof system $h_f$ which admits polynomial-size proofs of the sequence $\theta_n^{k,f}$. By assumption there exists an optimal proof system $h$. As $h$ simulates all proof systems $h_f$, we have polynomial-size $h$-proofs of $\theta_n^{k,f}$ for all $f \in \text{NP}_{\text{PV}}$.

We now claim that the following function $f_k$ is complete for $\text{NP}_{\text{PV}}$: $f_k$ takes inputs of the form $\langle x, N, 0^m \rangle$. From this input, $f_k$ first computes the formula $\theta_{|x|}^{k,f}$ where $f$ is the function computed by $N$. Then $f_k$ guesses an $h$-proof $\pi$ of size $\leq m$ and verifies whether $h(\pi) = \theta_{|x|}^{k,f}$. If this is not the case, then $f_k$ stops without producing any output. Otherwise, $f_k$ simulates $N(x)$ for at most $m$ steps and gives the corresponding output. Clearly, $f_k$ belongs to $\text{NP}_{\text{PV}}$.

To verify its completeness let $N$ be an $\text{NP}$ transducer computing a function $f \in \text{NP}_{\text{PV}}$ and let $p$ be a polynomial bounding the running time of $N$ as well as the size of $h$-proofs for $\theta_n^{k,f}$. Then $f$ many-one reduces to $f_k$ via the mapping $x \mapsto \langle x, N, \theta_{|x|+|\theta_n^{k,f}|} \rangle$.

For item 2 let $g \in \text{FP}$ such that for all $x \in \Sigma^*$ we have $g(x) \leq p(|x|)$ for some polynomial $p$. Similarly as above, we define for each function $f \in \text{NP}_{\text{gV}}$ the promise of $f(x)$ with respect to $\text{NP}_{\text{gV}}$ by

$$\forall y_1 \ldots \forall y_{g(x)+1} \left( \bigwedge_{i=1}^{g(x)+1} y_i \in \text{set-} f(x) \implies \bigvee_{1 \leq i < j \leq g(x)+1} y_i = y_j \right). \quad (2)$$

By the conditions on $g$, the propositional translations of (2) have polynomial size in the length of $x$. A complete function for $\text{NP}_{\text{gV}}$ is then obtained analogously as in the proof of item 1.

Note that if $g(x)$ is a function with super-polynomial increase in $|x|$, then it is not clear whether the formulas (2) can be described by propositional formulas of size polynomial in $|x|$, and therefore the above proof method fails for such functions $g$. We also leave open, whether the reverse implications of items 1 and
2 are valid. As a more general programme, it seems interesting to determine the relationship between the assumptions of the existence of complete functions in $NP_{kV}$ and $NP_{gV}$ for different numbers $k$ and functions $g$.

We conclude this section by observing that the class of disjoint $coNP$-pairs corresponds to the class $NPbV_t$ of all 0,1-valued functions in $NPMV_t$, studied in [14]. With a disjoint $coNP$-pair $(A_0, A_1)$ we associate the function $h \in NPbV_t$ defined by set-$h(x) = \{b \mid x \notin A_b\}$.

Again, it is interesting to see what happens if we extend the range from $\{0, 1\}$ in $NPbV_t$ to arbitrary sets $A \subseteq \Sigma^*$. If $A = \{a_1, \ldots, a_k\}$ contains exactly $k$ elements, then a function $g$ from $NPMV_{t,A}$ corresponds to a tuple $(A_1, \ldots, A_k)$ of $coNP$-sets with $A_i = \{x \mid a_i \notin \text{set-}g(x)\}$. As every $x$ can be contained in at most $k-1$ sets from $A_1, \ldots, A_k$, the tuple $(A_1, \ldots, A_k)$ is $(k-1)$-disjoint (but not necessarily pairwise disjoint). Given this correspondence between $coNP$-tuples and functions from $NPMV_t$, we obtain the following result.

**Theorem 9.**

1. If $NPMV_t$ has many-one complete functions, then there exist strongly many-one complete disjoint $coNP$-pairs.
2. More generally, if $NPMV_t$ has many-one complete functions, then there exist $\leq_s$-complete $(k-1)$-disjoint $k$-tuples of $coNP$-sets for all $k \geq 2$.

**Proof.** It suffices to prove the second item. Using a similar argument as for the implication $1 \Rightarrow 2$ in Theorem 5, we can show that the existence of complete functions for $NPMV_t$ implies that for every $k \geq 2$ there exist complete functions in $NPMV_{t,A}$ for each $A \subseteq \Sigma^*$ containing exactly $k$ elements. By the above correspondence between functions from $NPMV_{t,A}$ and $(k-1)$-disjoint $k$-tuples of $coNP$-sets, we obtain the asserted complete $k$-tuple. $\Box$

We leave open whether the reverse implications also hold.

## 4 Collapse of NPSV and Effective Interpolation

In this section we investigate the question whether functions from $NPSV$ admit total extensions in $FP$ or $FP/poly$. We show that this question can be characterized by interpolation properties, which in turn are intimately connected with disjoint $NP$-pairs associated with propositional proof systems. We will start by reviewing different notions of interpolation along with their connections to disjoint $NP$-pairs.

Due to Craig’s interpolation theorem for propositional logic, for any tautology $\varphi \rightarrow \psi$ there is a formula $\theta$ that uses only common variables of $\varphi$ and $\psi$ such that $\varphi \rightarrow \theta$ and $\theta \rightarrow \psi$ are tautologies [12]. A circuit $C$ that computes the same function as $\theta$ is called an interpolant of $\varphi \rightarrow \psi$.

Lower bounds for the size of interpolants were first considered by Mundici [37], who proved that the existence of polynomial-size interpolants for all tautologies $\varphi \rightarrow \psi$ implies $NP \cap coNP \subseteq P/poly$. As the existence of polynomial-size interpolants for all tautological implications seems to be a rather strong assumption, Krajíček [31] suggested to measure the size of an interpolant not merely
in terms of the size of the implication \( \varphi \rightarrow \psi \), but in terms of the size of the shortest proof of this implication in some fixed proof system. This leads to the following definition:

**Definition 10 (Krajíček, Pudlák [33]).** A proof system \( h \) for TAUT admits effective interpolation if there is a polynomial \( p \) such that for any \( h \)-proof \( w \) of a formula \( h(w) = \varphi \rightarrow \psi \), the formula \( h(w) \) has an interpolant of size at most \( p(|w|) \).

Effective interpolation is sometimes considered in an efficient version such that it is possible to generate an interpolating circuit from an \( h \)-proof of a formula \( \varphi \rightarrow \psi \) in polynomial time. In [42] this property is called feasible interpolation.

Feasible interpolation has been shown for resolution [31], the cutting planes system [7, 31, 40], and some algebraic proof systems [43]. Combined with lower bounds for the separation of the clique colouring pair by monotone Boolean circuits [44, 1], these results yield lower bounds for the proof lengths in the above proof systems. We refer to the survey [41] for a detailed presentation of this approach.

The notion of effective interpolation for a propositional proof system \( h \) can be characterized by a disjoint \( \text{NP} \)-pair associated with the proof system \( h \). For this we define the following interpolation pair \( \text{Int}(h) \) with the components

\[
\text{Int}_1(h) = \{ \langle \varphi(\bar{x}, \bar{y}), \psi(\bar{x}, \bar{z}), \bar{a}, 0^m \rangle \mid \bar{x} \text{ are the common variables of } \varphi \text{ and } \psi, \varphi(\bar{a}, \bar{y}) \text{ is satisfiable, and } h \vdash_{\leq m} \varphi(\bar{x}, \bar{y}) \rightarrow \psi(\bar{x}, \bar{z}) \}\]

\[
\text{Int}_2(h) = \{ \langle \varphi(\bar{x}, \bar{y}), \psi(\bar{x}, \bar{z}), \bar{a}, 0^m \rangle \mid \bar{x} \text{ are the common variables of } \varphi \text{ and } \psi, \neg\psi(\bar{a}, \bar{z}) \text{ is satisfiable, and } h \vdash_{\leq m} \varphi(\bar{x}, \bar{y}) \rightarrow \psi(\bar{x}, \bar{z}) \}\.
\]

Let us first argue that \( \text{Int}(h) \) is indeed a disjoint \( \text{NP} \)-pair. Clearly, both components are in \( \text{NP} \). To verify the disjointness, assume that \( \langle \varphi(\bar{x}, \bar{y}), \psi(\bar{x}, \bar{z}), \bar{a}, 0^m \rangle \) is contained in \( \text{Int}_1(h) \). Since we have an \( h \)-proof, the formula \( \varphi(\bar{x}, \bar{y}) \rightarrow \psi(\bar{x}, \bar{z}) \) is a tautology. By assumption, \( \varphi(\bar{a}, \bar{y}) \) is satisfiable and hence \( \psi(\bar{a}, \bar{z}) \) must be a tautology. Therefore, \( \neg\psi(\bar{a}, \bar{z}) \) is unsatisfiable which implies \( \langle \varphi(\bar{x}, \bar{y}), \psi(\bar{x}, \bar{z}), \bar{a}, 0^m \rangle \notin \text{Int}_2(h) \).

Before we start to explain the link of the interpolation pair to different notions of interpolation, let us mention a general connection between propositional proof systems and disjoint \( \text{NP} \)-pairs. For this connection, disjoint \( \text{NP} \)-pairs are represented by sequences of propositional formulas (cf. [3]). The formal definition is as follows: A propositional representation for an \( \text{NP} \)-set \( A \) is a sequence of propositional formulas \( \varphi_n(\bar{x}, \bar{y}) \) with the following properties:

1. \( \varphi_n(\bar{x}, \bar{y}) \) has propositional variables \( \bar{x} \) and \( \bar{y} \) such that \( \bar{x} \) is a vector of \( n \) propositional variables.
2. There exists a polynomial-time algorithm that on input \( 1^n \) outputs \( \varphi_n(\bar{x}, \bar{y}) \).
3. Let \( \bar{a} \in \{0,1\}^n \). Then \( \bar{a} \in A \) if and only if \( \varphi_n(\bar{a}, \bar{y}) \) is satisfiable (where we have substituted the propositional variables \( \bar{x} \) by the bits \( \bar{a} \)).
With these propositional descriptions of NP-sets we can represent disjoint NP-pairs in propositional proof systems. We say that a disjoint NP-pair \((A, B)\) is representable in a propositional proof system \(h\) if there are propositional representations \(\varphi_n(x, y)\) of \(A\) and \(\psi_n(x, z)\) of \(B\) such that \(x\) are the common variables of \(\varphi_n(x, y)\) and \(\psi_n(x, z)\) and \(h \vdash_{\leq p(n)} \varphi_n(x, y) \rightarrow \neg \psi_n(x, z)\) for some polynomial \(p\).

Let us remark at this point that every disjoint NP-pair \((A, B)\) is representable in some propositional proof system by simply coding a representation of \((A, B)\) into a given base system. As a concrete example, let us explain how this works for the extended Frege proof system \(EF\) (cf. [11]). If \(\varphi_n(x, y)\) and \(\psi_n(x, z)\) are propositional representations for the NP-sets \(A\) and \(B\), respectively, then the pair \((A, B)\) is representable in the system \(EF + \{\varphi_n(x, y) \rightarrow \neg \psi_n(x, z) \mid n \geq 0\}\) which augments \(EF\) by additional axioms for the disjointness of the pair \((A, B)\). Such extensions \(EF + \Phi\) by polynomial-time decidable sets \(\Phi\) of tautologies are of particular interest, as every propositional proof system is simulated by such a system \(EF + \Phi\) for suitable axioms \(\Phi\) (cf. [30]).

Before we explain how the interpolation pair \(Int(h)\) captures effective interpolation for \(h\), we will show that \(Int(h)\) serves as a hard pair for the class of all pairs representable in the system \(h\) (this class was investigated in detail in [3] under the name \(DNPP(h)\)). We formulate this observation in the next proposition.

**Proposition 11.** For every proof system \(h\) the interpolation pair \(Int(h)\) is \(\leq_s\)-hard for the class of all disjoint NP-pairs that are representable in \(h\).

**Proof.** Let \(h\) be a proof system and let \((A, B)\) be a disjoint NP-pair such that \(\varphi_n(x, y)\) and \(\psi_n(x, z)\) represent \(A\) and \(B\), respectively, and \(h \vdash_{\leq p(n)} \varphi_n(x, y) \rightarrow \neg \psi_n(x, z)\) for some polynomial \(p\). It is then straightforward to verify that

\[
a \mapsto \langle \varphi_{|a|}(x, y), \neg \psi_{|a|}(x, z), a, 0^{p(|a|)} \rangle
\]

realizes the reduction \((A, B) \leq_s Int(h)\). \(\square\)

Now we want to argue that \(Int(h)\) indeed justifies its qualification as a pair that describes the effective interpolation property. To this end we consider for a given proof system \(h\) the following three assertions:

\begin{itemize}
  \item \(A_1(h)\): The interpolation pair \(Int(h)\) is \(P/poly\)-separable.
  \item \(A_2(h)\): \(h\) has effective interpolation.
  \item \(A_3(h)\): All NP-pairs that are representable in \(h\) are \(P/poly\)-separable.
\end{itemize}

Then the following implications between these assertions hold.

**Proposition 12.**

1. For all propositional proof systems \(h\) the implications \(A_1(h) \Rightarrow A_2(h) \Rightarrow A_3(h)\) hold.
2. Let \(h\) be a proof system of the form \(EF + \Phi\) with a polynomial-time decidable set of tautologies \(\Phi\). Then the equivalences \(A_1(h) \Leftrightarrow A_2(h) \Leftrightarrow A_3(h)\) hold.
Proof. To prove the implication $A_1(h) \Rightarrow A_2(h)$ for arbitrary proof systems $h$, assume that $\text{Int}(h)$ is separated by the polynomial-size circuit family $C_n$, i.e., for inputs $(\varphi(\bar{x}, \bar{y}), \psi(\bar{x}, \bar{z}), a, 0^n)$ of length $n$ from $\text{Int}_1(h)$ the circuit $C_n$ outputs 1, and $C_n$ outputs 0 for inputs from $\text{Int}_2(h)$.

Let $\varphi(\bar{x}, \bar{y}) \rightarrow \psi(\bar{x}, \bar{z})$ be an implication that has an $h$-proof of length $m$. By substituting $\varphi$, $\psi$, and $0^m$ for the respective input gates of the appropriate circuit $C_n$, we obtain a circuit with inputs $\bar{x}$ that interpolates $\varphi$ and $\psi$.

For the implication $A_2(h) \Rightarrow A_3(h)$ let $(A, B)$ be a disjoint NP-pair that is representable in $h$ with respect to the representations $\varphi_n(\bar{x}, \bar{y})$ and $\psi_n(\bar{x}, \bar{z})$, i.e., we have $h$-proofs of length $\leq p(n)$ for the sequence of formulas $\varphi_n(\bar{x}, \bar{y}) \rightarrow \neg \psi_n(\bar{x}, \bar{z})$ with some polynomial $p$. As $h$ has effective interpolation by $A_2(h)$, there exist interpolating circuits $C_n(\bar{x})$ for $\varphi_n(\bar{x}, \bar{y}) \rightarrow \neg \psi_n(\bar{x}, \bar{z})$. Hence the circuit family $C_n$ provides a separator for $(A, B)$.

For item 2 it remains to show the implication $A_3(h) \Rightarrow A_1(h)$ for proof systems $h$ of the form $EF + \Phi$ with polynomial-time decidable set $\Phi \subseteq \text{TAUT}$. For this it suffices to prove the representability of $\text{Int}(h)$ in the system $h$, i.e., we have to construct representations of $\text{Int}(h)$ such that $h$ admits short proofs for the disjointness of $\text{Int}_1(h)$ and $\text{Int}_2(h)$ with respect to these representations. Such representations arise from translations of natural arithmetic formulas defining the components of $\text{Int}(h)$. Using reflection for extensions of $EF$, it is then straightforward to verify the disjointness of $\text{Int}(h)$ in the system $h$ (cf. [3, 5] for a detailed description of this procedure).

To capture the feasible interpolation property, Pudlák [42] defines an interpolation pair $(I^0_h, I^1_h)$ for a proof system $h$ with the components

$$I^i_h = \{ (\varphi_0, \varphi_1, \pi) \mid \varphi_0 \text{ and } \varphi_1 \text{ do not share variables, } \neg \varphi_i \text{ is satisfiable, }$$
$$\text{and } h(\pi) = \varphi_0 \lor \varphi_1 \}$$

for $i = 0, 1$. Let us briefly argue for the disjointness of the pair: The proof $\pi$ ensures that $\varphi_0 \lor \varphi_1$ is tautological and since $\varphi_0$ and $\varphi_1$ do not share variables, one of the formulas $\varphi_0$ or $\varphi_1$ must itself be a tautology. Therefore, $\neg \varphi_0$ and $\neg \varphi_1$ cannot be both satisfiable and hence $I^0_h \cap I^1_h = \emptyset$. Under reasonable assumptions on the proof system $h$, we can then show a similar result as in Proposition 12 for $(I^0_h, I^1_h)$ and the efficient analogues of $A_1(h)$ to $A_3(h)$. In particular, $h$ has feasible interpolation if and only if $(I^0_h, I^1_h)$ is $P$-separable (assuming some simple closure properties of $h$ such as closure under substitution by constants, cf. [42]). The pair $(I^0_h, I^1_h)$ is, however, not suitable for the notion of effective interpolation, for which reason we have defined its nonuniform version $\text{Int}(h)$.

As mentioned above, weak systems like resolution or cutting planes are known to possess effective interpolation [7, 31, 40]. In contrast, there is evidence that strong propositional proof systems like Frege systems and their extensions do not admit effective interpolation [33, 8, 6]. In particular, it is observed in [33] that extended Frege proof systems do not admit effective interpolation if the RSA cryptosystem is secure.

Partly generalizing this observation, one can state that the existence of an honest injective function in FP that is not FP/poly-invertible (i.e., a one-way
function that is secure against $\text{FP/poly}$) implies the existence of a proof system for $\text{TAUT}$ that does not admit effective interpolation. Notice that each injective function in $\text{FP}$ is invertible by an $\text{NPSV}$-function. Thus the assumption that each $\text{NPSV}$-function has a total extension in $\text{FP/poly}$ implies that every injective function is $\text{FP/poly}$-invertible. As the former assumption implies $\text{NP} \cap \text{coNP} \subseteq \text{P/poly}$ and the latter is equivalent to $\text{UP} \subseteq \text{P/poly}$ (cf. [26, 22]), the former assumption is presumably stronger. We now show that every function in $\text{NPSV}$ has a total extension in $\text{FP/poly}$ if and only if every proof system for $\text{TAUT}$ admits effective interpolation.

**Theorem 13.** *The following statements are equivalent.*

1. Every propositional proof system admits effective interpolation.
2. Every disjoint $\text{NP}$-pair is $\text{P/poly}$-separable.
3. Every function in $\text{NPSV}$ has a total extension in $\text{FP/poly}$.
4. For every set $S \subseteq \text{TAUT}$, $S \in \text{NP}$, there is a polynomial $p$, such that any formula $\varphi \rightarrow \psi \in S$ has an interpolant of size at most $p(|\varphi \rightarrow \psi|)$.
5. For every printable set $S \subseteq \text{TAUT}$, there is a polynomial $p$, such that any formula $\varphi \rightarrow \psi \in S$ has an interpolant of size at most $p(|\varphi \rightarrow \psi|)$.

**Proof.** For the proof we will show the implications $1 \Rightarrow 2 \Rightarrow 3 \Rightarrow 4 \Rightarrow 5$ as well as $4 \Rightarrow 1$ and $5 \Rightarrow 2$. The implication $4 \Rightarrow 5$ is immediate, as item 5 is a weakening of item 4.

Items 1 and 2 are the universally quantified versions of the assertions $A_2(h)$ and $A_3(h)$, respectively, i.e., item 1 expresses that $A_2(h)$ holds for all propositional proof systems $h$. Similarly, this holds for item 2 and assertion $A_3(h)$, as every disjoint $\text{NP}$-pair $(A, B)$ is representable in a proof system $\text{EF} + \{\varphi_n \rightarrow \neg \psi_n\}$ with arbitrary representations $\varphi_n$ and $\psi_n$ for $A$ and $B$, respectively. Therefore the equivalence of items 1 and 2 is a direct consequence of Proposition 12.

The implication $2 \Rightarrow 3$ was shown in [52], but for the sake of completeness we include a proof. Assume that all disjoint $\text{NP}$-pairs are $\text{P/poly}$-separable, and let $f$ be a function in $\text{NPSV}$. With $f$ we associate a pair $(A_0^f, A_1^f)$ with the components

$$A_i^f = \{(x, j) \mid (\exists y) y \in \text{set-}f(x), 1 \leq j \leq |y|, \text{ and the } j\text{-th bit of } y \text{ is } i\}.$$  

This disjoint $\text{NP}$-pair describes all bits of the values of $f$. To determine the length of $f$-values we define a second $\text{NP}$-pair $(B_0^f, B_1^f)$ with the components

$$B_0^f = \{(x, j) \mid (\exists y) y \in \text{set-}f(x) \text{ and } j \leq |y|\}$$

$$B_1^f = \{(x, j) \mid (\exists y) y \in \text{set-}f(x) \text{ and } j > |y|\}.$$  

By assumption the pairs $(A_0^f, A_1^f)$ and $(B_0^f, B_1^f)$ can be separated by polynomial-size circuit families $C_n$ and $D_n$, respectively. Using these circuits we devise a function $g \in \text{FP/poly}$ that refines $f$ as follows. Let $p$ be a polynomial bounding the running time of $f$. At input $x$, the function $g$ evaluates all respective circuits from $D_n$ on inputs $\langle x, 1 \rangle, \ldots, \langle x, p(|x|) + 1 \rangle$ to determine the length $l$ of the possible output value of $f(x)$. After $l$ is computed, $g$ evaluates the circuits $C_n$.
on inputs $(x, 1), \ldots, (x, l)$. The output of $g$ is then just the bitwise concatenation of these values. From the construction it is clear that $g \in \text{FP/poly}$ refines the function $f$.

The proof of the implication $3 \Rightarrow 4$ is obtained by extending an idea from [52]. Let $S \subseteq \text{TAUT}, S \in \text{NP}$. Let $f$ be a function such that for any formula $\varphi \in S$, $\varphi = \varphi_0(\bar{x}, \bar{y}) \rightarrow \varphi_1(\bar{x}, \bar{z})$, it holds

$$f((\alpha, \varphi)) = \begin{cases} 1 & \text{if for some } \beta, \varphi_0(\alpha, \beta) \text{ holds} \\ 0 & \text{if for some } \gamma, \neg \varphi_1(\alpha, \gamma) \text{ holds.} \end{cases}$$

Otherwise, and for any other input let $f$ be undefined. First observe that $f$ is well defined, i.e., that $f$ is single valued. This is due to the fact that $\varphi = \varphi_0(\bar{x}, \bar{y}) \rightarrow \varphi_1(\bar{x}, \bar{z}) \in \text{TAUT}$. Further, $f$ can be computed by a nondeterministic machine $N$ that first (in deterministic polynomial time) validates that the input is of the appropriate form $(\alpha, \varphi), \varphi = \varphi_0(\bar{x}, \bar{y}) \rightarrow \varphi_1(\bar{x}, \bar{z})$. Then $N$ guesses a certificate for $\varphi \in S$ and, if successful, guesses some string $w$. Now if $w$ is of an appropriate length and if $\varphi_0(\alpha, w)$ holds, then $N$ outputs 1, if $\varphi_1(\alpha, w)$ holds, $N$ outputs 0. Hence $f \in \text{NPSV}$.

Assuming 3, $f$ has a total extension in $\text{FP/poly}$. Thus there is a polynomial $p$ and for any $n \geq 0$ a circuit $C_n$ of size at most $p(n)$ such that for any tuple $v = (\alpha, \varphi)$ of length $n$ in the domain of $f$, $C_n(v) = f(v)$. Fixing the input bits of $C_n$ that belong to the formula $\varphi$, we obtain a circuit $C_\varphi$ with $C_\varphi(\alpha) = C_n((\alpha, \varphi)) = f((\alpha, \varphi))$, and thus $C_\varphi$ is of size polynomial in $|\varphi|$. Now observe that $C_\varphi$ is an interpolant for the formulas $\varphi_0(\bar{x}, \bar{y})$ and $\varphi_1(\bar{x}, \bar{z})$. If $\varphi_0(\alpha, \bar{y}) \in \text{SAT}$, then $C_\varphi(\alpha) = 1$, and if $C_\varphi(\alpha) = 1$, then for no $\gamma$ it holds $\neg \varphi_1(\alpha, \gamma)$ and therefore $\varphi_1(\alpha, \bar{z}) \in \text{TAUT}$.

To prove the implication $4 \Rightarrow 1$, let pad: $\Sigma^* \times \{0\}^* \rightarrow \Sigma^*$ be a function in $\text{FP}$ with the following properties:

1. pad$(\chi, 0^n) \in \text{TAUT}$ if and only if $\chi \in \text{TAUT}$.
2. given an implication $\varphi \rightarrow \psi \in \text{TAUT}$ as an input, the output pad$(\varphi \rightarrow \psi, 0^n)$ is also an implication $\varphi' \rightarrow \psi'$ that has the same interpolants as $\varphi \rightarrow \psi$.
3. $|\text{pad}(\chi, 0^n)| \geq |\chi| + n$.

Notice that there is such a padding function. Now let $h$ be a proof system for $\text{TAUT}$, and let

$$S = \{ \chi \mid \exists n \leq |\chi| \exists w, |w| \leq n, \text{ pad}(h(w), 0^n) = \chi \}.$$  

Clearly $S \in \text{NP}$, as pad and $h$ are functions in $\text{FP}$. Because $h$ is a proof system for $\text{TAUT}$ and due to property 1 of pad, $S \subseteq \text{TAUT}$. Thus by assumption 4 there is a monotone polynomial $p$, such that any formula $\varphi' \rightarrow \psi' \in S$ has an interpolant of size at most $p(|\varphi' \rightarrow \psi'|)$. As pad, $h \in \text{FP}$ there are monotone polynomials $q, r$ such that $|h(w)| \leq q(|w|)$ and $|\text{pad}(\chi, 0^n)| \leq r(|\chi| + n)$ for any $w, \chi \in \Sigma^*, n \geq 0$.

Let $\varphi \rightarrow \psi \in \text{TAUT}$ and let $w$ be an $h$-proof for $\varphi \rightarrow \psi$. Now by property 3 of pad $\varphi' \rightarrow \psi' = \text{pad}(\varphi \rightarrow \psi, 0^{|w|}) \in S$, therefore by the property 2 of pad, $\varphi \rightarrow \psi$ has an interpolant of size at most $p(|\varphi' \rightarrow \psi'|) \leq p(r(|w|) + |w|))$. 

16
To finish the proof let us show that the implication $5 \implies 2$ holds. Let $(A, B)$ be a disjoint NP-pair. We choose arbitrary representations $\varphi_n(\bar{x}, \bar{y})$ for $A$ and $\psi_n(\bar{x}, \bar{z})$ for $B$. By the disjointness of $A$ and $B$, $\varphi_n(\bar{x}, \bar{y}) \implies \neg \psi_n(\bar{x}, \bar{z})$ is a printable sequence of tautologies. Assuming $5$ we get polynomial-size interpolating circuits for these formulas. These circuits separate the pair $(A, B)$. □

Part of the equivalences of the last theorem were already shown by Schöning and Torán [52]. There they proved that items 2, 3, and 5 are equivalent, and that these hypotheses imply $\text{NP} \cap \text{coNP} \subseteq \text{P/poly}$ and $\text{UP} \subseteq \text{P/poly}$. Let us note that Theorem 13 also holds in an efficient version, where $\text{FP/poly}$ is replaced by $\text{FP}$, and effective interpolation is strengthened to feasible interpolation. It is readily checked that the proof of Theorem 13 is easily modified to this efficient context. Hence Theorem 13 along with its proof yield the following corollary:

**Corollary 14.** The following statements are equivalent.

1. Every propositional proof system admits feasible interpolation.
2. Every disjoint NP-pair is P-separable.
3. Every function in NPSV has a total extension in FP.

Let us mention that the above list of equivalences also relates to the important concept of automatizability, as recently noted by Sadowski [49]. In [8] a proof system $h$ is called *automatizable* if there exists a deterministic procedure that takes as input a formula $\varphi$ and outputs an $h$-proof of $\varphi$ in time polynomial in the length of the shortest $h$-proof of $\varphi$. A proof system $g$ is called *weakly automatizable* if there exists an automatizable system $h$ that simulates $g$ (cf. [42]). In [49] Sadowski proves that items 2 and 3 from Corollary 14 are equivalent to the statement that every propositional proof system is weakly automatizable.

It is easy to see that a proof system $g$ admits effective interpolation if $g$ is simulated by a proof system $h$ that admits effective interpolation. As a corollary from Theorem 13 we obtain:

**Corollary 15.** If there is an optimal proof system for TAUT that admits effective interpolation, then items 1 to 5 from Theorem 13 hold.

## 5 Is the Standard Proof System for SAT P-optimal?

In this section we will consider the question whether the standard proof system for SAT is p-optimal, where by the standard proof system $\text{Sat}$ for SAT we mean the following procedure of checking the truth value of a given assignment:

$$\text{Sat}(x) = \begin{cases} \varphi & \text{if } x = (\alpha, \varphi) \text{ and } \alpha \text{ is a satisfying assignment for } \varphi \\ \text{undef.} & \text{otherwise.} \end{cases}$$

As $\text{Sat}$ is polynomially bounded (i.e. every satisfiable formula has a polynomial-size proof in $\text{Sat}$), the system $\text{Sat}$ is an optimal proof system for SAT. It will turn out that the question whether $\text{Sat}$ is even p-optimal is (in some disguise) actually well studied in the literature. The assumption that $\text{Sat}$ is p-optimal is
equivalent to a variety of complexity-theoretic assumptions (which have unlikely collapse consequences such as $P = NP \cap \text{coNP}$).

In [14] the following statements were all shown to be equivalent. There, $Q$ is defined to be the proposition that one (and consequently each) of these statements is true. In this section we show that $Q$ is also equivalent to the $p$-optimality of $\text{sat}$.

**Theorem 16 (Fenner, Fortnow, Naik, Rogers [14]).** The following statements are equivalent.

1. For each NPTM $N$ that accepts $\text{SAT}$ there is a function $f \in \text{FP}$ such that for each accepting path $\alpha$ of $N$ on input $\varphi$, $f(\langle \varphi, \alpha \rangle)$ is a satisfying assignment of $\varphi$.
2. Each honest function $f \in \text{FP}$ with range $\Sigma^*$ is $\text{FP}$-invertible.
3. $\text{NPMV}_f \subseteq \text{FP}$.
4. For each $\text{P}$-subset $S$ of $\text{SAT}$ there exists a function $g \in \text{FP}$ such that for all $\varphi \in S$, $g(\varphi)$ is a satisfying assignment of $\varphi$.

Clearly, each nondeterministic Turing machine $N$ corresponds to a proof system $h$ for $\text{SAT}$ with $h(w) = \varphi$ if $w$ encodes an accepting path of $N$ on input $\varphi$. Now $h$ is honest if and only if $N$ is a NPTM. This leads to the observation that Statement 1 in Theorem 16 is equivalent to the condition that $\text{sat}$ $p$-simulates every proof system $h$ for $\text{SAT}$ where $h$ happens to be an honest function. Hence, we just need to delete the term ‘polynomial-time’ in the Statement 1 of Theorem 16 to obtain the desired result that $Q$ is equivalent to the $p$-optimality of $\text{sat}$. That this is possible without changing the truth of the theorem is shown by a padding argument.

**Theorem 17.** The following statements are equivalent.

1. For each nondeterministic Turing machine $N$ that accepts $\text{SAT}$ there is a function $f \in \text{FP}$ such that for each accepting path $\alpha$ of $N$ on input $\varphi$, $f(\langle \varphi, \alpha \rangle)$ is a satisfying assignment of $\varphi$.
2. For each NPTM $N$ that accepts $\text{SAT}$ there is a function $f \in \text{FP}$ such that for each accepting path $\alpha$ of $N$ on input $\varphi$, $f(\langle \varphi, \alpha \rangle)$ is a satisfying assignment of $\varphi$.
3. $\text{sat}$ is a $p$-optimal proof system for $\text{SAT}$.

**Proof.** By the preceding discussion, it is clear that items 1 and 3 are equivalent. Also, item 1 trivially implies item 2. Hence it remains to prove that 2 implies 3.

For this assume that item 2 holds, and let $h$ be a proof system for $\text{SAT}$. We will show that $\text{sat}$ $p$-simulates $h$. Let $\top$ be some tautology, and let $\top^1 = \top$, $\top^n = \top \land \top^{n-1}$ for $n \geq 2$ (i.e., $\top^n$ is a tautology of length $\geq n$ that is easy to compute from $0^n$). Let $h' \in \text{FP}$ be a proof system defined by

$$h'(x) = \begin{cases} \varphi \land \top^{|x| - 1} & \text{if } x = 1w \text{ and } h(w) = \varphi, \\ \varphi & \text{if } x = 0w \text{ and } \text{sat}(w) = \varphi, \\ \text{undef.} & \text{otherwise.} \end{cases}$$
Notice that \( h' \) is honest. Hence, \( \text{sat} \) \( p \)-simulates \( h' \) by the following argument. Let \( N_{h'} \) be a nondeterministic polynomial-time Turing machine that on input \( y \) guesses some \( w \) and accepts if \( h'(w) = y \). Since \( N_{h'} \) accepts \( \text{SAT} \), by item 2 there is a function \( f \in \text{FP} \) such \( f((y, \alpha)) \) is a satisfying assignment of \( y \) for any accepting path \( \alpha \) of \( N_{h'} \) on input \( y \). Thus there is a function \( f' \in \text{FP} \) with \( \text{sat}(f'(w)) = \varphi \land \top^{|w|} \) for any \( w \) with \( h(w) = \varphi \). But it is clear that from a satisfying assignment of \( \varphi \land \top^{|w|} \) we can easily compute a satisfying assignment of \( \varphi \), i.e., there is a function \( g \) with \( \text{sat}(g(f'(w), h(w))) = h(w) \) for any \( w \) in the domain of \( h \).

It is known that the assumption \( \text{NP} = \text{P} \) implies \( \text{NPMV}_t \subseteq \text{FP} \) which in turn implies \( \text{NP} \cap \text{coNP} = \text{P} \) (cf. [55]). Also, in [25] it has been shown that the converse of these implications is not true in suitable relativized worlds. The consequence \( \text{NP} \cap \text{coNP} = \text{P} \) also shows that the assumption that \( \text{sat} \) is \( p \)-optimal is presumably stronger than the assumption that \( \text{SAT} \) has a \( p \)-optimal proof system. Namely the \( p \)-optimality of \( \text{sat} \) implies that \( \text{NP} \cap \text{coNP} = \text{P} \), whereas the existence of a \( p \)-optimal proof system follows already if any super-tally set in \( \Sigma^p_0 \) belongs to \( \text{P} \), where any set \( L \subseteq \{0^{2^n} \mid n \geq 0 \} \) is called super-tally [28].

The assumption that \( \text{sat} \) is a \( p \)-optimal proof system also has an effect on various reducibility degrees, as has been mentioned in [14] for Karp and Levin reducibility. Also in [35] it is shown that \( \text{NPMV}_t \subseteq \text{FP} \) if and only if \( \gamma \)-reducibility equals polynomial-time many-one reducibility. Furthermore it is shown in [13] that Statement 4 of Theorem 16 is equivalent to the assumption that the approximation class \( \text{APX} \) is closed under \( L \)-reducibility (see [13] for definitions).

The equivalence between the \( p \)-optimality of \( \text{sat} \) and \( \text{NPMV}_t \subseteq \text{FP} \) directly leads to the following theorem.

**Theorem 18.** The following statements are equivalent.

1. \( \text{sat} \) is \( p \)-optimal.
2. For all languages the notions of simulation and \( p \)-simulation coincide, i.e., for every language \( L \) and all proof systems \( h \) and \( g \) for \( L \) we have \( g \leq_p h \) if and only if \( g \leq_h h \).
3. The notions of simulation and \( p \)-simulation coincide for propositional proof systems, i.e., for all propositional proof systems \( h \) and \( g \) we have \( g \leq_p h \) if and only if \( g \leq_h h \).
4. Every optimal proof system is \( p \)-optimal.

**Proof.** We will show the implications \( 1 \Rightarrow 2 \Rightarrow 3 \Rightarrow 1 \) and \( 2 \Rightarrow 4 \Rightarrow 1 \), of which \( 2 \Rightarrow 3 \) and \( 2 \Rightarrow 4 \) are obvious, and \( 4 \Rightarrow 1 \) follows, because \( \text{sat} \) is optimal.

To show the implication \( 1 \Rightarrow 2 \), assume that \( \text{sat} \) is a \( p \)-optimal proof system. Clearly, if \( h \) \( p \)-simulates \( g \), then \( h \) also simulates \( g \).

Therefore, let us assume that \( h \) simulates \( g \). Then there is a polynomial \( p \) such that for every \( x \) in the domain of \( g \) there is some \( w \) of length at most \( p(|x|) \) with \( g(x) = h(w) \). Let \( N \) be a nondeterministic polynomial-time Turing machine that on input of any \( x \) in the domain of \( g \) guesses some \( w \) of length \( \leq p(|x|) \) and outputs \( w \) if \( h(w) = g(x) \) (if \( x \) is not in the domain of \( g \), which can be decided in
polynomial time, \( N \) outputs \( \lambda \)). Clearly, \( N \) computes a function in \( \text{NPMV}_t \). As by assumption \( \text{sat} \) is p-optimal, we get \( \text{NPMV}_t \subseteq \text{FP} \) by Theorems 16 and 17. Hence there exists a function \( f \in \text{FP} \) with \( h(f(x)) = g(x) \) for every \( x \) in the domain of \( g \). Therefore \( h \) p-simulates \( g \).

Now we prove the remaining implication \( 3 \Rightarrow 1 \). For this let \( g \) be an arbitrary propositional proof system, and let \( N \) be an NPTM for SAT. From \( g \) and \( N \) we define a propositional proof system \( h_1 \) by

\[
h_1(\pi) = \begin{cases} 
  g(\pi') & \text{if } \pi = 0\pi', \text{ and } g(\pi') \text{ is not of the form } \top \lor \varphi \\
  \top \lor \varphi & \text{with some propositional formula } \varphi \\
  \top \lor \varphi & \text{if } \pi = 1\langle \varphi, 1^m \rangle \text{ and } m \geq 2^{||\varphi||} \\
  \top \lor \varphi & \text{if } \pi = 1\langle \varphi, w \rangle \text{ and } w \text{ is an accepting path of } N(\varphi) \\
  \top & \text{otherwise}, 
\end{cases}
\]

where \( \top \) stands for a fixed tautology. Clearly, \( h_1 \) is computable in polynomial time and outputs only tautologies. Moreover, all tautologies appear in the range of \( h_1 \), according to the first two lines of its definition. Hence \( h_1 \) is a propositional proof system.

Similarly, we construct a propositional proof system \( h_2 \) by replacing \( N \) by \( \text{sat} \) in the third line of the definition of \( h_1 \).

\[
h_2(\pi) = \begin{cases} 
  g(\pi') & \text{if } \pi = 0\pi', \text{ and } g(\pi') \text{ is not of the form } \top \lor \varphi \\
  \top \lor \varphi & \text{with some propositional formula } \varphi \\
  \top \lor \varphi & \text{if } \pi = 1\langle \varphi, 1^m \rangle \text{ and } m \geq 2^{||\varphi||} \\
  \top \lor \varphi & \text{if } \pi = 1\langle \varphi, \alpha \rangle \text{ and } \alpha \text{ is a satisfying assignment for } \varphi \\
  \top & \text{otherwise}. 
\end{cases}
\]

Obviously, \( h_1 \) and \( h_2 \) are equivalent, as they differ only in proofs for formulas \( \top \lor \varphi \) with \( \varphi \in \text{SAT} \), and these tautologies have polynomial-size proofs in both \( h_1 \) and \( h_2 \) (these formulas also have exponential-size proofs in both systems). Thus, assuming \( 3 \), \( h_1 \) and \( h_2 \) are p-equivalent. Let \( f \in \text{FP} \) compute a p-simulation of \( h_1 \) by \( h_2 \), and let \( w \) be an accepting path of \( N \) on input \( \varphi \). Then \( f \) computes on input \( 1\langle \varphi, w \rangle \) a satisfying assignment \( \alpha \) for \( \varphi \) (the complete output of \( f \) is \( 1\langle \varphi, \alpha \rangle \)). Thus assertion 2 of Theorem 17 holds, which we have already shown to be equivalent to the p-optimality of \( \text{sat} \) in Theorem 17. \( \square \)

The equivalence \( 2 \Leftrightarrow 3 \) of the preceding theorem states that any simulation of a propositional proof system can be turned into a p-simulation if and only if any simulation of an arbitrary proof system can be turned into a p-simulation. In contrast, we cannot expect a similar equivalence with respect to the existence of optimal and p-optimal proof systems since item 4 of the previous theorem is probably stronger than the statement that every optimal propositional proof system is p-optimal. The reason for this is that optimal propositional proof systems are unlikely to exist (cf. [28]). Therefore, item 4 restricted to propositional proof systems would be trivially true, whereas item 4 is probably false, as it is equivalent to \( Q \) and hence leads to unlikely collapse consequences.
In [36] it has been observed that given a p-optimal proof system $h$ for a language $L$, the problem to find an $h$-proof for $y \in L$ is not much harder than deciding $L$. More precisely, we can transform each deterministic Turing machine $M$ with $L(M) = L$ to a deterministic Turing machine $M'$ that on input $y \in L$ yields an $h$-proof of $y$ in time $\text{time}_{M'}(y) \leq p(|y| + \text{time}_M(y))$, for some polynomial $p$ determined by $M$. Using this observation and the equivalences in Theorems 16 and 17 we obtain the following result: sat is p-optimal if and only if any deterministic Turing machine $M$ that accepts SAT can be converted to a deterministic Turing machine that computes a satisfying assignment for any formula $\varphi \in \text{SAT}$ and runs not much longer than $M$ on input $\varphi$.

**Theorem 19.** The following statements are equivalent.

1. sat is p-optimal.
2. For any deterministic Turing machine $M$ that accepts SAT in $\text{time}_M(\varphi)$ steps for any $\varphi \in \text{SAT}$, there is a deterministic Turing machine $M'$ and a polynomial $p$ such that for every $\varphi \in \text{SAT}$, $M'$ produces a satisfying assignment of $\varphi$ in time $\text{time}_{M'}(\varphi) \leq p(|\varphi| + \text{time}_M(\varphi))$ steps.

**Proof.** It is easy to see that 2 implies Statement 4 of Theorem 16: Combine a polynomial-time machine that decides a P-subset $S$ of SAT with a standard machine that decides SAT to obtain a machine $M$ for SAT whose running time $\text{time}_M(\varphi)$ is polynomial in $|\varphi|$ for $\varphi \in S$. Assuming 2 there is a machine $M'$ that on input $\varphi \in S$ produces a satisfying assignment of $\varphi$ in time polynomial in $|\varphi|$.

To show the implication 1 $\Rightarrow$ 2 assume that sat is p-optimal. Let $M$ be an arbitrary deterministic Turing machine that decides SAT. We will construct a suitable machine $M'$ to show that 2 holds. Define a proof system $h_M$ for SAT with $h_M(\langle \varphi, 0^s \rangle) = \varphi$ if $M$ accepts $\varphi$ in at most $s$ steps. As sat is p-optimal there is a function $g \in \text{FP}$ with $\text{sat}(g(x)) = h_M(x)$ for each $x$ in the domain of $h_M$. Now on input $\varphi$, $M'$ simulates $M$. If $M$ accepts after $s$ steps, $M'$ computes the sat-proof $g(\langle \varphi, 0^s \rangle)$ of $\varphi$ and extracts the satisfying assignment. Otherwise $M'$ rejects. Clearly, on input $\varphi \in \text{SAT}$, $M'$ needs time at most polynomial in $|\varphi| + \text{time}_M(\varphi)$. \qed

Under the assumption that sat is not p-optimal it follows from Theorem 19 that there is a Turing machine $M$ that decides SAT such that any machine $M'$ that on input $\varphi \in \text{SAT}$ has to produce a satisfying assignment for $\varphi$ is much slower on some SAT instances. In some sense this appears counter-intuitive as probably all SAT algorithms used in practice produce a satisfying assignment in case the input belongs to SAT. Of course it follows from Theorem 19 that $M$ is superior to any such $M'$ on an infinite set of instances. As shown in the following theorem $M$ is even superior to any $M'$ on a fixed non-sparse set of SAT instances. The result is due to the paddability of SAT, and uses ideas from the theory of complexity cores (cf. [51]).

**Theorem 20.** The following statements are equivalent.

1. sat is not p-optimal.
2. There is a $P$-subset $S$ of SAT such that for any deterministic Turing machine $M'$ that on input $\varphi \in S$ produces a satisfying assignment of $\varphi$ and for any polynomial $p$ the set

$$\{ \varphi \in S \mid \text{time}_{M'}(\varphi) > p(|\varphi|) \}$$

is not sparse.

3. There is a $P$-subset $S$ of SAT, a non-sparse subset $L$ of $S$, and a super-polynomial function $f$ such that for any deterministic Turing machine $M'$ that on input $\varphi \in S$ produces a satisfying assignment of $\varphi$

$$\text{time}_{M'}(\varphi) > f(|\varphi|)$$

for almost every $\varphi \in L$.

4. There is a machine $M$ accepting SAT, a non-sparse subset $S$ of SAT, and a super-polynomial function $f$ such that for any deterministic Turing machine $M'$ that on input $\varphi \in SAT$ produces a satisfying assignment of $\varphi$

$$\text{time}_{M'}(\varphi) > f(|\varphi| + \text{time}_M(\varphi))$$

for almost every $\varphi \in S$.

Proof. Let $\text{pad}: \Sigma^* \times \Sigma^* \rightarrow \Sigma^*$ be an injective function that is $FP$-invertible with the following further properties

1. $\text{pad}(\varphi, w) \in \text{SAT}$ if and only if $\varphi \in \text{SAT}$.
2. From a $\text{sat}$-proof for $\psi = \text{pad}(\varphi, w)$ one can easily compute a satisfying assignment for $\varphi$.
3. $|\text{pad}(\varphi, w)| = |\varphi| + c(|w| + 1)$ for some constant $c$.

Notice that there is such a padding function.

To see that item 1 implies item 2, assume that the contrary of 2 holds. We will see that this implies Statement 4 in Theorem 16 which completes the proof of this implication. Let $S$ be an arbitrary $P$-subset of SAT and let

$$T = \{ \text{pad}(\varphi, w) \mid w \in \Sigma^*, \varphi \in S \}.$$ 

As pad is invertible we also have $T \in P$. Assuming the contrary of 2 there is a polynomial $p$ and a deterministic Turing machine $M'$ that on input $\varphi \in T$ produces a satisfying assignment of $\varphi$ such that the set

$$Q = \{ \varphi \in T \mid \text{time}_{M'}(\varphi) > p(|\varphi|) \}$$

is sparse. Let $q$ be a polynomial bound for the density of $Q$ (i.e., $|Q \cap \Sigma^n| \leq q(n)$ for each $n$).

Now a function $g \in FP$ that on input $\varphi \in S$ yields a satisfying assignment for $\varphi$ can be computed as follows. Let $q'(n)$ denote the polynomial $q(n+c(n+1)) + 1$. Let $\varphi \in S$ be an input of length $n$. First assume that $n$ is sufficient large, i.e., $q'(n) \leq 2^n$. Let $w_1, \ldots, w_{q'(n)}$ denote the $q'(n)$ lexicographically first strings of $\Sigma^n$. Now simulate ‘in parallel’ the computations of $M'$ on input of $\text{pad}(\varphi, w_1)$,
... pad(ϕ, wq(n)), i.e. perform a simulation in stages, in stage \( i \) for each \( 1 \leq j \leq q'(n) \) simulate the \( i \)th step of the computation of \( M' \) on pad(ϕ, wj); notice that each stage \( i \) can be completed in time \( (q'(n) \cdot i)^2 \). Stop the simulation as soon as the first of those computations produces a satisfying assignment, say e.g. for pad(ϕ, wj). From this assignment obtain a satisfying assignment for \( \varphi \). For the finitely many input lengths \( n \) that do not satisfy \( q'(n) \leq 2^n \) determine a satisfying assignment by a table look-up.

This construction guarantees that for some polynomial \( r \) and every \( \varphi \in S \) we obtain a satisfying assignment of \( \varphi \) after at most

\[
r(n + \min\{\text{time}_{M'}(\text{pad}(\varphi, w_j)) \mid 1 \leq j \leq q'(n)\})
\]

steps. Observe further that the set \{ pad(ϕ, w_j) \mid 1 \leq j \leq q'(n) \} \subseteq \Sigma^{n+\epsilon(n+1)} \) is of cardinality \( q'(n) = q(n + \epsilon(n + 1)) + 1 \) and thus cannot be fully contained in \( Q \). Thus by assumption for some \( w_j \) \( M' \) produces a satisfying assignment of \( \text{pad}(\varphi, w_j) \) in time \( p(\text{pad}(\varphi, w_j))) \). This shows that the time needed for the above computation is bounded by a polynomial.

For the implication 2 \( \Rightarrow \) 3 let \( S \) be a set such that 2 is fulfilled. A suitable subset \( L \subseteq S \) is obtained by the following construction. Let \( M'_1, M'_2, \ldots \) be a (non effective) enumeration of the deterministic Turing machines that on input \( \varphi \in S \) produce a satisfying assignment of \( \varphi \).

Set \( n_0 = 0 \) and for \( k > 0 \) let \( n_k \) be the smallest number \( n > n_{k-1} \) such that the set

\[
S^n_k := \{ \varphi \in S \cap \Sigma^n \mid \text{time}_{M'_i}(\varphi) > n^k + k \text{ for all } i \leq k \}
\]

has cardinality greater than \( n^k + k \).

Observe that for each \( k \) there is such a number \( n_k \). If this were not the case for some \( k \), then for the least such \( k \) the set

\[
T = \{ \varphi \in S \mid \text{time}_{M'_i}(\varphi) > |\varphi|^k + k \text{ for all } i \leq k \}
\]

would be sparse (namely for each \( n > n_{k-1} \) we had \( ||T \cap \Sigma^n|| \leq n^k + k \)). However, this contradicts 2 if we let \( M' \) be a deterministic Turing machine that in parallel simulates the machines \( M'_1, \ldots, M'_k \) (notice that this parallel simulation is even possible without overhead since \( k \) is constant).

Now let \( L = \bigcup_{k>0} S^n_k \), and let \( f(n) = n^{k(n)} + k(n) \) where \( k(n) = \max\{k \mid n_k \leq n\} \).

Clearly \( f \) is super-polynomial, and \( L \) is non-sparse. To see that \( f \) and \( L \) also fulfill the last condition in 3 let \( M'_i \) be a deterministic Turing machine that on input \( \varphi \in S \) produces a satisfying assignment of \( \varphi \). By the construction, we have for each \( k \geq i \), and for each \( \varphi \in S^n_k \)

\[
\text{time}_{M'_i}(\varphi) > |\varphi|^k + k = f(|\varphi|).
\]

Thus for each \( \varphi \in L \) with \( |\varphi| \geq n_i \), \( \text{time}_{M'_i}(\varphi) > f(|\varphi|) \). For the proof of the implication 3 \( \Rightarrow \) 4, we observe that item 3 is the negation of item 4 from Theorem 16, whereas item 4 is the negation of item 2 in Theorem 19. Therefore, 3 implies 4 by an argument similar to the one given in the proof of implication 2 \( \Rightarrow \) 1 in Theorem 19. Finally, the implication 4 \( \Rightarrow \) 1 follows directly from Theorem 19. \( \square \)
6 On the Existence of P-optimal Proof Systems

In Theorem 18 it is observed that \( \text{sat} \) is p-optimal if and only if every optimal proof system is p-optimal. Although the assumption of the mere existence of a p-optimal proof system for SAT is presumably weaker than the assumption that \( \text{sat} \) is p-optimal, it is still equivalent to a quite similar statement, namely that any set with an optimal proof system has a p-optimal proof system. For the proof of this result we use the following observation from [28].

Lemma 21 ([28]). If \( L \) has a (p-)optimal proof system, and \( T \leq_{m}^{p} L \), then \( T \) has a (p-)optimal proof system.

Using this lemma we can prove the following ‘existentially quantified’ version of Theorem 18 from the previous section.

Theorem 22. The following statements are equivalent.

1. \( \text{SAT} \) has a p-optimal proof system.
2. Any language \( L \) that has an optimal proof system also has a p-optimal proof system.

Proof. Clearly, item 2 implies item 1, as \( \text{SAT} \) has an optimal proof system. To see the converse implication assume that \( \text{SAT} \) has a p-optimal proof system, and let \( L \) be an arbitrary nonempty language with an optimal proof system. Let \( T_{L} \) (cf. [28]) be the following language consisting of tuples \( \langle M, x, 0^{s} \rangle \) where \( M \) is a deterministic Turing transducer, \( s \geq 0 \), and \( x \in \Sigma^{*} \).

\[
T_{L} = \{ \langle M, x, 0^{s} \rangle \mid \text{time}_{M}(x) > s \text{ or } M(x) \in L \}.
\]

Notice that \( T_{L} \) is many-one reducible to \( L \). Hence, the assumption that there is an optimal proof system for \( L \) implies that \( T_{L} \) has an optimal proof system, say \( h \). Let

\[
S_{h} = \{ \langle \langle M, x, 0^{s} \rangle, 0^{l} \rangle \mid h \vdash_{\leq l} \langle M, x, 0^{s} \rangle \}.
\]

Clearly \( S_{h} \in \text{NP} \). Therefore by assumption there is a p-optimal proof system \( g \) for \( S_{h} \). Let now \( f \) be the following proof system.

\[
f(w) = \begin{cases} 
y & \text{if } g(w) = \langle \langle M, x, 0^{s} \rangle, 0^{l} \rangle, \\
\text{undefined} & \text{otherwise.}
\end{cases}
\]

First notice that \( y \in L \) if \( f(w) = y \). This is due to the fact that \( g(w) = \langle \langle M, x, 0^{s} \rangle, 0^{l} \rangle \) implies \( \langle \langle M, x, 0^{s} \rangle, 0^{l} \rangle \in S_{h} \) which in turn implies \( \langle M, x, 0^{s} \rangle \in T_{L} \). On the other hand, each \( y \in L \) is easily seen to have an \( f \)-proof, hence \( f \) is a proof system for \( L \).

We now show that \( f \) \( p \)-simulates every proof system \( f' \) for \( L \). Assume that \( f' \) is computed by the transducer \( M_{f'} \) in polynomial time \( p(n) \). Observe that \( \langle M_{f'}, x, 0^{p(|x|)} \rangle \in T_{L} \) for any \( x \in \Sigma^{*} \). Hence, one may define a proof system for \( T_{L} \) such that for any \( x \) the tuple \( \langle M_{f'}, x, 0^{p(|x|)} \rangle \) has the short proof \( 1x \). Consequently, due to the optimality of \( h \), there is a polynomial \( q \) such that
\langle M_f, x, 0^{p(|x|)} \rangle$ has an $h$-proof of size $\leq q(|x|)$. Now \langle \langle M_f, x, 0^{p(|x|)} \rangle, 0^{q(|x|)} \rangle \in S_h$ for any $x$, and one may define a proof system $g'$ for $S_h$ with $g'(1x) = \langle \langle M_f, x, 0^{p(|x|)} \rangle, 0^{q(|x|)} \rangle$ for any $x$. As $g$ is p-optimal, $g$ p-simulates $g'$, i.e., there is a function $t \in \text{FP}$ such that $g(t(1x)) = g'(1x) = \langle \langle M_f, x, 0^{p(|x|)} \rangle, 0^{q(|x|)} \rangle$. Observe now that $f(t(1x)) = f'(x)$ for any $x$. Hence $f$ p-simulates $f'$. \hfill $\square$

As shown in [28], the assumption that SAT and TAUT both have p-optimal proof systems implies that $\text{NP} \cap \text{coNP}$ has a many-one complete set. In fact, due to Theorem 22 it suffices to assume that SAT has a p-optimal proof system and TAUT only has an optimal proof system. Together with Proposition 3 we obtain:

**Corollary 23.** If SAT has a p-optimal and TAUT has an optimal proof system, then $\text{NP} \cap \text{coNP}$ has a many-one complete set, and $\text{NPSV}_t$ has a many-one complete function.

Next we show that a p-optimal proof system for SAT implies a complete function for the class $\text{NPMV}_t$. The proof uses ideas from [28].

**Theorem 24.** If SAT has a p-optimal proof system, then $\text{NPMV}_t$ has a many-one complete function.

*Proof.* Consider the NP-set $L = \{ \langle N, x, 0^s \rangle \mid \text{there is an accepting path of } N \text{ on input } x \text{ of length } \leq s \}$. If SAT has a p-optimal proof system, then due to Lemma 21 there is a p-optimal proof system $h$ for $L$. We show that the following function $g$ is complete for $\text{NPMV}_t$.

If the input is a tuple $u = \langle N, x, 0^s, w \rangle$ with the property that $h(w) = \langle N, x, 0^s \rangle$, then set-$g(u) = \{ y \mid y \text{ is an output of } N \text{ on an accepting path of length } \leq s \text{ on input } x \}$. Otherwise set-$g(u) = \{ \lambda \}$.

It is clear that $g$ is in $\text{NPMV}_t$. To see that $g$ is hard for $\text{NPMV}_t$ let $f \in \text{NPMV}_t$ be computed by a nondeterministic Turing machine $N_f$ with a polynomial time-bound $p$. It is easy to see that there is a proof system $h'$ for $L$ with $h'(1x) = \langle N_f, x, 0^{p(|x|)} \rangle$ for any $x$. As $h$ p-simulates $h'$ there is a function $t \in \text{FP}$ such that $h(t(1x)) = \langle N_f, x, 0^{p(|x|)} \rangle$ for any $x$. So, $x \mapsto \langle N_f, x, 0^{p(|x|)}, t(1x) \rangle$ is a many-one reduction from $f$ to $g$. \hfill $\square$

By Theorem 9 we obtain:

**Corollary 25.** If SAT has a p-optimal proof system, then there exists a strongly many-one complete disjoint coNP-pair.

In the following table we collect some of the implications proven in this section.

<table>
<thead>
<tr>
<th>Assumption</th>
<th>Consequence</th>
</tr>
</thead>
<tbody>
<tr>
<td>p-optimal proof system for SAT and optimal proof system for TAUT</td>
<td>complete set for $\text{NP} \cap \text{coNP}$ and complete function for $\text{NPSV}_t$</td>
</tr>
<tr>
<td>optimal proof system for TAUT</td>
<td>complete function for $\text{NP}^k \text{V}$, $k \geq 1$</td>
</tr>
<tr>
<td>p-optimal proof system for SAT</td>
<td>complete function for $\text{NPMV}_t$ and complete disjoint coNP-pair</td>
</tr>
</tbody>
</table>
7 Conclusion

We have shown that the assumption that certain proof systems are (p-)optimal can be used to derive collapse results. Also we presented some relations between completeness assumptions for different classes. It would be interesting to know whether these observations can be extended to further proof systems and promise classes.
