## Abstract

This paper reviews the worldwide growth of open-access (OA) repositories, December 2005 to December 2012, using data collected by the *OpenDOAR* project. It shows that initial repository development was focused on North America, Western Europe and Australasia, particularly the USA, UK, Germany and Australia. Soon after, Japan increased its repository numbers. Since 2010, other geographical areas and countries have seen repository growth, including East Asia (especially Taiwan), South America (especially Brazil) and Eastern Europe (especially Poland). During the whole period, countries such as France, Italy and Spain have maintained steady growth, whereas countries such as China and Russia have experienced relatively low levels of growth. Globally, repositories are predominantly institutional, multidisciplinary and English-language-based. They typically use open-source OAI-compliant repository software but remain immature in terms of explicit licensing arrangements. Whilst the size of repositories is difficult to assess accurately, the available data indicate that a small number of large repositories and a large number of small repositories make up the repository landscape. These trends and characteristics are analyzed using Innovation Diffusion Theory (IDT) building on previous studies. IDT is shown to provide a useful explanatory framework for understanding repository adoption at various levels: global, national, organizational and individual. Major factors affecting both the initial development of repositories and their take up by users are identified, including IT infrastructure, language, cultural factors, policy initiatives, awareness-raising activity and usage mandates. It is argued that mandates in particular are likely to play a crucial role in determining future repository development.

## Introduction

Open-access repositories of academic and research outputs are a significant development in the 21<sup>st</sup> century global research information environment. This paper reviews the worldwide growth of open-access (OA) repositories between December 2005 and December 2012. It also provides an overview of the main characteristics of the global repository infrastructure at the end of that period. It does so based on data collected during the seven-year period by the *OpenDOAR* project based in the Centre for Research Communications at the University of Nottingham, UK. In addition to outlining historic trends and current characteristics of the repository landscape, the paper also attempts to locate these developments within an overarching explanatory framework and discusses factors affecting possible future trajectories of repository development.

## Definitions

It is important initially to establish some definitions of key concepts, particularly ‘open access’ and ‘repositories’, since these form the basis of criteria for inclusion (and exclusion) in this study. ‘Open Access’ may be defined as where digital content is fully, freely, immediately and permanently available and can be viewed and reused with minimal restrictions (adapted from Pinfield, 2009, 166; with the explication that follows also adapted from the same source). The “digital content” referred to in the definition may take a number of different forms, including text, data and rich media (such as video). This content is “fully... available”, meaning that the content is accessible in its entirety rather than in a partial form (in the case of a journal article, for example, this would mean the full text is available and not just the abstract). It is also “freely... available”, meaning there are no costs charged at the point of access (although costs are of course incurred in generating and disseminating the content). The content is “immediately... available”, meaning there are no formal delays or embargoes on its availability. It is also “permanently... available”, meaning it is available on an ongoing basis so that it can be accessed and cited (usually involving a commitment to maintaining persistent access paths to as well as preservation of the content itself). The content may be “viewed” and also “reused with minimal restrictions”. Ability to view the content means it can be read (normally by humans), and ability to reuse the content means it can be copied, mined, processed, analyzed, indexed and redistributed (often by machines) with minimal rights restrictions.

The ideas characterized in this definition as ‘viewing’ and ‘reusing’ content are at the center of Suber’s (2008; 2012) important distinction between different “subspecies” of OA. After providing a brief definition of OA as, “digital, online, free of charge, and free of most copyright and licensing restrictions” (Suber, 2012, 4), Suber goes on to distinguish between, on the one hand, “Gratis open access” (which is free to view), and on the other hand, “Libre open access” (free to reuse and rework as well as view):

“Gratis OA is free of charge but not more free than that. Users must still seek permission to exceed fair use. Gratis OA removes price barriers but not permission barriers.

Libre OA is free of charge and also free of some copyright and licensing restrictions. Users have permission to exceed fair use, at least in certain ways...Libre OA removes price barriers and at least some permission barriers.” (Suber, 2012, 66)

The repositories recorded in *OpenDOAR* and included in this study comply in general terms with the definitions of open access provided by Pinfield and Suber, including both Gratis and Libre OA, although formerly-embargoed content is also permitted (see below) if it is made available on an OA repository.

The definition of ‘repository’ used here follows Pinfield (2009):

“A repository may be defined as a set of systems and services which facilitates the ingest, storage, management, retrieval, display, and reuse of digital objects. Repositories may be set up by institutions, subject communities, research funders, or other groups. They may provide access to a variety of digital objects, including peer-reviewed journal articles, book chapters, theses, datasets, learning objects, or rich media files.” (Pinfield, 2009, 165)

The key distinction often drawn in the literature in relation to academic and research repositories is between disciplinary repositories and institutional repositories (IRs) (Nicholas, Rowlands, Watkinson, Brown, & Jamali, 2012; Xia, 2008). The former contain the outputs of a particular subject community; well-known examples include arXiv for high-energy physics, RePEc for economics, and PubMed Central for biomedical and life sciences. The latter house the outputs of researchers and other research materials from a particular institution; early examples include Caltech in the USA and the University of Southampton in the UK. To these, Nicholas et al. (2012) also add ‘format’ repositories which contain particular types of files, such as e-theses, data sets or learning objects. There are also a small number of ‘governmental’ repositories managed by national governments and government-sponsored agencies, and ‘aggregating’ repositories which present content harvested from other sources. All of these categories of repositories are recorded in *OpenDOAR*: disciplinary, institutional, aggregating and governmental as ‘repository types’, with formats being recorded as different ‘content types’.

## Research context

Academic and research OA repositories have existed in various forms for more than two decades and have featured in the research and practitioner literature since then. As well as formally-published works, discussion around policy and practice in this area has taken place in email discussion lists, blogs and other more informal venues. Increasingly, the latest thinking (at least in provisional form) first appears in those places (as is increasingly the case in a variety of fields) and so it is important to take them into account in examining the research context.

Much of the early discussion centered on now well-established, disciplinary repositories such as arXiv, setup in August 1991 (for example, Ginsparg, 1997; Halpern & Lagoze, 1999; McKiernan,

2000; Pinfield, 2001). However, there has been a rapid growth of repositories more recently enabled to a significant degree by two technical developments between 2000 and 2003 which were widely discussed in the literature and other fora. The first of these was the development of the Open Archives Initiative Protocol for Metadata Harvesting (OAI PMH), an interoperability protocol for exchanging information between repositories (Lagoze & Sompel, 2003; Sompel & Lagoze, 2000). The second development (arising from the first) was the release of OAI-PMH-compliant open-source repository software, such as ePrints (Gutteridge, 2002) and DSpace (Smith et al., 2003). These developments meant that installing a repository became technically straightforward and therefore facilitated the growth of repository numbers, including the development of institutional repositories (Crow, 2002; Lynch, 2003). Repository growth began to accelerate in the middle of the first decade of the 21<sup>st</sup> Century on the foundation of these two developments and *OpenDOAR* (Directory of Open Access Repositories) was set up to track that growth.

During this period, there has also been a maturing of new models of scholarly communication particularly associated with open access. Many OA repositories began to be designed to support so-called ‘Green’ OA: the depositing in repositories of research papers which have been or are expected to be published in peer-review journals, often involving authors ‘self-archiving’ their own outputs (Suber, 2012, 52-65; Björk, Laakso, Welling, & Paetau, 2013). There is now a large literature on OA repositories, most of it focusing in particular on their role in supporting Green OA as a form of scholarly communication. Studies cover a wide range of issues including user attitudes and behaviors (including Kim, 2010), different disciplinary positions (such as Xia, 2007), changing roles for librarians (including Walters, 2007), and legal issues (for example Hanlon & Ramirez, 2011). There are also various practice-based case studies (such as Connell, 2011) and guides, particularly on institutional repositories (for example Nabe, 2009). Some research has analyzed growth trends and key characteristics of repositories often using *OpenDOAR* data. A number of studies have focused on IRs in specific geographical areas, such as Canada (Shearer, 2006), Zimbabwe (Nyambi & Maynard, 2012), India (Tripathi & Jeevan, 2011; Sawant, 2011), or Asian countries in general (Nazim & Mukherjee, 2011). Other focuses have been on subject-based repositories for particular disciplines, such as on Chemistry (Warr, 2003) and Computer Science and IT (Bhat, 2010). There is also a significant literature on format repositories, particularly repositories for theses (an overview has been provided by Yiotis, 2008) and learning objects (a quantitative study of the global infrastructure is provided by Ochoa & Duval, 2009). All of these areas of the literature contribute to discussion on the (potential) role of OA repositories in a developing scholarly communication infrastructure.

In the discussion, Green OA is often set against ‘Gold’ OA, open-access publication in journals. For example, Stevan Harnad, a well-known Green advocate, following the new emphasis in UK policy on Gold OA in 2012, referred rhetorically in his blog and email discussion lists to “fools Gold”, criticizing what he saw as a “Gold Rush”, and calling for a greater emphasis on Green OA (for example, Harnad, n.d.). However, as Pinfield (2009) notes, repositories and journals are not necessarily mutually exclusive OA solutions. For example, some large-scale repositories, notably PubMed Central, have been set up primarily to house material first published in an OA form by journals. Such repositories are covered by the *OpenDOAR* database along with others.

Running through much of the literature and other fora is an awareness that even at a time of growth of repository numbers there has been relatively slow take-up of *use* of repositories by researchers (in terms of contributing and using content) in most areas (with repositories such as arXiv and PubMed Central being exceptions). A large amount of the practitioner output on repositories (particularly IRs) focuses on this issue (for example, Davis & Connolly, 2007; Lawal, 2002), and includes case studies of awareness-raising and advocacy programs aimed at encouraging researcher engagement with repositories (for example, Buehler, 2013; Foster & Gibbons, 2005; Palmer, Tefteau, & Newton, 2008). Related to this, there has also been extensive discussion on the development of policy mandates by institutions, funders or other agencies as a means of increasing usage (for example Kennan, 2011; Lariviere, Gingras, Carr, Brody, & Harnad, 2012; Pinfield, 2005).

The research literature includes various analyses of repository development deploying different theoretical models particularly focusing on the issue of the usage levels of individual researchers. Kim (2010; 2011) uses Socio-Technical Interaction Networks (STIN) and Social Exchange Theory to study faculty self-archiving practices. Using a combination of qualitative and quantitative data from surveys and interviews, she identifies a number of factors which have implications for repository implementation. She concludes that, “Faculty are motivated by OA advantages to users, disciplinary norms, and no negative influence on academic reward. However, barriers to self archiving – concerns about copyright, extra time and effort, technical ability, and age – imply the provision of services to assist faculty with copyright management, and with technical and logistical issues, could encourage higher rates of self archiving” (Kim, 2010, 1909).

Another theoretical framework usefully deployed to explain repository adoption by individual researchers is the Unified Theory of Acceptance and Use of Technology (UTAUT). First developed by Venkatesh, Morris, Davis, & Davis, (2003), this theory has been used by Mann, von Walter, Hess, & Wigand (2009), and Dulle & Minishi-Majanja (2011) whose quantitative studies demonstrate the particular importance of “Performance Expectancy”, “the degree to which an individual believes that using the system will help him or her attain gains in job performance” (Venkatesh et al., 2003, 447). Other important factors, including attitude to OA, awareness of OA developments, and expected effort of using the technology are also identified as significant by Dulle & Minishi-Majanja (2011). However, as Björk et al. (2013) observe, the major weakness of these studies is that they conflate Green and Gold OA in their analyses. A more recent study, Singeh, Abrizah, & Karim (2013), casts some doubt on the utility of UTAUT in this context since the authors do not find a correlation between UTAUT determinants and use behavior associated with repositories. However, they still recommend further research to test their conclusions, since, as they acknowledge, theirs is a small-scale study and it *does* at least find a positive relationship between the determinants. All of the studies make practical recommendations around improving researcher awareness and considering the potential of OA policy mandates.

A final theoretical model used to explain repository development is Innovation Diffusion Theory (IDT). This has been deployed by Jones, Andrew, & MacColl (2006) in a practitioner context to frame a discussion of the development of an institutional-level advocacy campaign aimed at promoting the use of an institutional repository. IDT has also been used at a very different level by Xia (2012): to explain different adoption patterns of both OA journals and repositories worldwide. His analysis

usefully incorporates discussion of technological, cultural and policy factors which influence varying take-up globally. These studies using IDT between them illustrate a particular strength of Diffusion Theory in that it can be used to explain adoption characteristics at a number of levels, including local level (taking into account the behaviors of individual actors) and global level (taking into account large-scale cultural and technological trends). It is deployed later in this paper to provide an explanatory framework for the data presented which relate to the levels already described but also, crucially, to organizational-level adoption.

This paper aims to provide a high level-analysis of the entire OA repository population worldwide, including all repository types (disciplinary, institutional, format and others). It reviews the major growth trends of repositories across different continents and countries and also analyses repositories' current characteristics. It makes a number of observations about the contribution to and usage of repositories within research communities. Based on the data presented, it goes on to discuss various factors which have affected repository development to date and are likely to impact on further growth in the future.

## Data collection

The data analyzed here were gathered as part of the *OpenDOAR* (Directory of Open Access Repositories) project based at the University of Nottingham, UK, carried out initially in partnership with Lund University, Sweden. *OpenDOAR* was set up in 2005 to create “an authoritative directory of academic open access repositories” throughout the world (OpenDOAR, n.d.-a). It began collecting data in that year which were used as the basis of the *OpenDOAR* web directory, launched in December 2005 and available since then. The records are periodically reviewed, updated and augmented in the database and therefore the online service provides an up-to-date snapshot of the worldwide academic repository landscape.

The *OpenDOAR* service is now used as an important source for data for research on OA developments (for example, Björk et al., 2013), OA Advocacy (for example, Morrison, 2012), and also, via its application programming interface (API), as a data feed for other OA-related online services (including: BASE, CORE, Institutional Repository Search, Open Access Tracker, OpenAIRE, OpenDepot, Repository 66, and ROAR). Because of its widespread use, it is useful to provide here some detail on its design and to review the repository growth trends and characteristics it records.

An *OpenDOAR* online public record consists of the following:

- Organisation: the official title and country of origin of the organization(s) responsible for the repository
- Description: a free text description of the repository and its services
- OAI PMH: the Base URL for the Open Archives Initiative Protocol for Metadata Harvesting
- Software: the software used as the basis for the repository, when known

- Size: the number of records in the repository (updated every 2-4 weeks)
- Subjects: broad subject description (using a controlled vocabulary based on the broad categories in the Library of Congress classification scheme) or “multidisciplinary” if covering a wide range of subjects
- Content: content types based on controlled vocabulary descriptions of “articles”, “conferences”, “books”, “theses”, “learning objects” and other major formats
- Languages: principal languages present in the repositories content
- Policies: descriptions of submission and reuse rights for metadata and full items, and content on preservation policies where available, using standardized vocabulary
- Remarks: free text field providing any other additional information, for example on partnerships or membership of consortia
- *OpenDOAR* ID: the unique record number within the *OpenDOAR* database

These key data points are the basis of this study. Added to them are other data recorded in *OpenDOAR*, including interoperability protocols deployed by repositories and geographical coordinates of systems.

*OpenDOAR* records are, for the most part, created and maintained manually, rather than by automated harvesting, in order to ensure a high level of quality. The *OpenDOAR* website explains this approach:

“As part of this quality assurance, *OpenDOAR* administrators carry out a detailed investigation of each site, to ensure that the site is both accessible and provides access to full-text content, without the need for a subscription or registration.” (*OpenDOAR*, n.d.-b)

This manual record creation is augmented by regular automated checks on each repository site recorded in the database to ensure it is still available and also to enable the update of the “Size” field in *OpenDOAR*. Repositories which prove to be inaccessible to the *OpenDOAR* robot are then rechecked manually and any necessary changes to the Directory made, including the removal of records for repositories no longer available. It normally takes between one and two weeks from initial suggestion or discovery of a repository to its inclusion in the *OpenDOAR* database. This has changed little since the first year of *OpenDOAR*’s release and therefore the database administrators express confidence that *OpenDOAR* has been a relatively accurate and up-to-date picture of the repository landscape, certainly since it became fully established in the fourth quarter of 2006.

Potential repositories for inclusion in *OpenDOAR* are identified in various ways, including proactive searching by *OpenDOAR* staff and checking other sources such as registrations on the Open Archives Initiative website (repositories included in *OpenDOAR* do not necessarily have to be OAI-PMH-compliant but most are). In more recent years, many of the new records have been added as a result of managers of recently-launched repositories applying to *OpenDOAR* to register their service. This community-based participation in *OpenDOAR*, also seen in suggested updates to records, has undoubtedly played an important role in maintaining the currency of the database. On occasions, some records have been added to *OpenDOAR* in batches in order to update the database rapidly. Although this is relatively rare, it applies to some repositories particularly in non-English-language-speaking countries, such as Japan and Poland. This pragmatic approach to keeping the database up-to-

date as possible reflects the fact that it is designed *primarily* to be an up-to-date directory at any given time rather than archive of historic trends and it is illustrated in some of the data presented below.

The criteria for inclusion in the database are specified on the *OpenDOAR* website which summarizes its approach as aiming to,

“...collect and provide information solely on sites that wholly embrace the concept of open access to full text resources that are of use to academic researchers. Thus sites where any form of access control prevents immediate access are not included; likewise sites that consist of metadata records only are also declined.” (OpenDOAR, n.d.-a)

This pragmatic definition of ‘open access’, encompassing both Gratis and Libre OA and also including previously-embargoed content, allows for the inclusion of the widest possible range of OA repositories supporting the research community. It does, however, exclude repositories which require user registration or application for content, conditions which are typical of many data repositories. Repositories must contain a proportion of full-text or other full-content files, but the published criteria do allow for some metadata-only records in repositories:

“Repositories where both full-text and metadata entries are available in an open access manner, may be included, where all other inclusion criteria are met.” (OpenDOAR, n.d.-b)

Thus the records listed in the database in the “Size” field may contain a combination of full-text and other fully-open resources, plus metadata-only records. *OpenDOAR* does, however, reject a significant proportion of the repositories suggested for inclusion, one reason for which may be a repository entirely populated with metadata-only records:

“*OpenDOAR* currently rejects about one quarter of the suggestions it receives. Rejected sites are primarily spam, metadata only repositories, duplicate suggestions or open access journals.” (OpenDOAR, n.d.-b)

The last of these, open-access journals, are included in *OpenDOAR*’s ‘sister’ service, DOAJ (Directory of Open Access Journals) and are therefore not duplicated in *OpenDOAR*. Most repositories listed in *OpenDOAR* contain academic papers (‘e-prints’) – the service was originally conceived as registry of e-print repositories. However, a minority of repositories also included in *OpenDOAR* contain a wide variety of other formats such as data sets, learning objects, and images.

The approach taken by *OpenDOAR* differs from other available directories of OA repositories. For example, ROAR (Registry of Open Access Repositories) is based on automatic harvesting (including records derived from *OpenDOAR* itself) rather than manual record creation. One major advantage of the ROAR approach, it might be argued, is immediacy: regular automated harvesting means there are no delays in record creation. In contrast, the *OpenDOAR* team has had to work hard to ensure that its manual record creation is timely in establishing its processes (although it has a good record in doing so). However, a major disadvantage of the entirely automated approach is the fact that it tends to pick up a significant number of ‘invalid’ sites, including experimental implementations which have few records or those with metadata-only entries. Such sites are rejected by *OpenDOAR*. As a result,

ROAR tends to have larger numbers of repositories listed in its directory at any one time than *OpenDOAR* (a fact observed with partial explanation by Morrison, 2012).

As well as counts of repositories, *OpenDOAR* also differs significantly from ROAR in the way it counts items *within* each repository. Repository sizes in ROAR are determined using the OAI PMH harvesting of ‘record counts’. However, testing carried out by *OpenDOAR* has found this to be unreliable and has therefore developed a set of alternative automated counting methods which testing has shown to be more accurate. A total of 12 different methods have been developed and applied selectively to different repositories depending on a number of factors including, for example, the software that a repository uses (Millington, 2013). For each repository listed in *OpenDOAR*, an initial assessment is made of which counting method is likely to yield most accurate results and, following tests where necessary, this preferred method is then used to harvest data on record counts from that repository. Consequently, *OpenDOAR* and ROAR, using different approaches to record counts, usually record different sizes for any given repository.

The data analyzed here were extracted from the *OpenDOAR* database and cover the period December 2005 to December 2012. Data on the historic growth of the database over that period were provided by the Centre for Research Communications on 7 January 2013. A snapshot of the entire database was also taken on 19 December 2012 downloaded through the publicly-available *OpenDOAR* API. In addition, comparable detailed snapshot data from 15 February 2008 were also available allowing some comparisons to be made. The data were processed and analyzed using SPSS and Excel.

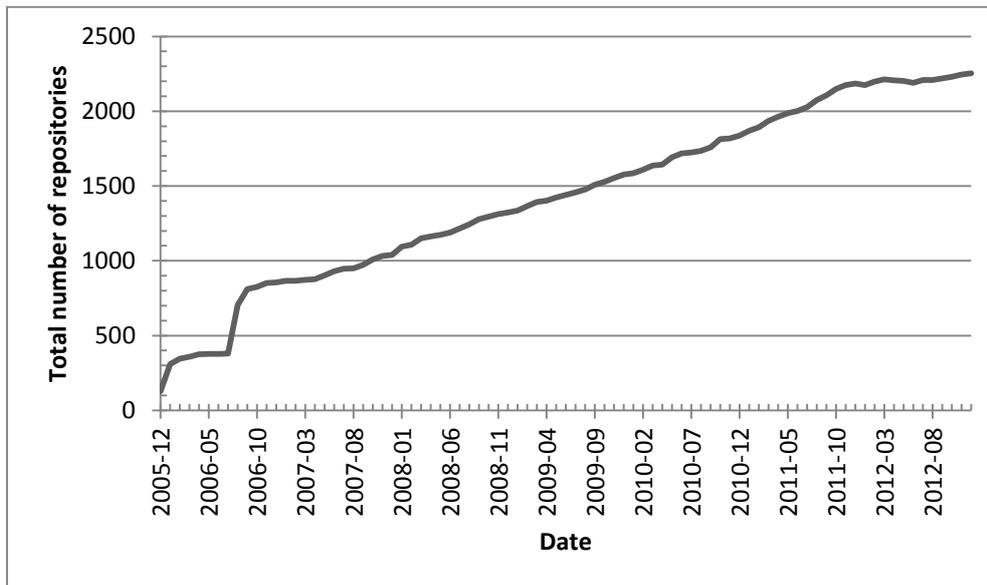

## Results

### *Worldwide repository growth*

Overall, the total number of repositories in *OpenDOAR* grew from 128 in December 2005 to 2253 in December 2012 (see Figure 1). This represents a 1660% increase over the period. However, the rate of growth was not entirely consistent over that time: there was very rapid growth in the first year (from 128 to 855 repositories, between December 2005 and December 2006) and a slowing down of growth in the final year (from 2185 to 2251, between December 2011 and December 2012).

In relation to the first of these periods, it may be commented that this time (2005 to 2006) was certainly one of rapid growth in repository numbers; however, other factors may also be important in explaining the changes. The growth in numbers is to a certain extent undoubtedly a function of *OpenDOAR* service development and consolidation during its first year of operation. In particular, the step change noticeable between July and August 2006 (from 379 repositories to 704), preceded by a three-month plateau, is certainly an artifact of the technical development of the service during that time. Between May and July 2006 *OpenDOAR* underwent a technical infrastructure upgrade as part of its move from being a pilot to becoming a full production service. During those three months, records for repositories were created off-line in a separate database and batch uploaded into the new

upgraded service during August and September 2006. This accounts for much of the rapid rise in record numbers during that period.

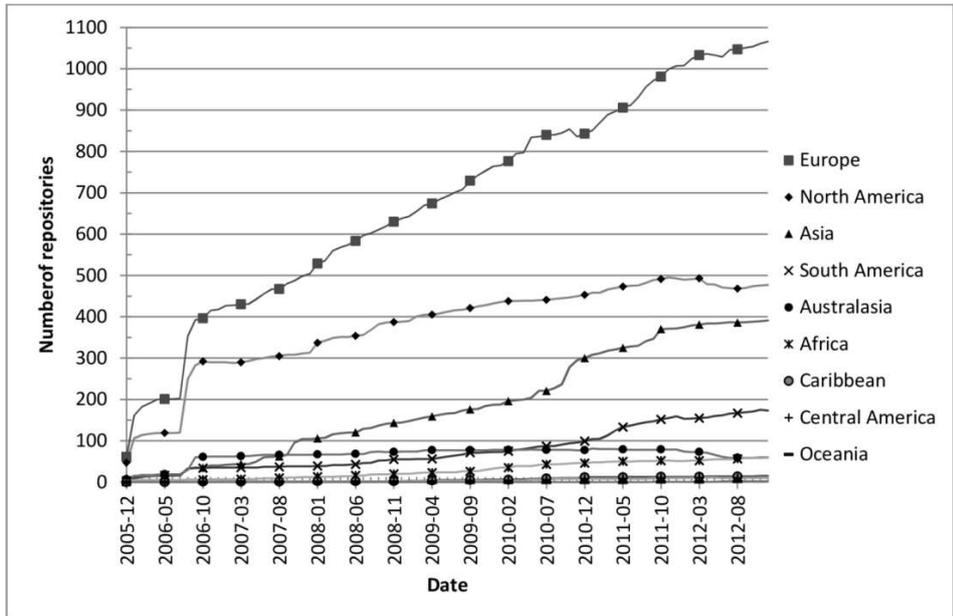

**Figure 1. Overall growth of repositories in *OpenDOAR*, December 2005 to December 2012.**

However, the apparent slowing down of growth in the final year is more difficult to account for. It is likely to be attributable to a complex set of factors, some to do with repository growth itself, others to do with the management of the *OpenDOAR* database. Examples of the former may be possible repository saturation in certain countries and rationalization of multiple repositories into single systems (both discussed below). An example of the latter is the systematic deletion of ‘dead’ repository records, a project that took place in accelerated form during 2012.

### *Geographical distribution*

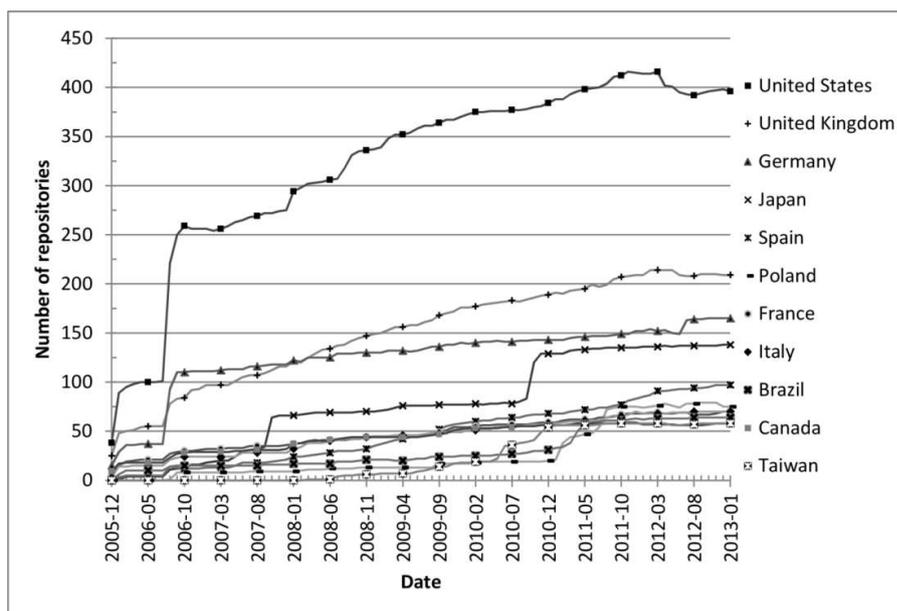

Figure 2 illustrates growth of repositories by continent between December 2005 and December 2012. *OpenDOAR* uses ISO-3166 country attributions published by the International Organization for Standardization (ISO, n.d.) and associates them with nine continent designations: Africa, Asia, Europe, North America, Oceania, South America and also Australasia, the Caribbean and Central America (these last three areas are sometimes controversially subsumed within larger continents but are kept separate in *OpenDOAR*).

**Figure 2. Growth of repositories by continent, December 2005 to December 2012.**

The data show Europe has consistently had a larger number of repositories than other continents, with the gap growing between it and North America (which shows shallower growth) during the period. Asia has shown a steeper growth pattern since late 2010, albeit at a lower level than Europe or North America. Africa has experienced low-level growth throughout the period. Unusually, Australasia is notable as having experienced a decline in the number of repositories since the beginning of 2011 (from 81 in January 2011 to 60 in December 2012). This is likely to be attributable to the closure of the Australasian Digital Theses (ADT) program in 2010, resulting in Australian universities merging their theses collections with their main IRs over the following year (Darby & Dyer, 2011).

More detail is shown in Figure 3 which illustrates the growth of repositories in the ‘top 10’ countries (‘top 10’ in terms of numbers of repositories as at December 2012). The data show the USA to have had the largest number of repositories for the entire period covered by *OpenDOAR*, followed by the UK and Germany. Germany’s growth trend has been flatter than the UK’s, although the UK’s growth has plateaued since the end of 2011. This plateauing raises the important issue of ‘saturation’, particularly for institutional repositories. It might be argued, for example, that with 209 repositories, most of which are institutional (see below), the UK is reaching a point where it is unlikely there will be significant further growth in the number of repositories since this figure reflects closely the number of major higher education and research institutions in the country.

**Figure 3. Growth of repositories by country (Top 10).**

Compared with countries such as Spain, France and Italy which have seen steady growth throughout the period covered by *OpenDOAR*, other countries in the top 10 have seen an acceleration of growth later in the period, notably Taiwan (since mid-2010), and Brazil and Poland (since the beginning of 2011). Japan has clearly experienced growth from an earlier period (from 2006) onwards; however, it does follow a somewhat anomalous growth pattern, including two major step changes in growth. This is an artifact based on the data collection method for this and a small number of other non-English-language speaking countries which are derived from available English-language listings of repositories. In the case of Japan, data in *OpenDOAR* are derived from the Japanese National Institute of Informatics listing of repositories (NII, n.d.), and reflects at least to some extent their update patterns.

A number of countries show relatively low levels of growth in repository numbers during the period studied. For example, China, in December 2006 was recorded as having 2 repositories; by December 2012, this number had risen to only 33. Over the same period, repository numbers in the Russian Federation rose from 1 to just 12.

Overall, between December 2006 and December 2012, the number of different countries in the *OpenDOAR* database rose from 48 to 102. Tables 1 and 2 provide a comparison between the ‘top 10’ countries by repository numbers in December 2006 and December 2012. Table 1 shows the top 10 countries in 2006 and is comprised of countries in North America, Western Europe, plus Australia and Japan. Table 2 shows the 2012 top 11 countries (Canada and Taiwan are equal tenth) and illustrates the emergence of countries from Eastern Europe (Poland), South America (Brazil) and Asia (Taiwan). Also Spain, not previously in the top 10, has developed a large number of repositories compared with many other countries in Western Europe. France and Italy have remained in the top 10 with consistent development over the period. The Netherlands was initially in the top 10, but with an early repository

development program and only a relatively small number of higher education institutions, seems to have reached saturation point early and therefore has been overtaken by countries with larger numbers of institutions.

<i>Country</i>	<i>Number of repositories</i>
United States	256
Germany	111
United Kingdom	93
Australia	52
Netherlands	44
France	31
Canada	29
Sweden	29
Italy	24
Japan	16

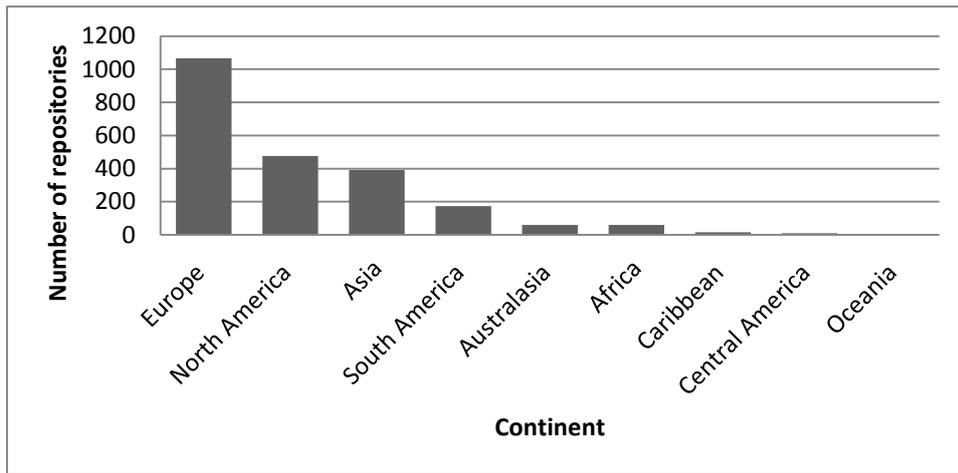

**Table 1. Top 10 countries by repository numbers, December 2006.**

<i>Country</i>	<i>Number of repositories</i>
United States	398
United Kingdom	209
Germany	165
Japan	138
Spain	97
Poland	75
France	70
Italy	70
Brazil	64
Canada	58
Taiwan	58

**Table 2. Top 11 countries by repository numbers, December 2012.**

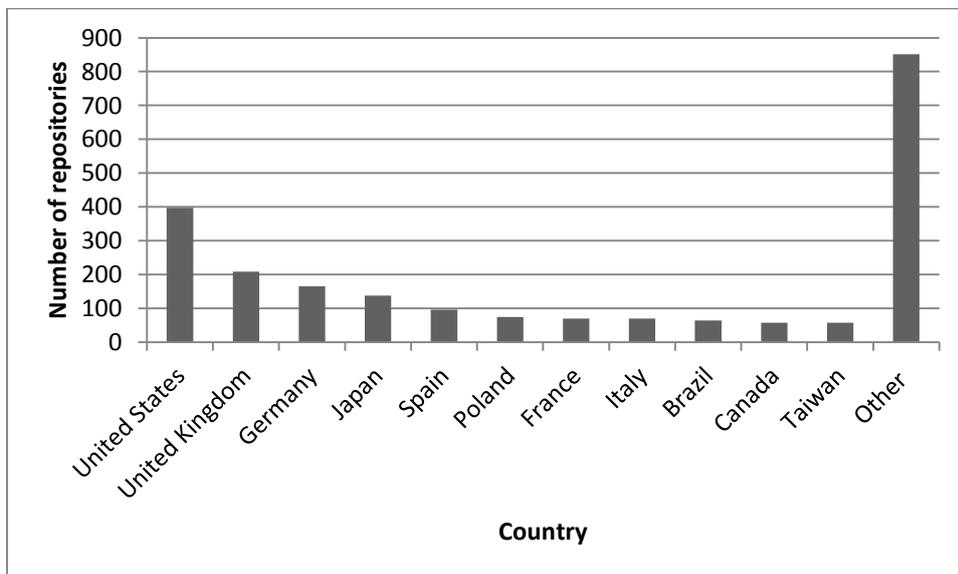

An interesting feature between the two tables is that the number of repositories in the top country in 2006 (US, n=256) is 16 times that of the number of repositories in the tenth country (Japan, n=16), whereas in 2012 this difference in the number of repositories between the top country and the tenth country was less than sevenfold (6.98). This is indicative of the growth in repository numbers outside of the relatively small group of early adopters.

The longitudinal data are complemented by the data collected on repositories in December 2012 derived from a snapshot of the entire *OpenDOAR* database at that time. These show in detail the distribution of repositories by continent and country. Figure 4 presents the data by continent, showing Europe to have the largest number of repositories (1066; 47%), followed by North America (477; 21%), Asia (389; 17%), and South America (391; 8%).

**Figure 4. Repositories by continent, December 2012.**

Figure 5, repositories by country in December 2012, shows the extent to which the US has a noticeably larger number of repositories than other countries (398; 18% of the total). The US is followed by the UK (209; 9%), Germany (165; 7%) and Japan (138; 6%). These and the other top 11 countries (with Canada and Taiwan equal tenth with 58 repositories each) are responsible for a total of 1402 repositories, 62% of all repositories worldwide.

**Figure 5. Repositories by country, December 2012.**

The data therefore show a pattern of repository development initially concentrated in North America, Western Europe and Australasia in the middle of the first decade of the 21<sup>st</sup> century, with Japan also showing significant development soon after. Growth continued in those locations but also occurred in

other areas, notably Eastern Europe (particularly Poland), South America (particularly Brazil) and East Asia (particularly Taiwan). The worldwide distribution of repositories in December 2012 is illustrated in Figure 6 based on data where the *OpenDOAR* record includes coordinates (present in 2212 of the 2253 records).

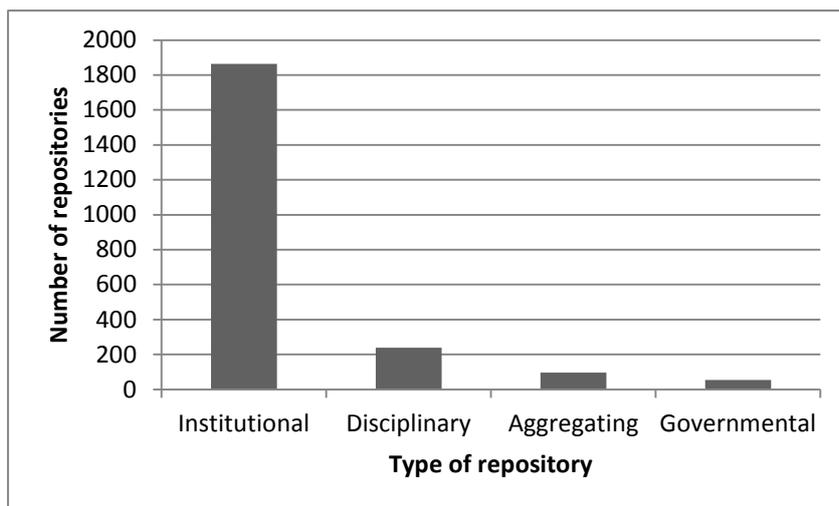

**Figure 6. Map of repositories worldwide, December 2012.**

### *Repository characteristics*

A number of key characteristics of the repository infrastructure in December 2012 can be identified from the *OpenDOAR* data. These include repository ‘type’ (institutional, disciplinary, etc.), subject coverage (multidisciplinary or subject specific), content type (journal articles, theses etc.), language and size. These data can be compared with those available from February 2008, which include a similar level of detail on repository characteristics, in order to identify any major changes since that time.

With regard to repository type, the vast majority of repositories worldwide are classified as ‘institutional’ by *OpenDOAR* (Figure 7). Institutional repositories account for 1864 of the global 2253 repositories, 83% of the total. Disciplinary repositories are the other major category, but these still only account for 11% (238) of the total. There were also 96 aggregating repositories (4% of the total) and 55 governmental repositories (2% of the total). These proportions have changed little since February 2008. Then, of the 1074 repositories, 800 (80%) were institutional, and 143 (13%) disciplinary. In addition, there were 5% aggregating and 2% governmental repositories.

**Figure 7. Repository types, December 2012.**

A total of 1857 different organizations are listed in the database as supporting repositories in December 2012. Data presented by Björk et al. (2013) suggest that these organizations include a large proportion of the “most productive” research institutions worldwide by publications. Using *OpenDOAR* and *ROAR* data on institutional repositories, they made comparisons with the global league table of institutions produced by *SCImago*. They concluded, “Of the 148 most productive institutions, 82% had at least one institutional repository for the purpose of collecting, preserving and disseminating the intellectual output of the institution. The count of scientific documents for those institutions amounts to 3,620,234 (85%), which also gives some hints on the mass of authors given the possibility to self-archive in their affiliated institution’s repositories.” (Björk et al., 2013, 21). This analysis illustrates the potential of the repository infrastructure now established worldwide.

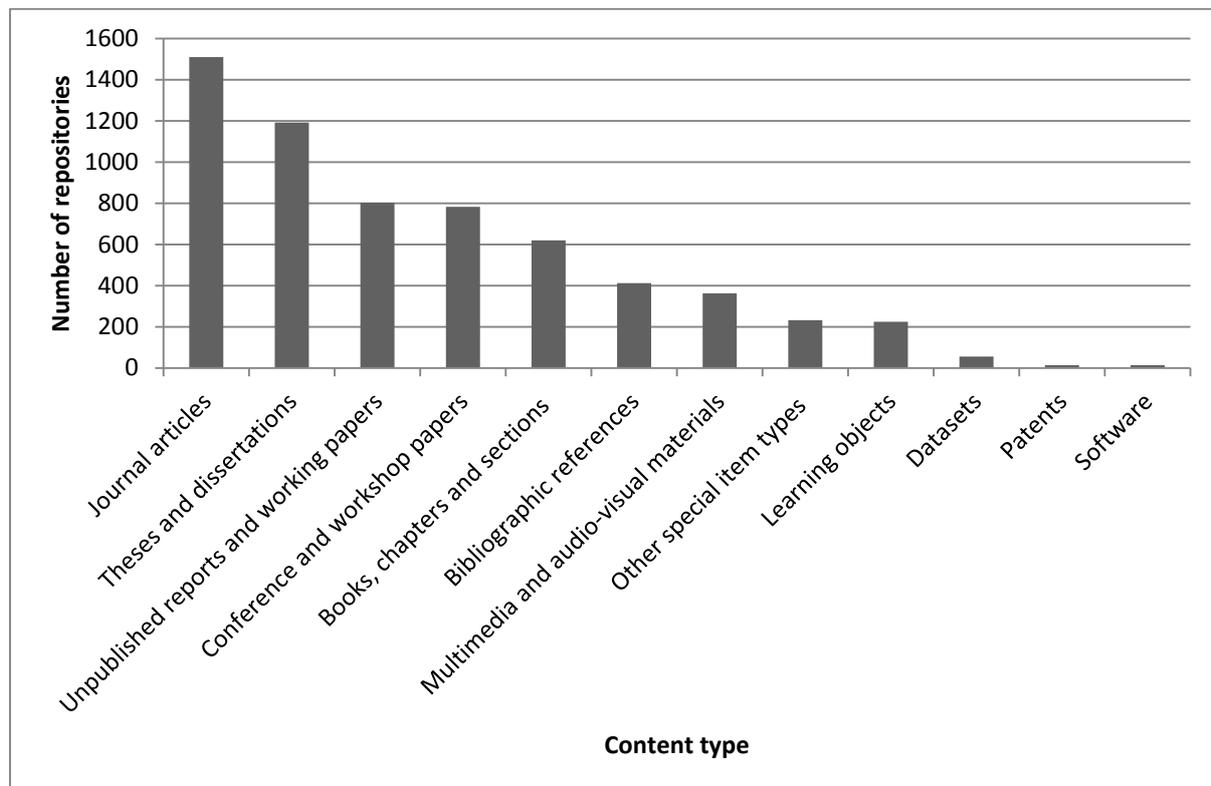

Most of the repositories are multidisciplinary in coverage, something which is to be expected if they are institutionally focused. Table 3 shows multidisciplinary repositories represent 1390 (62%) of the repositories worldwide. Where repositories have a specific identifiable subject coverage (rather than being multidisciplinary), the subjects are recorded in *OpenDOAR*. There are a wide range of subjects listed without any major subject area dominating: all are below 10% of the total number of repositories. Multidisciplinary repositories have increased their share of the overall repository infrastructure since February 2008. Then multidisciplinary repositories constituted 54% of the whole (581 of the 1074), although similarly, no other subject category exceeded 10%.

<i>Subject</i>	<i>Frequency</i>	<i>Percentage</i>
Multidisciplinary	1390	61.7
Health and medicine	210	9.3
History and archaeology	179	7.9
Business and economics	149	6.6
Law and politics	146	6.5
Technology general	145	6.4
Science general	144	6.4
Computers and IT	124	5.5
Education	123	5.5
Geography and regional studies	123	5.5
Social sciences general	119	5.3
Biology and biochemistry	112	5
Ecology and environment	107	4.7
Library and information science	97	4.3
Arts and humanities general	95	4.2
Agriculture, food and veterinary	86	3.8
Philosophy and religion	85	3.8
Language and literature	84	3.7
Mathematics and statistics	77	3.4
Fine and performing arts	75	3.3
Management and planning	73	3.2
Physics and astronomy	70	3.1
Chemistry and chemical technology	69	3.1
Psychology	54	2.4
Earth and planetary sciences	45	2
Mechanical engineering and materials	44	2
Architecture	36	1.6
Electrical and electronic engineering	35	1.6
Civil engineering	27	1.2

**Table 3. Repositories by subject, December 2012.**

As Figure 8 shows, the most common content type for repositories listed in *OpenDOAR* is journal articles: 1509 (67%) of repositories include this content type. Other content types are unpublished reports and working papers, including pre-refereed versions of articles (in 802; 36% of repositories), conference and workshop papers (783; 35%), and books, chapters and sections of works (619; 31%). There are a number of other types, such as specific formats including learning objects and datasets, in a smaller number of repositories. Most repositories then include several content types which clearly

support the scholarly communication process in various ways. These proportions have not markedly changed since 2008.

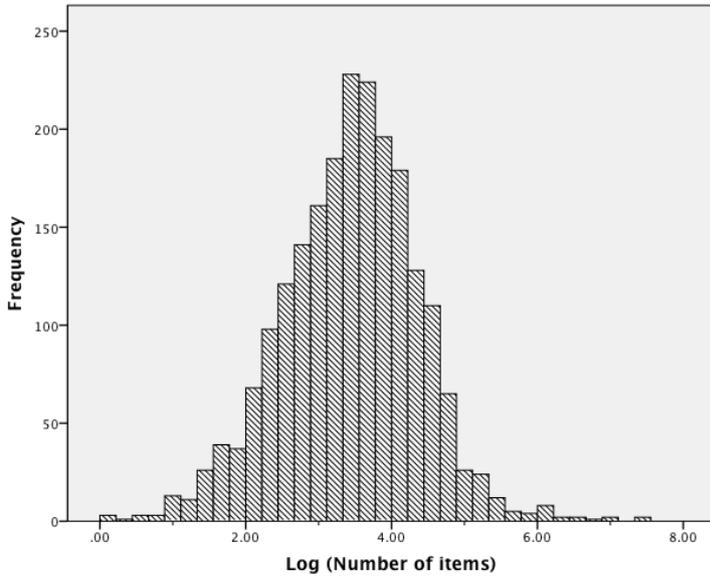

**Figure 8. Repository content types, December 2012.**

Language is also an important characteristic of repositories identified in *OpenDOAR*. In December 2012, *OpenDOAR* listed repositories containing resources in 57 languages. English was the most common language. 1595 repositories (71%) included English-language material. The predominance of English partly reflects the native-language of host countries of repositories but also no doubt reflects the position of the English language as the *lingua franca* of scholarship particularly in the science, technology and medicine domains (Tardy, 2004). There are, however, other common languages represented in repositories, also reflecting the countries of origin: Spanish (263, 11%), German (193, 8%) and Japanese (139, 6%). There are materials in a large number of languages included in a small number of repositories (10 or fewer). Repositories containing non-English language materials have increased as a proportion of the whole since February 2008. Of the 1072 repositories on *OpenDOAR* in February 2008, 85% (917) of them included English compared with 71% of the total in December 2012 evidencing repository development outside of English-speaking countries in the time since early 2008.

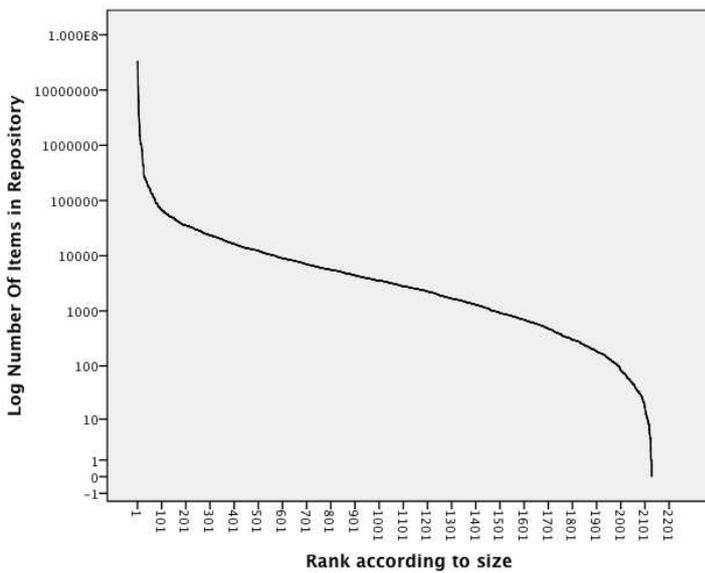

<i>Language</i>	<i>Frequency</i>	<i>Percentage</i>
English	1608	71.4
Spanish	263	11.7
German	196	8.7
Japanese	140	6.2
French	129	5.7
Portuguese	114	5.1
Chinese	97	4.3
Polish	74	3.3
Italian	72	3.2
Norwegian	49	2.2

**Table 4. Top 10 languages in repositories worldwide, December 2012.**

A particularly controversial issue associated with repositories is their size. The largest repositories contain millions of separate items. For example, one of the largest repositories in *OpenDOAR*, Europe PubMed Central, contains 29,100,000. However, the vast majority of repositories are relatively small. Of the 2129 repositories in *OpenDOAR* with “size” data recorded, only 74 of them have more than 100,000 items, and 570, more than 10,000 items. Whilst the mean average of items in repositories is 66,526, the median number is only 3093. Figure 9 shows a histogram for the size of repositories in *OpenDOAR* on a logarithmic scale and Figure 10 shows the same data according to rank order of size. These illustrate the distribution of repository size across the entire population. The data show, in simple terms, that there are a very small number of large repositories (i.e., with more than a million items) and a large number of small repositories (with between 100 and 100,000 items) which make up the global repository landscape. There are also a low number of very small repositories, with less than 6.6% of the population having 100 or fewer items. This is not surprising given that initial repository deployment may often tend to be associated with deposit of an early tranche of materials and organizations may not invest in initiating repository deployment without such a corpus being available.

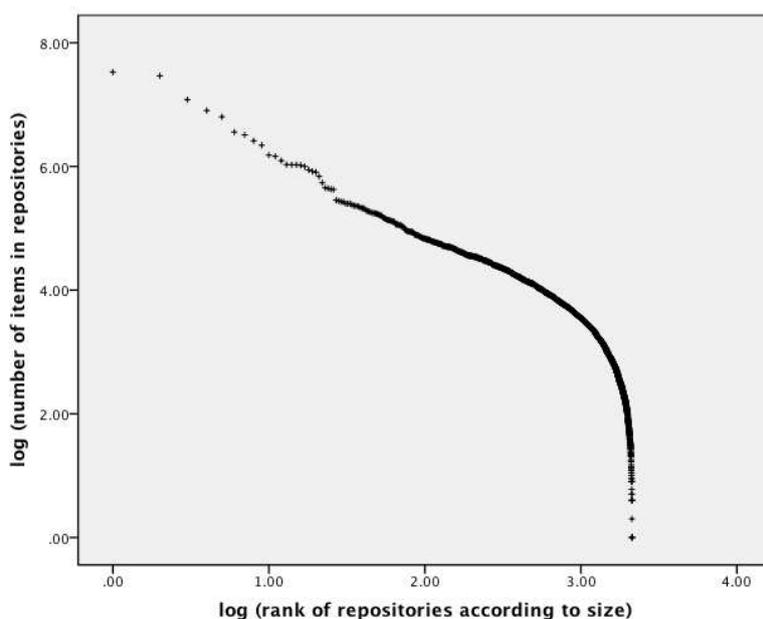

**Figure 9. Histogram of repository size, December 2012, on a logarithmic scale.**

**Figure 10. Repository size, December 2012, on a logarithmic scale, according to rank order.**

Figure 11 shows the number of items contained in repositories on a logarithmic scale against the log rank of the repositories and demonstrates a power law distribution over the bulk of the  $x$ -axis, with the relationship breaking down for the lower ranked repositories.

**Figure 11. Repository size according to rank, (December 2012) on logarithmic scales.**

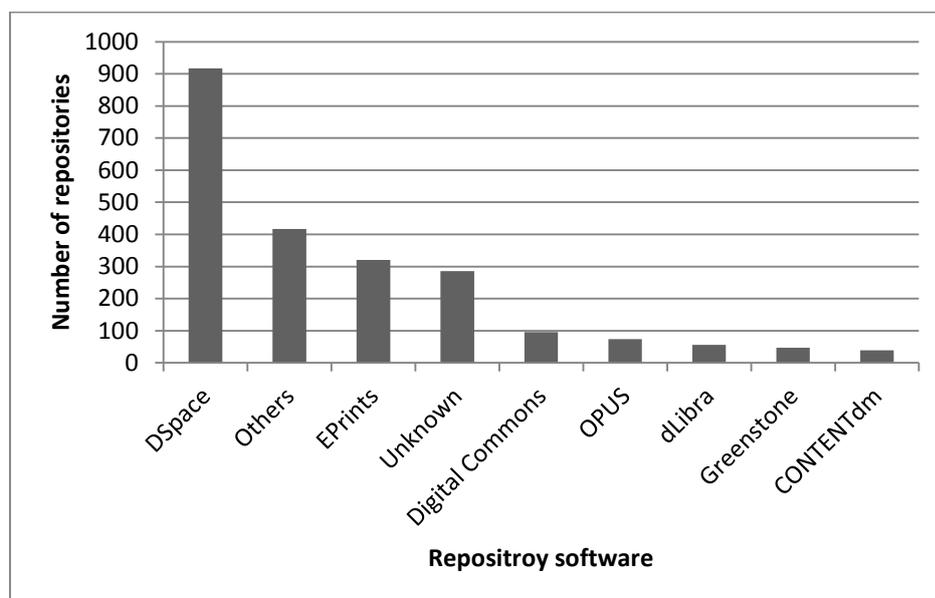

These data (and those in comparable services, such as ROAR) are, however, problematical. The data are gathered by automated harvesting described above, but crucially harvesters cannot distinguish between records in repositories with full content associated with them and those that are metadata only. There is no reliable way automatically to calculate only the number of full-content items housed in repositories, something which can only normally be achieved through case-by-case observation. For example, whilst Europe PubMed Central has over 29 million items listed in *OpenDOAR*, its own website states that it has over 2.6 million full text items and over 28 million abstracts. Very approximately, therefore, 10% of items in the repository are full text. The “Size” count in *OpenDOAR* (or other directories) cannot distinguish between these full-text documents and the abstracts. In a case study of an institutional repository, Brown (2012) discussed the University of Southampton in the UK (a leader of institutional development) and reported that of the 17,317 deposits made to its repository in 2010, 12% were full text. This was an increase on previous years. The balance between full text and metadata records will, of course, vary across different repositories with different policies. Southampton, for example, uses its repository to collect metadata records of all of its publications as a matter of policy, encouraging the additional deposit of full text where possible. Other institutional repositories may *only* accept full text.

The repository size data in *OpenDOAR* should therefore be considered *maximum* figures for full-content items in repositories. Whilst the number of full-content items in any repository may be lower than the *OpenDOAR* size figure, it will not be higher, and therefore the *OpenDOAR* figure represents an upper limit. This helps to put the median repository size figure of 3093 into perspective since it is likely to be considerably higher than the actual number of full-content items. This emphasizes the point that to date repositories tend to be small. It also serves to highlight some significant consequences for assessments of repository development worldwide. It is common for researchers and

OA advocates to make use of *OpenDOAR* data (and those from similar services) uncritically in their analysis of repository size. This may mean that the overall size of the repository infrastructure is at times exaggerated. As observed by Björk et al. (2013), a variety of methods are needed to assess repository size reliably, with *OpenDOAR* data (and those of similar directories) being only one indicator.

### Repository setup

Repository providers typically make use of available open-source OAI-compliant software to run services, with two repository packages dominating: DSpace (917 repositories; 41%) and ePrints (321; 14%) (Figure 12). Between them, DSpace and ePrints account for over half of the repositories worldwide. These two software packages were also predominant in February 2008. However their relative positions have changed since that time. Of the 1072 repositories then, 273 (25%) made use of DSpace, and 209 (19%) ePrints. DSpace has then noticeably gained ‘market’ share.

**Figure 12. Repository software types, December 2012.**

Other repository software and platforms used include Digital Commons, OPUS and dLibra. OPUS use is limited to Germany and dLibra to Poland since these systems were designed in German and Polish respectively. In other non-English-speaking countries, there does not appear to be any language-specific software in widespread use, and so use is made of open-source software such as DSpace or locally-developed solutions which cannot easily be identified. A significant minority of repositories (417 or 19%) use other software, and in the case of 286 (13%) the software could not be ascertained. A large proportion of repositories in these categories are likely to use locally-developed software.

One key feature designed into many repository services is systemic interoperability. The *OpenDOAR* project records where a repository has machine-to-machine protocols enabled (although these data are not yet publicly available in the directory). Unsurprisingly, the most common protocol being used by repositories (1599; 71%) is OAI PMH, although this might be expected to be higher since most of the available open-source software repository packages come with OAI PMH ‘out of the box’ and OAI PMH is the recognized protocol associated with the repository infrastructure. Other protocols being used are RSS (RSS 2: 943 repositories, 42%; RSS 1: 706, 31%; RSS – unspecified: 413, 18%), Atom (619; 27%) and SWORD (448; 19%).

As well as software used, *OpenDOAR* also records repository license conditions. Strikingly, however, the 2253 repositories listed in *OpenDOAR*, as many as 1766 have no evidence of licenses including rights information. Some repositories use licenses to define how content may be reused or harvested, for example, but they are a small minority. The absence of such licenses in the case of most repositories is a major weakness in the repository infrastructure. It means that content from a strictly legal point of view can only be assumed to be Gratis rather than Libre OA and therefore defined reuse rights are very limited.

## Discussion

The data presented here show a clear growth in repositories worldwide between 2005 and 2012. Growth was concentrated initially in Western Europe, North America, and Australasia, closely followed by Japan. More recently, however, growth has widened to include other areas, particularly parts of Asia, Eastern Europe and South America. Africa and Central Asia continue to experience comparatively low levels of repository development. The largest numbers of repositories are still in Europe, North America, and Australasia plus Japan. Repositories are predominantly institutional in their focus and multidisciplinary in their coverage. They contain a wide number of content types, most of which are various forms of research outputs, and most commonly include English-language material. Whilst the size of repositories is difficult to assess accurately, the available data indicate that there are a small number of large repositories and a large number of small repositories making up the repository infrastructure. The most common technical setup for a repository involves the use of open-source OAI-compliant software but, significantly, often does not include any formal licensing of content.

Xia (2012) has demonstrated the utility of Innovation Diffusion Theory (IDT) in explaining some of these global trends and characteristics. In particular, he makes some important observations about geographical variations in adoption of OA which apply to repositories as well as OA journals. He identifies a number of enablers and barriers to adoption which help to explain many of the key trends. In some cases, adoption is explained partly by different levels of existing IT infrastructure. Low levels of infrastructure provision in areas such as Africa and Central Asia, for example, may reasonably be assumed to be significant barriers to repository development. Language is also an important issue. In some cases the predominance of English in OA repositories may be a barrier in non-English-speaking countries, especially in disciplines where there may be a preference for communicating in other

languages or a tendency, as observed by Norris, Oppenheim, & Rowland (2008), to “cite work from their own country preferentially.” In other cases, language can be an enabler: with English increasingly being the “international language of science” (Garfield, 1977; see also Tardy, 2004), it may in many cases encourage communication across borders.

Cultural issues are also important in helping to explain significant variations in adoption between countries. Xia (2012) contrasts Japan and China, for example. In Japan, there was a pre-existing scholarly communication culture which promoted sharing and which therefore created a climate in which rapid adoption of OA was possible. In contrast, in China, Xia argues that researchers, reacting to widely perceived “gray area between reference and plagiarism”, have shown caution about intellectual property loss and therefore a reluctance to adopt OA. In addition, policy developments have played a significant role. In countries such as the UK, Poland and Brazil, a combination of OA policy developments plus funded initiatives from government-sponsored agencies encouraging OA adoption in general and repository development in particular have undoubtedly been important in facilitating growth in repository numbers. However, different policy approaches have led to different outcomes. For example, different development patterns in the UK and France have partly been the result of different policy approaches. Whereas the UK has encouraged and funded the development of distributed institution-based repositories largely through Jisc infrastructure programs, France has encouraged development of a smaller number of more centralized repositories, particularly the CNRS-funded (Centre National de la Recherche Scientifique) HAL (Hyper Articles en Lignes) series of repositories.

In this context, it is important to note that in China and Russia, where there are relatively low numbers of repositories, most of the repositories in existence are institutional. This means that the low number of repositories cannot be explained by a more centralized approach to repository development. In both cases then a combination of factors, including existing IT infrastructure, language, culture, policy and funding, should be brought to bear to explain the current situation.

Innovation Diffusion Theory as proposed by Rogers (2003) shows that in the case of successful innovations early adoption of the innovation is followed by accelerated adoption more widely, creating a classic ‘S-shaped’ adoption curve associated with ‘take off’. It is possible that OA repositories may follow this pattern of adoption globally particularly if repositories become an accepted part of mainstream scholarly practice. However, it is clear that this will partly depend on the precise role that repositories play in future. Advocates of Green OA see repositories as central to a future scholarly communication system, whereas others see repositories as playing a more peripheral role, for example, focusing on managing information such as grey literature and dissertations. The former is more likely to result in global take off, whereas the latter is more likely to result in incremental adoption.

Whilst it is reasonable to hypothesize that use of repositories in a role central to the scholarly communication process in early-adopter countries may accelerate diffusion in other countries, it should however be noted that repository development is likely to continue to be at different stages of the innovation cycle in different countries for the foreseeable future. Whilst there is considerable potential for continuing expansion of the repository infrastructure in many countries, it is probable

that numbers of repositories in certain (early adopter) countries may be nearing saturation point. For example, in the Netherlands and UK, all major research institutions now have repositories and it is therefore likely that growth in the number of repositories will plateau out – data presented here suggest this may have begun to happen. This, of course, applies to the growth in the number of *repositories* rather than growth in their *contents*. As has been shown, for the vast majority of repositories, considerable potential remains to expand content – and IDT can again be usefully deployed to analyze such developments.

Jones et al. (2006) have also used IDT to explain repository development but at a very different level from Xia. They use Diffusion Theory for framing a discussion on institutional repository development, and in particular the design of an advocacy program within an institution aiming to promote repository use amongst academic staff and therefore facilitate growth of repository content. Their analysis provides useful information for practitioners at institutional level whilst at the same time demonstrating the explanatory efficacy of IDT. They draw specifically on the explanation provided by Rogers (2003) of variables determining the rate of adoption of innovations. Rogers identifies five key attributes of innovations which significantly influence rates of adoption, described by Jones et al. as:

- “the *relative advantage* of adopting the new technology;
- the *compatibility* of existing work practices and ethics;
- the *complexity* involved in actually using the innovation;
- the *trialability*, or the degree to which it can be experimented with;
- the *observability* and visibility of the results.”

(Jones et al., 2006, 114)

They go on to explain how IRs containing research outputs correspond to these attributes from the perspective of researchers in an institution. Specifically, they argue that an IR potentially delivers *relative advantage* to researchers by improving the economics of scholarly communication and increasing the visibility of their work. Use of the repository is *compatible* with existing academic values and requirements. It is relatively *un-complex* to use and can be *trialed* by academic staff. Finally, they argue, the repository’s value can be *observed* through increased citation levels associated with OA and other visible impacts. Although these attributes ostensibly create conditions for rapid innovation uptake, major barriers remain, particularly around slow cultural acceptance of repositories and low levels of incentives encouraging individual adoption. Jones et al. suggest a number of practical approaches to addressing these barriers largely associated with awareness-raising and advocacy.

Jones et al.’s analysis relates primarily to the response of *individuals* to the innovation attributes proposed by Rogers (2003) and provides some useful commentary at that level. However, it is worth observing that the attributes may also reasonably be extended to apply to *organizations and communities* making innovation adoption decisions around setting up repositories in the first place as well as to individuals considering contributing content. In the case of repositories, relevant organizations and communities are academic institutions and disciplinary communities. With

reference to Rogers' attributes of innovations, there is certainly an argument that OA repositories containing research outputs can deliver *relative advantage* to organizations by making the outputs of their staff more visible and therefore increasing academic and societal impact. Such an advantage can also be argued to be *compatible* with an academic institution's mission or that of a subject community. Furthermore, repositories are relatively *simple* to set up from an organizational point of view (although the embedding of business processes associated with self-archiving may be more complex). The use of repositories is also clearly *trialable* for organizations in a way that minimizes risk before widespread use is pursued. Finally, the results of repository use can be easily *observed* and monitored by organizations. These innovation attributes then seem to indicate significant potential for organizations in adopting repositories and provide a helpful framework for exploring many of the trends evident in the data reported in this study.

This application of IDT's innovation attributes to apply to organizations complements other aspects of Diffusion Theory as proposed by Rogers (2003) which highlight the importance of organizations. Since organizational adoption of repositories is in most cases the primary innovation decision, with individual user adoption being contingent on that decision, "organizational innovativeness" is crucial. This is influenced by a number of variables identified by Rogers. The first of these is the characteristics of leaders in the organization and their attitude towards change. This has proved to be important in repository development with institutional and subject community leaders often being responsible for championing repository implementation at different stages. Certainly, the 'buy in' of senior managers in an institution and thought leaders in a community has been recognized to be an important factor in repository development (Jones et al., 2006). Much of the future of repository development, it may reasonably be assumed, is likely to be significantly determined by the role taken by senior leaders, especially as repository use widens and starts to come within the purview of a wider range of leaders in institutions not previously involved in OA development or advocacy.

Also important in determining organizational innovativeness are attributes of the organization itself as defined by Rogers (2003), including:

- Centralization: "the degree to which power and control in the system are concentrated in the hands of relatively few individuals"
- Complexity: "the degree to which an organization's members possess a relatively high level of knowledge and expertise"
- Formalization: "the degree to which an organization emphasizes following rules and procedures"
- Interconnectedness: "the degree to which the units in a social system are linked by interpersonal networks"
- Organizational slack: "the degree to which uncommitted resources are available"
- Size: with larger organizations often having greater capacity for innovation.

(Rogers, 2003, 379-383)

Academic institutions and subject communities tend to have characteristics of low centralization, high complexity, and low formalization, with variable interconnectedness, variable organizational slack and variable size. These characteristics are particularly important when considering Rogers'

distinction between different “subprocesses of the innovation”: the “initiation” phase and the “implementation” phase. “Low centralization, high complexity, and low formalization facilitate initiation in the innovation process, but these structural characteristics make it difficult for an organization to implement an innovation.” (Rogers, 2003, 380). This distinction between initiation on the one hand, and implementation on the other is highly relevant in considering organizational adoption of OA repositories to date. In many higher education institutions and subject communities there may be few barriers to the *initiation* of innovation and as a result repositories can be set up quickly. However, achieving widespread *implementation* of the innovation in the organization is demonstrably more difficult, and the difficulty arises because of the *same* characteristics of the organization which made initiation relatively easy. The decentralized nature of decision-making and processes, the high complexity of the organization and its governance, and the low formalization of structures and cultures, mean that the widespread implementation of the innovation, particularly in large organizations, can be delayed. There is then a complex relationship in terms of innovation adoption between the organization as a whole and individual members within it, with initial adoption of the innovation by the organization not necessarily resulting in short-term widespread acceptance by its members. In many early-adopter organizations, it may be observed, this is the stage their repositories have now reached, hence the concerns expressed in the practitioner literature on this topic.

Of course, users within any organization are not homogenous. There may be significant differences between users in terms of adoption of repositories, particularly associated with disciplinary differences (Björk et al., 2013; Kling & McKim, 2000). These have undoubtedly affected the take-up of disciplinary repositories, with some particular subject communities making extensive use of them (for example the high-energy physics community using arXiv). However, disciplinary differences also impact on the use of institutional repositories across a single organization (Spezi, Fry, Creaser, Proberts, & White, 2013; Xia, 2008). Disciplinary differences therefore contribute to the complex set of factors (technological, cultural, and managerial) which affect the interrelationships between individuals, institutions and scholarly communities which have determined the shape of repository adoption to date and are likely to impact on the future development trajectories.

However, there is one additional factor to consider in this context which has impacted on development to date and could potentially have a determining role in future adoption: the *type* of innovation decision. Rogers observes that decisions can either be optional (where individuals have choice in whether they adopt the innovation) or authority-based (where relatively small numbers of people in an organization or community determine adoption). In the case of many repositories, innovation initiation may have been carried out by a relatively small number of people but wider implementation often remains optional. Such optionality has often led to low levels of repository usage by faculty. However, IDT does recognize that on occasions “a higher level social organization such as a government, community, or a commercial company can exert its influence on the behavior of individual members of the system” and “mandate adoption” of the innovation (Rogers, 2003, 239). This often occurs where adoption can create system-wide benefits but the incentives for specific individuals to adopt voluntarily the innovation may be low – a factor which is important for OA in general and repository implementation in particular.

Mandates of various kinds have been introduced in order to encourage the adoption of OA, including use of repositories (Kennan, 2011; Xia et al., 2012). In most cases, mandates focus on author deposit of content, although imply, and may sometimes specify, organizational adoption of repositories upon which user self-archiving is contingent. Some mandates have been introduced by institutions, encouraging OA adoption amongst their members (usually involving deposit in their own IR). However, the nature of the institutions as described above, has meant that these mandates are usually not easily enforceable, particularly in a context where incentives for implementation are often relatively low and sanctions for non-compliance minimal (Sale, 2006). There are, however, notable exceptions to this, where strongly-worded policies combined with relevant incentives and sanctions can increase deposit rates significantly (Lariviere et al., 2012). Nevertheless, as well as institutions, increasingly governments and research funders (government-sponsored and independent) have begun to introduce OA mandates. Because their mandates generally have a much wider coverage than institution-specific policies and also, because they often introduce meaningful incentives and sanctions, they are often more likely to create significant levels of change in author behavior, particularly when combined with institution-level compliance programs.

Mandates have been introduced by a number of funders since 2003. In that year, a number of research funders in Germany issued the Berlin Declaration declaring their support for open access (Max Planck Society, 2003). A year later in the USA, the National Institutes of Health (NIH) in the USA introduced a mandate for all of its grant holders to make their work OA (O’Keeffe, Willinsky, & Maggio, 2011). This was followed in 2005 by the Wellcome Trust in the UK introducing a more strongly-worded mandate (Walport & Kiley, 2006). A large number of other governments and funders have introduced such policies since. In the last two years, there has been and further activity to strengthen the wording of such mandates, ‘requiring’ rather than ‘encouraging’ deposit in a repository, for example. Also, the introduction of meaningful incentives and sanctions to encourage compliance have been apparent, including, for example, withholding parts of grants until compliance can be demonstrated. At the same time, levels of compliance are also beginning to be monitored by funders. In the UK, for example, the Wellcome Trust now actively monitors compliance with its mandate and has introduced measures involving sanctions, such as withholding funding in various ways in the event of non-compliance (Wellcome Trust, 2012). In January 2013, Kiley (2013) reported compliance levels for Wellcome-funded research outputs to be around 60% in March 2012 compared with less than 20% in March 2007. Also, the government-sponsored Research Councils have issued a joint policy which aims to ensure that all of its grant holders make their work open access, preferably via the Gold route but also allowing for Green OA (RCUK, 2013). More recently, the Higher Education Funding Council for England has proposed that the research assessment process that it manages (the Research Excellence Framework) will in future involve the expectation that all work submitted for assessment should be made available in an institutional repository (HEFCE, 2013). If the latter policy was to be implemented, it would significantly increase the likelihood of widespread adoption of repositories by UK researchers. Similar developments are underway, for example, in the USA, with the Federal Fair Access to Science and Technology Research (FASTR) bill announced in February 2013 and a new OA policy memorandum issued by the Office of Science and Technology Policy (OSTP) the same month (Kaiser, 2013).

Evidence suggests that mandates may be crucial in determining the future development trajectory of repositories, particularly in terms of widespread *implementation* and use. If they are to be effective, mandates clearly need to be worded in a robust way and complemented by meaningful incentives and sanctions as well as accompanied by compliance monitoring. The importance of the policy developments now taking place particularly in the repository early-adopter countries, are yet to be seen both in terms of OA in general and repositories in particular. However, there is a strong possibility that they will have a significant impact on the use of the repository infrastructure in those countries and that that impact will in turn accelerate diffusion in other countries, both in terms of the growth of repository numbers and repository content. It is likely, however, that different countries will continue to proceed at different speeds depending on the complex set of technical, cultural, managerial and economic factors. Such developments need to continue to be tracked and monitored.

At the same time, cultures of communication are changing. Greater experimentation in scholarly communication is happening in a large number of ways, much of it increasingly open access. Whilst this varies across disciplines, and disciplinary differences will certainly continue to be important, it is likely to impact on the use of repositories by various subject communities. This is particularly the case as other open developments, including data sharing and exchange of learning objects (which are themselves often associated with repositories), also become more embedded in academic practice.

## Conclusion

The data from the *OpenDOAR* service presented here provide an important perspective on the development of the global repository infrastructure from 2005 to 2012. They show that early adoption, concentrated in Western Europe, North America and Australasia, has been followed by development in other areas including East Asia, South America and Eastern Europe. However, areas such as Africa and Central Asia, and countries such as China and Russia, have experienced relatively low levels of growth throughout the period. Globally, repositories are predominantly institutional, multidisciplinary and English-language-based. They are typically set up using open-source OAI-compliant repository software but remain immature in terms of explicit licensing arrangements. Crucially, they are for the most part relatively small in terms of content. Further work is needed to continue to monitor global development trends of repositories and to assess the importance of the various factors which influence those developments. In particular, more work is required to assess reliably content growth in repositories. Work is also required to strengthen repository services themselves, particularly around the creation of explicit license agreements to enable the reuse of resources.

The global trends described here can be explained by a number of factors informed particularly by Innovation Diffusion Theory. Amongst these, existing IT infrastructure and language play an important role. However, a complex set of cultural factors along with policy and funding initiatives are also crucial. They suggest that different countries may continue to proceed at different speeds in the innovation process with the ultimate trajectory of the growth curve dependent on the final role the repositories have in scholarly practice.

The setting up of repositories by particular institutions or subject communities is partly determined by the attributes of the innovation itself. It may be seen that repositories create ostensible relative advantage for the organization adopting them and its members: they are compatible with existing working practices and values, they are relatively un-complex to use, they are trialable, and their results are visible – factors which create potential for successful innovation. As well as the innovation attributes, the attributes of the organization are also crucial. However, it may be observed that the attributes of academic organizations, which may make *initiation* of repository developments relatively easy (including low centralization, high complexity and low formalization), may actually contribute to making widespread *implementation* of repositories problematical. Evidence suggests that many repositories, particularly institutional repositories, are not being widely used by researchers with overall deposit levels remaining relatively low. Strong leadership in an organization combined with awareness-raising and advocacy programs promoting the use of repositories (themselves informed by the key innovation and organizational attributes relating to repositories) will undoubtedly go some way to addressing these issues. Further work is needed to analyze the effectiveness of such initiatives.

However, an equally important consideration is the level of voluntariness in adoption of repositories. Evidence suggests that mandates may accelerate adoption and therefore may be crucial in determining future adoption patterns. Whilst institutional mandates have some role to play, funder or governmental mandates are more likely to have a greater impact. Their impact does, however, largely depend on the extent to which they are worded robustly, complemented by meaningful incentives and sanctions, and accompanied by compliance monitoring. Recent developments in these areas in a number of repository early-adopter countries are likely to have significant impact within their own countries and this is likely to extend more widely. Their impact needs to be monitored and analyzed.

The complex relationships between individual researchers, their organizations and subject communities, and their funders and governments, and the contributions all these actors make to repository development, need to be further explored in order to explain ongoing developments. Open-access approaches in general, and OA repositories in particular, have the potential to transform scholarly practice. The period since 2005 has seen considerable change in this area, with a repository infrastructure being established which is capable of playing an important role in scholarly communication. However, it is the next decade which is likely to reveal the extent to which these changes make a widespread and enduring impact on the scholarly community.
