Abstract The synthesis of four 3,4-di(alkylsulfanyl)benzyl alcohol derivatives is described, in five steps from methyl 3,4-dihydroxybenzoate via a Newman-Kwart rearrangement. Incubation of these derivatives in formic acid affords 2,3,7,8,12,13-hexakis(alkylsulfanyl)-10,15-dihydro-5\textsuperscript{H}-tribenzo[a,d,g]cyclononene products, which are hexa-sulfanyl analogues of the well-known supramolecular cavitand host, cyclotriveratrylene (CTV). The yield of this cyclization depends strongly on the alkylsulfanyl substituents present, in the order SMe > SEt ≈ SiPr >> SBn. A crystal structure determination of one of the cyclotrimers shows a mode of self-association that is commonly exhibited by CTV itself.

Cyclotriveratrylene (2,3,7,8,12,13-hexamethoxy-10,15-dihydro-5\textsuperscript{H}-tribenzo[a,d,g]cyclononene, CTV; Scheme 1) is a rigid bowl-shaped molecule that is an important synthon in supramolecular chemistry.\textsuperscript{1-3} CTV itself can complex fullerenes or other globular molecular guests within its hydrophobic cavity. Moreover, other functionalities can be appended onto the CTV scaffold by derivatization of its methoxy groups, allowing organic\textsuperscript{2-5} and metal-organic\textsuperscript{2,6,7} cage compounds, frameworks and other supramolecular assemblies\textsuperscript{8} based on the CTV moiety to be constructed. Recently, we\textsuperscript{9,10} and others\textsuperscript{11,12} have extended the chemistry of CTV by preparing thiolated analogues 1 and 2 (Scheme 1). Oxidative dimerization of 1 under high-dilution conditions affords the cryptophane-0.0.0 capsule 3, one of the smallest organic capsules yet reported, which binds methane in solution.\textsuperscript{9} A larger capsule molecule was similarly achieved by oxidatively coupling 1 with a trimercapto-cycloextrin.\textsuperscript{13} As a continuation of this work, we were keen to obtain hexa-sulfanyl analogues of CTV, bearing purely thyl or sulfanyl substituents at the upper rim. We report here the synthesis of several new 3,4-disulfanylbenzyl alcohol derivatives, and their cyclotrimerization into 2,3,7,8,12,13-hexakis-(alkylsulfanyl)-10,15-dihydro-5\textsuperscript{H}-tribenzo[a,d,g]cyclononene cavitands 4a-4d.

\textbf{Scheme 1.} Cyclotriveratrylene (CTV), and its sulfur-containing analogues referred to in this work.
We first attempted to access hexa-sulfanyl analogues of CTV by the same method we successfully used for 1 and 2. That is, by a Newman-Kwart rearrangement\(^1\) from the tris-catechol cyclo-tricatechylene (2,3,7,8,12,13-hexahydroxy-10,15-dihydro-5H-trienz[a,d,g]cyclononene, CTC; Scheme 2), which is readily prepared by exhaustive demethylation of CTV with BBr\(_3\). The hexakis-N,N-dimethylthiocarbamoyl Newman-Kwart precursor 5 was obtained in good yield by treatment of CTC with Me\(_2\)NC(S)Cl in the presence of excess Cs\(_2\)CO\(_3\). However, heating 5 in diphenyl ether led to its decomposition above 180 °C, with no rearrangement product being observed. This is an insufficiently high temperature for a Newman-Kwart rearrangement to proceed in this system. For comparison, the corresponding rearrangement reactions in the syntheses of 1 and 2 from preformed CTV-type precursors proceeded at 255 °C and 305 °C, respectively.\(^9\) Palladium catalysis can reduce the temperature required for the Newman-Kwart rearrangement.\(^15\) That was not attempted in this study, however, because that protocol did not give useful yields in the synthesis of 1 and 2.\(^9\)

![Scheme 2. Attempted Newman-Kwart rearrangement from pre-formed cyclotricatechylene. Reagents and conditions: (i) Me\(_2\)NC(S)Cl, Cs\(_2\)CO\(_3\), DMF. (ii) Ph\(_2\)O, 180 °C.](image)

CTV is prepared by the acid-catalysed trimerization of 3,4-dimethoxybenzyl alcohol.\(^1\) We therefore pursued (previously unknown) 3,4-disulfanylbenzyl alcohol derivatives, that could be similarly cyclotrimerized to form 4a-4d. Since 3,4-dihydroxybenzyl derivatives are readily available, a Newman-Kwart route to these products was also employed (Scheme 3).

Attempted Newman-Kwart rearrangements employing 3,4-di(N,N-dimethylthiocarbamoyloxy)benzaldehyde (6) or 3,4-di(N,N-dimethylthiocarbamoyl-oxy)benzoate (8) were also unsuccessful, with decomposition being observed near 160 °C before a sufficiently high temperature could be reached (see above).\(^15\) However, methyl 3,4-di(N,N-dimethylthiocarbamoyloxy)benzyl alcohol (7) were also unsuccessful, with decomposition being observed near 160 °C before a sufficiently high temperature could be reached (see above).\(^15\) Heating 9 with aqueous NaOH leads to simultaneous removal of the thione protecting group and hydrolysis of the ester function, affording 3,4-dimercaptobenzonic acid (10) almost quantitatively. Reduction of 10 with LiAlH\(_4\) afforded 3,4-dimercaptobenzyl alcohol (11) in good yield. Alternatively, alkylation of 10 with the appropriate alkyl bromide or alkyl iodide in the presence of NaOH gave the 3,4-di(alkylsulfanyl)benzonic acid derivatives 13a-13d, which were then reduced to the equivalent benzyl alcohols 14a-14d with LiAlH\(_4\). Although 13a-13d all contained 15-20% of mono-alkylated impurities, this did not interfere with their use in the reduction step and 14a-14d were subsequently purified by chromatography. Attempts to shorten this reaction sequence, by reducing 9 to the corresponding alcohol with NaBH\(_4\) or LiAlH\(_4\), led to preferential removal of the thione moiety with little reduction of the ester group being observed.

Cyclotrimerization of 14a-14d to the desired 2,3,7,8,12,13-hexakis(alkylsulfanyl)-10,15-dihydro-5H-trienz[a,d,g]cyclononenes 4a-4d was achieved by heating in formic acid (Scheme 3).\(^17\) The yields of the reaction depended significantly on the alkylsulfanyl substituents present, in the order 4a (R = Me) > 4b (R = Et) ≈ 4c (R = iPr) >> 4d (R = Bn). The trace yield of 4d is consistent with the mechanism of the reaction, which couples the benzyl alcohol monomers by a sequence of electrophilic aromatic substitution steps. These will be disfavored by the more inductively withdrawing sulfanyl substituents on the benzyl alcohol precursors. Formation of the macroyclic products was confirmed by the \(^1\)H NMR signature of their chemically equivalent CH\(_2\) groups, which are diastereotopic in the rigid bowl-shaped conformation adopted by the molecules. These groups are observed as two geminally coupled doublets near 3.7 and 4.7 ppm, assignable to the \(H_{exo}\) and \(H_{endo}\) environments respectively. Attempted cyclotrimerization of dithiol 11 to the hexa-mercapto derivative 12, in formic acid\(^17\) or in MeCN with a Sc(CF\(_3\)SO\(_2\))\(_3\) catalyst,\(^18\) did not go to completion and gave a mixture of bis-di[alkylsulfanyl]phenyl)methane-containing species by mass spectrometry.
Scheme 3. Synthesis of 3,4-di(alkylsulfanyl)benzyl alcohol derivatives, and their conversion into the desired cyclic trimer cavitand compounds 4a-4d. Reagents and conditions: (i) Me₂NC(S)Cl, DABCO, DMF. (ii) Ph₂O, 160-280 °C. (iii) NaBH₄, THF. (iv) Ph₂O, 240 °C, 1 h. (v) NaOH (aq), 70 °C, 6 h then 1M HCl. (vi) LiAlH₄, THF, 0 °C→RT, 18 h. (vii) HCO₂H, 70 °C or Sc(CF₃SO₂)₃, MeCN, 60 °C. (viii) NaOH, MeOH then RBr or RI, acetone, reflux, 4 h. (ix) HCO₂H, 70 °C, 48 h.

The identity of 4c was confirmed by a crystal structure determination, which showed it to adopt the expected bowl-shaped conformation (Figure 1). While four of the six SiPr substituents are approximately coplanar with their bound phenylene group, the other two project into the molecular bowl. Molecular models imply that this should reflect steric congestion between iso-propyl groups around the rim of the molecule. Interconversion between the SiPr group conformations in 4c is slow in solution by ¹H NMR spectroscopy, since the tPr methyl groups are observed as at least three overlapping doublets whose integrals sum to the expected 36H (see the Supplementary Information). There is no comparable splitting of the substituent resonances in the ¹H NMR spectra of the other cyclotrimers with smaller, less hindered sulfanyl groups.

Molecules of 4c associate into centrosymmetric dimers in the crystal, by inclusion of one “out-of-plane” iso-propyl group from each molecule into the hydrophobic cavity of its neighbor (Figure 2). This “handshake” dimerization is common in crystalline CTV derivatives, which associate by intermolecular inclusion of their methyl groups (Figure 2). The observation of the same motif in 4c, despite the increased bulk of the included iso-propyl groups, indicates that the host:guest chemistry of 4a-4d should be comparable to CTV derivatives.
Figure 1. View of the molecule of 4c in its crystal structure, showing the atom numbering scheme employed. Displacement ellipsoids are at the 50% probability level, and H atoms have been omitted.

Figure 2. Top: the “handshake” dimerization of 4c in the crystal. The C and H atoms in the two molecules have pale and dark colouration. Bottom: the same view as a space-filling plot.
In conclusion, we have reported here a general synthesis of 3,4-di(alkylsulfanyl)benzyl alcohols, employing a Newman-Kwart rearrangement procedure. These can be converted into cyclic, bowl-shaped molecules that are hexa-sulfanyl analogues of the well-known supramolecular cavitation CTV. Preliminary attempts to obtain the hexamer-capto derivative 12 by a Pummerer rearrangement from 4a, and by deprotection of 4b with Na/HMPA, have been unsuccessful. While the benzyl groups in 4d should be easier to remove, the low yield of that compound precludes its use as a precursor to 12. None-the-less, as well as being of interest in their own right, 4a-4d could also be used as components in metal/organic supramolecular assemblies, through chelation of transition ions by their 1,2-di(alkylsulfanyl) moieties. Our synthetic route to 4a-4d could also be adapted to yield larger hexa-sulfanyl assemblies or cage compounds based on thioether linkers. Current work is aimed at investigating these possibilities.
