24

25 **ABSTRACT**

26 **Objective:** Many patients are satisfied with their ocular prosthesis, but some describe problems
27 with social interactions, body image and self-esteem. Although both clinical practice and
28 research suggest that the severity of a disfiguring condition does not predict distress, there has
29 been little research with patients living with an ocular prosthesis. The objective was to explore
30 the psychological impact of living with an artificial eye or cosmetic shell and determine the
31 relationship between psychological well-being and clinical and psychosocial factors.

32 **Methods:** A cross-sectional study between March and September 2008 at the ocular prosthesis
33 clinic of Moorfields Eye Hospital, UK. The primary outcome measures were mood as measured
34 by the Hospital Anxiety and Depression Scale (HADS) and appearance-related social anxiety and
35 social avoidance, as measured by the Derriford Appearance Scale (DAS24).

36 **Results:** Mean scores on the HADS and DAS24 were within normal range, but a considerable
37 proportion of participants were experiencing significant levels of distress. Psychosocial
38 adjustment was unrelated to most clinical and demographic variables, but was associated with a
39 series of cognitive processes.

40 **Conclusions:** Psychological variables, rather than clinical or demographic factors, are associated
41 with how a patient adjusts to wearing an ocular prosthesis. Such factors might be amenable to
42 change through psychosocial intervention.

43

44 **Key words:** disfigurement, ophthalmology, anxiety, depression, prosthesis

45

46

47

48

49 **Introduction**

50 Ocular prostheses are used in the management of a wide variety of acquired and congenital
51 disease, often after evisceration, enucleation or orbital exenteration. Despite the disfiguring
52 nature and difficult management of such conditions, the psychological consequences of living
53 with an ocular prosthesis are poorly understood.

54

55 The eyes are important for inter-personal communication.(1) All artificial eyes have somewhat
56 limited motility and orbito-facial prostheses have none, thus affecting eye contact during
57 personal interactions. Nonetheless, patients frequently express high levels of satisfaction with
58 the shape, colour, mobility, fixation and comfort of an ocular prosthesis.(2) Satisfaction has
59 been found to be greater for those who feel that their artificial eye is imperceptible to others
60 and this is unrelated to type of surgery or orbital implant.(3) Although research suggests that
61 adjusting to life with an ocular prosthesis can happen within the first 6 months(4) for about 40%
62 of patients this can take 2 years or more.(5)

63

64 Early research has emphasized the importance of psychological outcomes after
65 enucleation.(5;6) Quality of life (QoL) has been found to be severely affected(7;8) and although
66 research has shown that patients with an ocular prosthesis exhibit levels of anxiety and
67 depression that are within the normal range,(8-10) the prevalence of clinical anxiety or
68 depression is over 28%. Higher levels of anxiety and depression have been linked to older age,
69 being married, having children and the belief that the prosthesis highly influences social and
70 interpersonal relationships.(8) In contrast Wang and colleagues(10) found that before orbital
71 insertion 49% of participants exhibited clinical levels of anxiety and this dropped to 10% after
72 treatment.

73

74 Whilst previous reports have considered the extent of psychological adjustment for individuals
75 living with an ocular prosthesis this study represents not only a detailed investigation of two
76 important psychological outcomes, mood and social avoidance. It also aims to explore the
77 relationship between these variables and clinical, demographic and intervening psychological
78 processes. Identification of these process variables is of clinical importance as these factors
79 might be amenable to intervention, thereby providing avenues to improve the psychosocial
80 well-being of such patients.

81

82 The primary aim of this study was to determine the psychosocial well-being of patients wearing
83 an ocular prosthesis and, secondarily, to determine the relationship between these measures
84 and clinical, demographic and cognitive processes.

85

86

87 **Materials and methods**

88 SETTING

89 A cross-sectional study was undertaken with participants recruited in an outpatient clinic at
90 Moorfields Eye Hospital, London. Participants either completed the questionnaire at the
91 hospital or at home, the questionnaires containing a number of demographic and psychosocial
92 questions.

93

94 ETHICS

95 The study was performed according to the Declarations of Helsinki.

96

97 PATIENTS AND STUDY POPULATION

98 Patients attending the ocular prosthetics clinic at Moorfields Eye Hospital, London were
99 approached to take part in the study; they were considered eligible for recruitment if aged over
100 17 years and living with an ocular or orbital prosthesis. We excluded those likely to be
101 distressed by taking part in the study or those judged to be too physically frail (as judged by the
102 ocularist). Ninety-eight participants were recruited into the study and completed questionnaires
103 were received from 39 (39.79%) participants.

104

105 MATERIALS

106 How people adjust to living with a visible difference is multifaceted and current models that aim
107 to understand this process fail to capture these complexities. A number of psychosocial
108 variables that are potentially amenable to change have been identified and developed into a
109 framework by the Appearance Research Collaboration (ARC). This framework aims to capture
110 the range of experiences of those affected by a visible difference, along with indentifying a
111 number of factors that might predict adjustment (Figure 1). Using this framework data were
112 collected on the following variables:

113

114 *Predisposing factors*

115 Gender, age, ethnicity, current living arrangements (i.e. living alone, living with
116 friends/family, living with partner), age of acquisition, duration of prosthesis wear (from first
117 fitting), aetiology and type of prosthesis.

118

119 *Intervening cognitive processes*

120 Dispositional style

121 Levels of optimism were measured using the four-item version of the Life Orientation Test-
122 Revised(11). Questions include 'I am always optimistic about my future'. Responses are on a
123 five-point Likert scale, ranging from 1 (strongly agree) to 5 (strong disagree). Total score ranges
124 from 4-20, with higher scores indicating a more optimistic outlook.

125

126 *Socio-cognitive factors*

127 Satisfaction with Social support

128 Quality of social support was assessed using the four-item version of the Short Form Social
129 Support Questionnaire(12) which asks how satisfied a person is with different types of support
130 including practically and socially.. Quality ratings ranged from 1 (very satisfied) to 6 (very
131 dissatisfied), with total scores ranging from 4-24. Higher scores represent a greater satisfaction
132 with one's social network.

133 Feelings of social acceptance

134 Two items, with a seven-point Likert scale ranging from 1 (not at all) to 7 (completely), were
135 used to assess the extent to which the respondent felt accepted by their social group and by
136 society in general. Total scores range from 2 to 14, with higher scores indicating greater
137 subjective feelings of acceptance.

138 Fears of Negative Evaluation (FNE) scale(13)

139 This 12-item scale examines the extent to which an individual is concerned by other people's
140 opinion of them. Questions include 'I am afraid that other people will find fault with me' and 'If I
141 know someone is judging me, it has little effect on me'. Scores range from 12 to 60, with high
142 scores indicating a greater fear of negative evaluation.

143 Netherlands Comparison Orientation Measure (NCO)(14)

144 The NCO comprises 11 items, rating how often the respondent compares themselves with others.
145 Questions include 'I am not the type of person who compares often with others' and 'I always
146 like to know what others in a similar situation would do'. Responses range from 1 (strong
147 disagree) to 5 (strongly agree), and higher scores indicating a greater level of social comparison.

148

149

150 *Appearance-related cognitions*

151 Disguisability

152 Participants were asked to rate how difficult they felt it was to disguise this area of concern, on
153 a Likert scale ranging from 1 (extremely easy) to 7 (impossible).

154 The Valence and Saliency of Appearance Scales (CARVAL, CARSAL)(15)

155 The CARVAL is a 6-item questionnaire that measures how a participant evaluates their own
156 appearance (valence), with higher scores indicating a more negative evaluation. Questions
157 include 'My body and face look pretty much the way I would like' and 'I don't like the way I
158 look'. CARSAL measures the extent to which appearance is part of a person's working self-
159 concept or how important it is to them (saliency), with higher scores indicating that appearance
160 forms a greater part of their self-concept or is more important to them. Questions include 'I am
161 usually conscious of my appearance' and 'For me, my appearance is an important part of who I
162 am'.

163 Responses range from 1 (strongly agree) to 6 (strongly disagree) for each item (total ranging
164 from 6 to 36).

165 Physical Appearance Discrepancy Questionnaire (PADQ)(16)

166 The PADQ evaluates the discrepancy between how a person thinks they look and how they (or
167 others) would ideally like them to look. Questions include 'How different from your ideal

168 appearance do you think you look?’ and ‘How different are you from the way your friends think
169 you should look?’. The scale consists of 8 items, each, with responses ranging from 1 (not at all
170 different) to 7 (extremely different), and a higher score indicating greater discrepancy.

171

172 *Primary outcome measures*

173 The Derriford Appearance Scale short form (DAS24)(17;18)

174 The DAS24, a 24-item version of the DAS59,(19) is a measure of social anxiety and social
175 avoidance in relation to appearance. Questions include ‘How distressed do you get when you
176 see yourself in the mirror/window?’ and ‘How distressed do you get when going to social
177 events?’. The total score ranges from 11 to 96, with lower scores representing low levels of
178 social anxiety and social avoidance.

179 The Hospital Anxiety & Depression Scale (HADS)(20)

180 The HADS is a validated, reliable 14-item self-screening questionnaire for depression and
181 anxiety, for use in patients with physical health problems. Questions include ‘I still enjoy the
182 things I used to enjoy’ and ‘I can laugh and see the funny side of things’. Scores range from 0 to
183 21, with higher scores indicating greater levels of depression or anxiety. For both subscales, a
184 score of 0–7 is regarded as being in the ‘normal’ range, 8–10 is suggestive of moderate levels of
185 anxiety or depression, and greater than 10 indicates a high likelihood that such a patient would
186 receive a diagnosis of clinical anxiety or clinical depression.

187

188 STATISTICAL ANALYSIS

189 Data was analyzed using SPSS v.16 (SPSS Inc, Chicago, Illinois). Scores for different groups
190 were compared using one-way ANOVA, with an α -risk of 0.05. The relationship between

191 pairs of variables was investigated using the Pearson product-moment correlation
192 coefficient.

193

194

195 **Results**

196 Completed questionnaire were received by 39 patients (18 female, 46%) and of these 37 (95%)
197 indicated that the appearance of their eyes caused them some concern. Demographic and
198 other group characteristics are summarised in Table I.

199

200 All psychometric measures show good internal consistency, with Cronbach's alphas greater than
201 0.7. Table II displays descriptive statistics for all variables. Although mean scores for anxiety and
202 depression are within the accepted normal range, the results suggest that 18% (n=7) of the
203 patients were experiencing clinical depression and 18% (n=7) clinical anxiety; this included 3
204 participants who were experiencing both clinical anxiety and depression. Although scores for
205 appearance-related social anxiety and social avoidance (mean 37.5, standard deviation 14.7,
206 standard error of mean 1.96) are within the normal range, 21% (n=8) of patients reported
207 considerable levels of social anxiety and avoidance in relation to their appearance.

208

209 Appearance-related social anxiety and avoidance

210 The DAS24 correlated significantly with social acceptance ($r = -0.46$, $p = 0.01$) and valence ($r =$
211 0.55 , $p = 0.02$), There were no significant associations between the DAS24 and any other
212 demographic, clinical or psychosocial variable.

213

214 Anxiety and depression

215 The pattern of correlations for anxiety and depression differed: anxiety was correlated
216 significantly with disguisability ($r = 0.46, p = 0.01$), self-discrepancy ($r = 0.48, p < 0.01$), valence (r
217 $= 0.45, p = 0.01$) and salience ($r = 0.45, p = 0.01$). Depression significantly correlated with social
218 acceptance ($r = -0.46, p < 0.01$), self-discrepancy ($r = 0.52, p < 0.01$), optimism ($r = -0.50, p <$
219 0.01) and valence ($r = 0.58, p < 0.01$). As compared with those living with someone (friends,
220 family or a partner), those living alone experienced significantly higher levels of depression
221 (living alone 10.4, living with someone 7.00; $F_{(1, 66.06)} = 5.37, p = 0.02$), with a large effect size
222 (Cohen's $d = 0.99$). There were no significant associations between anxiety or depression and
223 any other demographic, clinical or psychosocial variable.

224

225

226 **Discussion**

227 Contrary to the expectations of many healthcare professionals and consistent with research in
228 other areas(21) this study suggests that the psychological well-being of those living with an
229 ocular prosthesis is not related to duration of prosthetic wear, age of acquisition, gender,
230 current age or type of prosthesis. Rather poor psychological well-being was related to having a
231 pessimistic outlook and the beliefs a patient has about their appearance and how accepted they
232 feel by society. This study also highlights the importance of instrumental support, as those
233 participants living with a partner, family or friends had lower levels of depression than those
234 living alone. The identification of these underlying cognitive processes is of importance as
235 clinicians can now identify patients who are experiencing considerable levels of psychological
236 distress and target these potentially modifiable cognitive processes through psychological
237 intervention, thus potentially improving the well-being of this population.

238

239 Levels of anxiety and depression were within the normal to moderate range, some patients had
240 scores indicating a possible clinical diagnosis of anxiety or depression. The proportion of such
241 patients was considerably higher than would be expected in the general population,(22) and
242 greater than that reported by Wang and colleagues(10) in a study post insertion of a secondary
243 hydroxyapatite orbital implant but considerably lower as compared to a group of Korean
244 anophthalmic patients.(8) The degree of appearance-related social anxiety and avoidance is
245 somewhat higher than that of the general population,(17) and patients post orbital
246 insertion.(10) Suggesting that this population experience considerable generalised anxiety and
247 depression and also anxiety specific to social situations and hence use techniques and strategies
248 to hide their appearance and avoid social interaction.

249

250 This investigation has some limitations that need to be acknowledged. The study was
251 exploratory, cross-sectional, and with a modest sample size. Over 40% of the sample failed to
252 return a completed questionnaire, potentially biasing the results of the study. It may be that
253 either appearance was a greater concern for those who chose not to participate or they may
254 have been experiencing greater levels of anxiety or depression. Generalization to other ocular
255 prosthetics patients should be made with caution, as only patients attending for prosthetics
256 fitting were recruited. Thereby excluding long-term prosthetics wearers not being followed up
257 in clinic; such patients might either be very happy with their prosthesis, or perhaps silently
258 bearing a considerable psychological burden. The cross-sectional nature of this investigation
259 precludes an examination of how individuals change over time and adjust to their prosthesis.
260 Furthermore, although a number of specific cognitive processes have been found to significantly
261 correlate with psychological well-being, any causal relationship between these factors and
262 adjustment remains unclear. Future work might benefit from exploring the role of other clinical

263 measures of prosthetic performance, such as visual acuity and field in the remaining eye,
264 comfort of the prosthetic, or discharge from the socket.

265

266 The results of this study are, nevertheless, of clinical importance. The proportion of patients
267 with clinical anxiety or depression highlights a need to identify such patients and implement
268 referral pathways for appropriate management. This identification of patients needing
269 psychological care might be best achieved by using validated measurement tools such as the
270 HADS or DAS24.

271

272 Successful adaptation to an artificial eye appears to be associated with a number of underlying
273 beliefs held by the patient, rather than clinical aspects of their condition. The identification of
274 these factors provides a better understanding of the distress experienced by patients living with
275 an ocular prosthesis and offers a potential therapeutic opportunity through psychological
276 interventions such as cognitive behavioural therapy.

277

278 **Declarations of interest**

279 The authors report no conflicts of interest. The authors alone are responsible for the content
280 and writing of the paper.

281

282 **Acknowledgements**

283 Funding for the study was provided by the Healing Foundation in association with the Welton
284 foundation and the Worshipful Company of Tin Plate Workers. The authors would like to
285 acknowledge the ARC Advisory Committee, in particular, Olivia Giles, Pam Warren & Luke
286 Wiseman for their input into the ARC research programme.
