31

32 Abstract

33 Whilst genotype–environment interaction is increasingly receiving attention by
34 ecologists and evolutionary biologists, such studies need genetically homogeneous
35 replicates—a challenging hurdle in outcrossing plants. This could potentially be
36 overcome by using tissue culture techniques. However, plants regenerated from tissue
37 culture may show aberrant phenotypes and “somaclonal” variation. Here we examined
38 the somaclonal variation due to tissue culturing using the response to cold treatment
39 of the photosynthetic efficiency (chlorophyll fluorescence measurements for F_v/F_m ,
40 F_v'/F_m' and Φ_{PSII} , representing maximum efficiency of photosynthesis for dark- and
41 light-adapted leaves, and the actual electron transport operating efficiency,
42 respectively, which are reliable indicators of photoinhibition and damage to the
43 photosynthetic electron transport system). We compared this to variation among half-
44 sibling seedlings from three different families of *Arabidopsis lyrata* ssp. *petraea*.
45 Somaclonal variation was limited and we could successfully detect within-family
46 variation in change in chlorophyll fluorescence due to cold shock with the help of
47 tissue-culture derived replicates. Icelandic and Norwegian families exhibited higher
48 chlorophyll fluorescence, suggesting higher performance after cold shock, than a
49 Swedish family. Although the main effect of tissue culture on F_v/F_m , F_v'/F_m' and Φ_{PSII}
50 was small, there were significant interactions between tissue culture and family,
51 suggesting that the effect of tissue culture is genotype-specific. Tissue-cultured
52 plantlets were less affected by cold treatment than seedlings, but to a different extent
53 in each family. These interactive effects, however, were comparable to, or much
54 smaller than the single effect of family. These results suggest that tissue culture is a
55 useful method for obtaining genetically homogenous replicates for studying

56 genotype–environment interaction related to adaptively-relevant phenotypes, such as
57 cold response, in non-model outcrossing plants.

58 Introduction

59 Genotype–environment interaction effects on a phenotype, or variation in reaction
60 norms, may modulate natural selection (Wright 1931; Sultan 1987). The genetic basis
61 of genotype–environment interaction is increasingly receiving attention (El-Soda *et al.*
62 2014; Yap *et al.* 2011); however, such advances have been concentrated in inbreeding
63 organisms such as *Arabidopsis thaliana* (e.g. Bloomer *et al.* 2014; El-Soda *et al.*
64 2014; Sasaki *et al.* 2015; Stratton 1998) and *Caenorhabditis elegans* (Gutteling *et al.*
65 2007), because genetically isogenic individuals derived by repeated inbreeding permit
66 a given genotype to be exactly repeated in multiple environments. Recently, the wild
67 relatives of model organisms have increasingly been exploited by evolutionary
68 biologists to understand adaptation and speciation (Clauss & Koch 2006; Mitchell-
69 Olds 2001). However, one disadvantage of non-model plants with outcrossing mating
70 systems is that they cannot usually be exploited to produce the genetically
71 homogeneous or inbred recombinant lines that enable researchers to study the reaction
72 norms of single genotypes in multiple environments (Dorn *et al.* 2000) or to map
73 novel QTLs in previously-genotyped lines (Alonso-Blanco *et al.* 2005). This
74 disadvantage could be compensated for by using cutting techniques to produce
75 multiple clones from single genotypes (Sultan & Bazzaz 1993; Waitt & Levin 1993;
76 Wu 1998). This method is only applicable to plants capable of vegetative propagation,
77 and it also needs relatively large plant bodies to produce many replicate clones.
78 Another technique applicable to a wider range of plants with relatively small starting
79 plant material is tissue culture (George & Sherrington 1984). However, tissue culture
80 has been exploited rarely for studies on the genetic basis of genotype–environment

81 interaction, and the few existing studies (Glock 1989; Glock & Gregorius 1986)
82 focused only on callus characteristics as target phenotypes. One potential issue that
83 should be carefully considered is that tissue-culture derived microshoots can express
84 phenotypic, “somaclonal” variation (Larkin & Scowcroft 1981) or may sometimes
85 show aberrant morphology and physiology *in vitro* (Joyce *et al.* 2003). This
86 somaclonal variation resembles that induced by physical mutagens, with elevated
87 levels of chromosome breakage and rearrangement, polyploidy, aneuploidy,
88 transposon activation and point mutation (D' Amato & Bayliss 1985). Therefore, with
89 a view to exploiting the techniques of tissue culturing more widely in studies of
90 genotype–environment interaction in outcrossing plants, it is necessary to extend our
91 knowledge on how propagation by tissue culture generates variation in phenotypes
92 that are relevant to adaptation in natural environments, compared to other sources of
93 genetically-related replicates such as outbred siblings.

94

95 Key plant properties that have attracted marked attention in the field of adaptation to
96 various environments are stress tolerances (e.g. Hong & Vierling 2000; Kwon *et al.*
97 2007; Lexer *et al.* 2003; Quesada *et al.* 2002; Steponkus *et al.* 1998; Zhang *et al.*
98 2004; Zhen & Ungerer 2008). One trait that can be used to indicate tolerance against
99 various physical stressors in plants is photosynthetic performance. Photosystem II
100 (PSII) activity is sensitive to both biotic and abiotic factors (Murchie & Lawson 2013).
101 Chlorophyll fluorescence can be used to determine the maximum efficiency with
102 which light absorbed by pigments of photosystem II (PSII) is used to drive
103 photochemistry in dark- (F_v/F_m) or light- (F_v'/F_m') adapted material and the operating
104 efficiency of PSII (Φ_{PSII}). It is a reliable indicator of photoinhibition and damage to
105 the photosynthetic electron transport system (Maxwell & Johnson 2000; Quick & Stitt

106 1989). Changes in chlorophyll fluorescence have been used in *Arabidopsis thaliana*
107 to quantify tolerance to cold and freezing temperatures. Ehlert and Hinch (2008)
108 showed that chlorophyll fluorescence imaging detected difference in freezing
109 tolerance between two *A. thaliana* lineages both before and after cold acclimation.
110 Mishra *et al.* (2014) applied chlorophyll fluorescence imaging for nine *A. thaliana*
111 lineages under cold and freezing temperature and suggested that freezing tolerance of
112 lineages could be screened by chlorophyll fluorescence under cold (4 °C) condition
113 without exposing plants to sub-zero temperature. Chlorophyll fluorescence have also
114 been used to study tolerance to drought (Bresson *et al.* 2015; McAusland *et al.* 2013;
115 Woo *et al.* 2008), and salt and heavy-metal stress (Yuan *et al.* 2013) in *A. thaliana*, as
116 well as in various other plants for tolerance or response to cold and freezing
117 temperatures (Baldi *et al.* 2011; Heo *et al.* 2014; Khanal *et al.* 2015; Medeiros *et al.*
118 2012; Xie *et al.* 2015), drought (Jansen *et al.* 2009) and salt (Yuan *et al.* 2013). If
119 variation in chlorophyll fluorescence can be properly estimated using tissue-culture
120 derived clones, therefore, this method would enhance studies in genotype–
121 environment interaction for stress tolerance in outcrossing plants.

122

123 To this end, we have studied change in chlorophyll fluorescence following cold shock
124 in a wild relative of a model plant species. *Arabidopsis lyrata* ssp. *petraea* is a close
125 relative of the model species *A. thaliana*, but with a different ecology, life history and
126 population genetics (Charlesworth *et al.* 2003; Davey *et al.* 2008; Davey *et al.* 2009;
127 Kuittinen *et al.* 2008; Kunin *et al.* 2009). Whilst *A. thaliana* is mainly selfing, with a
128 low level of genetic diversity within a population, *A. lyrata* ssp. *petraea* is outcrossing,
129 with a high level of genetic diversity even within a population (Clauss & Mitchell-
130 Olds 2006; Heidel *et al.* 2006; Kunin *et al.* 2009; Schierup *et al.* 2008). Further

131 studies on genetic and phenotypic variation in spatially distinct individuals and in
132 closely-related plants will clarify whether or not locally advantageous alleles are fixed
133 and if local populations are in evolutionary equilibrium, and are thus important in our
134 understanding of the evolutionary responses to environmental change. Distinguishing
135 phenotypic variation among closely related individuals from measurement errors is
136 difficult; however, this becomes possible if we can quantify the error within the same
137 genotype using tissue-cultured clones.

138

139 In this study, we measured the chlorophyll fluorescence parameters F_v/F_m , F_v'/F_m' and
140 Φ_{PSII} before and after cold shock, as an index of cold response, for seedlings from
141 three families from geographically isolated populations of *A. lyrata* ssp. *petraea*, and
142 tissue cultured plantlets derived from several genotypes (seeds) in each of those
143 families (Table 1). In order to evaluate the usefulness of tissue culture for obtaining
144 genetically homogenous replicates and to assess how much adaptively-relevant
145 variation exists within the species, we tested whether (i) among-genotype phenotypic
146 variation could be detected with the help of replication of tissue cultured plantlets, (ii)
147 somaclonal variation would remain in the range of other components of variation such
148 as within-family variation of seedlings, (iii) phenotypic variation in putatively
149 adaptive traits would exist between families and (iv) tissue-culturing affected these
150 measurements of chlorophyll fluorescence.

151 Material and Methods

152 *Plants*

153

154 Seeds of *Arabidopsis l. petraea* were collected from geographically separated
155 populations in Ardal (Norway) (61°19'25"N, 7°50'00"E, alt. 63 m), Notsand

156 (Sweden) (62°36'31"N, 18°03'37"E, alt. 3 m) and Sandfell (Iceland) (64°04'14"N,
157 21°41'06"E, alt. 123 m). No specific permits were required for the seed collection for
158 this study because these locations were not privately owned or protected in any way
159 and because the species was not protected in these countries. The species is a
160 perennial herb and keeps leaves throughout the year. We used a family of seeds that
161 were at least half-siblings, from one mother plant in each population. We grew 28–40
162 seedlings per family and in each case derived 44–69 tissue-cultured plantlets from 2–3
163 seeds (1 genotype = cloned plantlets from one seed) of each family.

164

165 *Tissue culture*

166

167 Seeds were sterilised in 10% commercial bleach for 20 min, washed in sterile water
168 and stored at 4°C overnight. The seeds were then placed onto 50% strength Murashige
169 and Skoog (MS) medium (Melford Laboratories Ltd, Ipswich, UK), pH 5.7,
170 supplemented with 1 % sucrose, 5 mg/L silver thiosulphate and solidified with 1 %
171 plant agar (Melford Labs. Ltd). The agar plates were held vertically, allowing for
172 maximum recovery of root tissue. After 4 weeks the root systems were excised and
173 placed intact onto Callus Induction Medium (CIM) (Clarke *et al.*, 1992) solidified
174 with 0.55% plant agar. Plates were incubated at 23 °C for 3 days then the roots were
175 cut into 5 mm lengths and placed in bundles on fresh CIM plates that were further
176 incubated at 20°C for 2–3 days. The root sections from each plant were re-suspended
177 in 10 ml molten Shoot Overlay Medium (SOM) (Clarke *et al.*, 1992) solidified with
178 0.8 % low gelling-temperature agarose and poured over a single 90 mm plate of Shoot
179 Induction Medium (SIM) (Clarke *et al.*, 1992) solidified with 0.55 % plant agar and
180 lacking antibiotics. The plates were incubated at 20 °C under a 16-hour day length.

181 Once shoots started to form from the calli they were transferred to 50 % strength MS
182 medium, pH5.7, supplemented with 1 % sucrose and solidified with 0.55% plant agar,
183 such that each plate contained 9 clones of the same genotype. A total of 4–9 plantlets
184 survived per plate. Each plate was treated as a block in the following experiment.

185

186 *Seedling growth*

187

188 Seeds were sown in Levington M3 compost within individual plug trays. Families
189 were randomised within each tray and trays were randomly repositioned every other
190 day. Plants were watered from the base of the pot as required with reverse-osmosis
191 (RO) purified water. No additional nutrients were added to the soil or water. Plants
192 were established to 6–8 leaf stage in controlled-environment growth cabinets
193 (Convion Controlled Environments Limited, Canada) set to a 12/12 hour day/night
194 cycle, 20/15 °C day/night, 70 % humidity; atmospheric CO₂ concentration was 400
195 ppm and photosynthetically-active radiation 250 μmol m⁻² s⁻¹. Chlorophyll
196 fluorescence measurements were taken just prior to and after a 24 hour cold treatment
197 in which plants were exposed to the same conditions as above, apart from the
198 temperature being decreased to 3 °C. 4–8 seedlings from the same family that were
199 tested together were treated as a block in the following experiment.

200

201 *Chlorophyll fluorescence*

202

203 Pre-cold and post-cold treatment measurements of chlorophyll fluorescence were
204 obtained using a chlorophyll fluorescence imager using Fluorimager software
205 (Technologica Ltd., Colchester, UK). Each block of plants was dark adapted for at

206 least 15 minutes before the maximum efficiency of photosystem II (F_v/F_m) was
207 measured to a blue light pulse at $3000 \mu\text{mol m}^{-2} \text{s}^{-1}$ for 200 ms. Following this pulse,
208 the plants were exposed to an actinic light of $150 \mu\text{mol m}^{-2} \text{s}^{-1}$ for six minutes,
209 followed by pulses of $3000 \mu\text{mol m}^{-2} \text{s}^{-1}$ for 200 ms to obtain measures of maximum
210 efficiency of photosystem II (F_v'/F_m') of light-adapted plant material and the
211 operating efficiency of photosystem II (Φ_{PSII}) in light-adapted plant material. Mean
212 values of F_v/F_m , F_v'/F_m' and Φ_{PSII} for each plant were taken from the image of each
213 whole plant.

214 All phenotypic data are available in Dryad Digital Repository:

215 <http://dx.doi.org/10.5061/dryad.xxxxx>.

216

217 *Statistical analyses*

218

219 To examine the relative importance of among-family and among-genotype variation
220 in cold response, we used nested ANOVA to partition the total variance in the
221 difference in each chlorophyll fluorescence measurement (F_v/F_m , F_v'/F_m' or Φ_{PSII})
222 induced by cold shock:

223 $P \sim \text{Family/Genotype/Block}$

224 for tissue culture material, or

225 $P \sim \text{Family/Block}$

226 for seedlings, where P is the difference in each type of chlorophyll fluorescence for a
227 plant individual between two measurements (i.e. value after cold shock minus that
228 before cold shock), the '/' symbol implies nesting and terms were fitted as fixed
229 effects. Variance in P was partitioned such that:

230 $\text{Total variance} = V(\text{Family}) + V(\text{Genotype}) + V(\text{Block})$

231 for tissue culture material, or

232 Total variance = V (Family) + V (Block)

233 for seedlings.

234 We did this analysis separately for the tissue-cultured plants and seedlings, in order to
235 evaluate variation in each natural and tissue-cultured condition. We conducted these
236 variance component analyses using the varcomp function in the ape library and the
237 lme function in R 2.8.0 (R Development Core Team 2008).

238

239 We tested whether variance in the change of F_v/F_m , F_v'/F_m' or Φ_{PSII} due to cold
240 shock among tissue-culture derived plantlets within each genotype was different from
241 that in seedlings of half-siblings of the same family using Bartlett tests. Because the
242 number of blocks differed between seedlings and tissue-cultured plantlets (Table 1),
243 we checked first whether the difference in the number of blocks affected the variance,
244 by re-sampling all possible combinations of 4 blocks from the 10 blocks of half-
245 siblings in Ardal and Notsand. Reducing block number changed the original variance
246 for 10 blocks only $< \pm 3\%$ without systematic bias.

247

248 Finally, we evaluated the effect of several factors on each type of chlorophyll
249 fluorescence measurement before and after cold treatment. We constructed the
250 following linear mixed-effect model, in which plant individual was treated as a
251 random effect:

252 $CF = I|B/P + C + T + F + C \times T + T \times F + C \times F + C \times T \times F$

253 where CF was a single measurement of either F_v/F_m , F_v'/F_m' or Φ_{PSII} and I|B/P was
254 the intercept with random effects of block, and individual plant nested in each block,
255 C was a categorical variable of cold shock (cold-shocked or not), T was a categorical

256 variable of tissue culture (tissue-cultured or not) and F was a categorical variable of
257 family (3 families), followed by the interaction terms among those variables. The
258 effect of each term was estimated by the lme function using the statistical software R
259 2.8.0 (R Development Core Team 2008). Akaike's Information Criterion (AIC) was
260 compared between the full model and a model lacking each term in a stepwise manner
261 and the best model with the lowest AIC was selected, followed by testing the
262 significance of each selected parameter using the Wald test.

263

264 Results

265 *Variance components in cold-response of F_v/F_m , F_v'/F_m' and Φ_{PSII}*

266

267 In the seedlings, the changes in F_v/F_m , F_v'/F_m' or Φ_{PSII} following cold treatment
268 varied significantly among families, explaining 4.9–9.1 % of the total variance (Table
269 2). For the tissue-cultured plantlets, the change in those indices following cold
270 treatment did not vary significantly among families, but did vary significantly among
271 genotypes within family, this component explaining 8.5–31.5 % of the total variance.
272 The within-block (error) variance component for tissue-cultured plantlets was 61.7–
273 81.8 % and tended to be smaller than this component for seedlings (89.1–92.2 %).

274

275 *Evaluation of somaclonal variation in comparison to within-family variation*

276

277 Variances in the change of F_v/F_m , F_v'/F_m' or Φ_{PSII} among clones within genotype
278 were clearly smaller than those among half-siblings of the same family in the Sandfell
279 family. Most genotypes had significantly smaller variances in F_v/F_m , F_v'/F_m' and Φ_{PSII}
280 than half-sibs as shown by the Bartlett test (Fig. 1). Similar patterns were observed in

281 Notsand and Ardal. No studied genotype had larger variance among clones than the
282 variance among half-siblings in any family.

283

284 *Effects of cold shock, tissue culturing and family on F_v/F_m , F_v'/F_m' and Φ_{PSII}*

285

286 All single effects of cold shock, tissue culture and family and all possible interaction
287 combinations among them affected F_v/F_m and F_v'/F_m' , and all such effects except the
288 3-way interaction between cold shock, tissue culture and family affected Φ_{PSII} ,
289 according to the best model (Table 3) based on Akaike's Information Criterion (AIC).
290 Cold shock and family were the strongest single effects. The interaction between these
291 two factors was also found to change all three measurements of chlorophyll
292 fluorescence, indicating that the effect of cold shock depended on family. The effect
293 of tissue culture was relatively small and not significant for any of the chlorophyll
294 fluorescence measures. We found substantial interactions between tissue culture and
295 family and interactions among cold shock, tissue culture and family, indicating that
296 the effect of tissue culture varied among families.

297

298 Discussion

299

300 *Among-genotype variance*

301

302 We were able to test for among-genotype variance using replicates generated by tissue
303 culture within genotypes and we detected such variance in F_v/F_m , F_v'/F_m' and Φ_{PSII}
304 measurements (Table 2). On the other hand, we showed significant but low
305 somaclonal variation. The within-block (error) variance component for tissue-cultured

306 plantlets was relatively small compared to that for non-tissue-cultured seedlings
307 (Table 2). The Bartlett tests showed that somaclonal variation was smaller than, or at
308 least remained within the range of, the within-family variance, which is the smallest
309 naturally observed component of variation in the hierarchy of genetic structure (Fig.
310 1). In *A. thaliana*, studies of natural variation have focused mainly on between-
311 population variation (e.g. Shindo *et al.* 2007). In contrast, *A. lyrata* has substantial
312 within-population variation, for example in the composition of glucosinolates (Clauss
313 *et al.* 2006) or self-incompatibility genes (Schierup *et al.* 2008). In this paper, we
314 showed that there is within-family as well as among-family, and thus among-
315 population, genetic variation in *A. lyrata* ssp. *petraea*. Within-family genetic variance
316 was relatively large in Sandfell (Iceland). The observed within-family genetic
317 variances in putatively adaptive traits highlight the wide potential for evolutionary
318 adaptation of the species and further validate the usefulness of relatives of model
319 organisms in evolutionary biology (Clauss & Koch 2006; Mitchell-Olds 2001).

320

321 *Among-family variance*

322

323 There was significant or marginally significant among-family variance in the change
324 of F_v/F_m , F_v'/F_m' and Φ_{PSII} values following cold treatment for seedlings (Table 2).
325 We used different growth chambers for plant growth and for cold shock and therefore
326 light condition for cold shock inevitably differed from that for growth. Light and
327 temperature are difficult to disassociate in such a study system, and both the single
328 effect of cold treatment and the light–temperature interaction can be involved in the
329 effect of cold shock. In *A. thaliana*, the change in chlorophyll fluorescence from
330 before to after cold shock correlates with tolerance to sub-zero temperatures measured

331 by electrolyte leakage and, therefore, this is regarded as an indicator of cold tolerance
332 or response (Ehlert & Hinch 2008; Mishra *et al.* 2014). Therefore, our result also
333 represents evidence for among-family (thus possibly among-population) variance in
334 cold response.

335

336 *Effects of tissue culturing*

337

338 We detected genotype-specific effects of tissue culture on F_v/F_m , F_v'/F_m' and Φ_{PSII}
339 (Table 3, Supplementary Table 1). This is consistent with a previous report of a
340 genotype-specific effects on callus characteristics (Glock 1989; Glock & Gregorius
341 1986). The three measured parameters of chlorophyll fluorescence all decreased after
342 the cold shock (the effects of cold shock in Table 3 are all negative for F_v/F_m , F_v'/F_m'
343 and Φ_{PSII}), indicating a decrease in photosystem II activity, as reported in previous
344 studies (Finazzi *et al.* 2006). A positive effect of interaction between tissue culture
345 and cold shock for Φ_{PSII} suggests that tissue-cultured plants were less affected by cold
346 shock than seedlings, and an interaction between tissue culture, cold shock and family
347 suggests that the extent to which tissue-cultured plants were less affected by cold
348 shock differed among families. Any differences among families in traits related to
349 responses to the tissue-culture environment, including root-cutting, callus formation
350 and growth on medium, might explain these observed interactions between tissue
351 culture and family. This finding is consistent with the report that somaclonal variation
352 is genotype-dependent and influenced by both the explant source and the tissue-
353 culture protocol (George & Sherrington 1984), and with a recent study showing that
354 the effect of tissue culture on somatic mutations depended on genotype (Zhang *et al.*
355 2010). The effects of tissue culture–genotype interaction, however, were comparable

356 to, or much smaller than the single effect of family (Table 3), indicating that such
357 interactions would not mask the single effect of genotype. The interaction effect
358 between tissue culture and family was much smaller in Φ_{PSII} than in F_v/F_m or F_v'/F_m'
359 (the ranges between maximum and minimum estimates were $0.043 - (-0.005) =$
360 0.048 , $0.082 - 0 = 0.082$ and $0.181 - 0 = 0.181$, respectively; Table 3). An interaction
361 between cold shock, tissue culture and family was detected only in F_v/F_m and F_v'/F_m' .
362 Also, the relative impact of among-genotype variance was smaller for Φ_{PSII} (8.5% of
363 the total variance, Table 2) than for F_v/F_m (31.5 %) or F_v'/F_m' (10.9 %). These results
364 imply that, although the maximum efficiencies of photosynthesis for dark- (F_v/F_m)
365 and light-adapted leaves (F_v'/F_m') were affected by tissue culturing in genotype-
366 specific ways, the actual electron transport operating efficiency (Φ_{PSII}) was less
367 affected by tissue culture.

368

369 *Conclusion*

370 Overall, we successfully detected among-genotype variance, with low somaclonal
371 variation, indicating that the advantage of tissue culturing in generating genetically
372 isogenic replicates exceeded its disadvantage in amplifying somaclonal variation in
373 our study system. We detected interaction effects of tissue culture with genotype for a
374 putatively adaptive trait, cold response; however, such variation would not mask the
375 single effect of genotype. Therefore, although one should consider effects of tissue
376 culturing carefully when interpreting any results relying on the technique, tissue
377 culturing is a useful method for obtaining genetically homogenous replicates in this,
378 and probably other non-model organisms. It can provide critical additional power
379 when studying phenotypes such as cold response related to adaptation in natural

380 environments, the variation in the phenotypes among families or populations, the
381 reaction norms of a genotype or the QTLs accounting for phenotypes.

382

383 Acknowledgements

384 We are grateful to Prof. M. Burrell for advice, Dr. P. Vergeer for providing seeds and
385 Dr. C. Lilley and Ms. J. Hibbard for providing tissue culture protocols. This research
386 was funded by the Natural Environment Research Council Post-Genomics and
387 Proteomics programme (NE/C507837/1) in UK; the Special Coordination Funds for
388 Promoting Science and Technology from the Ministry of Education, Culture, Sports,
389 Science and Technology of the Japanese Government (MEXT); and research
390 exchange program between Japan and UK by Japan Society for the Promotion of
391 Science (10037611-000065).

551

552 Figure. 1. Change in chlorophyll fluorescence (F_v/F_m , F_v'/F_m' and Φ_{PSII}) in seedlings
 553 or plantlets originating from Norway (Ardal), Sweden (Notsand) and Iceland
 554 (Sandfell) after cold-treatment (*values after shock – those before shock*). *, ** and
 555 *** = $P < 0.05$, $P < 0.01$ and $P < 0.001$, respectively, (Bartlett test) indicate a
 556 significantly lower variance of the genotype than among half-siblings in the same
 557 family. Three F_v/F_m values (0.340, 0.375, 0.592) and an F_v'/F_m' value (0.354) in

558 Sandfell half-siblings were out of the vertical ranges shown but were included in the
559 statistical tests.
560

561 Tables

562 Table 1. Numbers of plants and blocks in each family (Ardal, Notsand and Sandfell).

563 Plants were either seedlings in a half-sibling family or tissue-cultured clonal plantlets

564 from genotypes derived from a seed from each family. Block refers to the groups of

565 plantlets from each genotype, or groups of seedlings from the same family for half-

566 sibling families, that were treated and measured at the same time.

	Genotype 1	Genotype 2	Genotype 3	Half sibs
Ardal				
Number of plants	33	36	–	40
Number of blocks	4	4	–	10
Plants / block (min – max)	6–9	9–9	–	4–4
Notsand				
Number of plants	13	31	–	40
Number of blocks	2	4	–	10
Plants / block (min – max)	5–8	4–9	–	4–4
Sandfell				
Number of plants	45	28	23	28
Number of blocks	5	4	3	4
Plants / block (min – max)	9–9	5–9	5–9	5–8

567

568

569 Table 2. Analysis of variance for change in F_v/F_m , F_v'/F_m' and Φ_{PSII} by cold treatment
 570 for non-tissue-cultured seedlings and tissue-cultured plantlets. Family and Block refer
 571 to variation among families and among blocks within families, respectively. Each
 572 Block was a group of seedlings from the same family for Seedling or group of
 573 plantlets from the same genotype for Tissue cultures. Error refers to variation among
 574 plants within blocks.

587 Supplementary Table 1. Akaike's Information Criterion (AIC) of each examined
588 linear mixed models for F_v/F_m , F_v'/F_m' and Φ_{PSII} with effects specified by "+". The
589 best model (top) with the lowest AIC was selected for each of F_v/F_m , F_v'/F_m' and Φ_{PSII}
590 and their details are shown in Table 3. C: cold shock (cold-shocked or not), T: tissue
591 culture (tissue-cultured or not), and F: family. "x" indicates interaction effects
592 between two or three variables. Delta indicates difference in AIC from the best model.
