10 Running title: metaldehyde-degrading bacteria in soils

11

1  
2  
3 12 **Summary**  
4  
5

6 13 Metaldehyde is a common molluscicide, used to control slugs in agriculture and  
7  
8 14 horticulture. It is resistant to breakdown by current water treatment processes, and its  
9  
10 15 accumulation in drinking water sources leads to regular regulatory failures in drinking water  
11  
12 16 quality. To address this problem, we isolated metaldehyde degrading microbes from  
13  
14 17 domestic soils. Two distinct bacterial isolates were cultured, that were able to grow  
15  
16 18 prototrophically using metaldehyde as sole carbon and energy source. One isolate belonged  
17  
18 19 to the genus *Acinetobacter* (strain designation E1) and the other isolate belonged to the  
19  
20 20 genus *Variovorax* (strain designation E3). *Acinetobacter* E1 was able to degrade  
21  
22 21 metaldehyde to a residual concentration less than 1 nM, whereas closely related  
23  
24 22 *Acinetobacter* strains were completely unable to degrade metaldehyde. *Variovorax* E3 grew  
25  
26 23 and degraded metaldehyde more slowly than *Acinetobacter* E1, and residual metaldehyde  
27  
28 24 remained at the end of growth of the *Variovorax* E3 strain. Biological degradation of  
29  
30 25 metaldehyde using these bacterial strains or approaches that allow *in situ* amplification of  
31  
32 26 metaldehyde degrading bacteria may represent a way forward for dealing with  
33  
34 27 metaldehyde contamination in soils and water.

## 30 Introduction

31 Metaldehyde ( $\text{CH}_3\text{CHO}$ )<sub>4</sub> is an ether, formed from a cyclic tetramerisation of acetaldehyde  
32 (Fig. 1A) (Kekulé and Zincke, 1872). Metaldehyde was initially used as a solid fuel firelighter  
33 “Meta-fuel” (Miller, 1928), but its major contemporary use is as a molluscicide in agriculture  
34 and horticulture. Its application in controlling slugs was known as early as 1934 (Gimingham,  
35 1940) and it is now widely used in both agricultural fields and domestic gardens. It is applied  
36 as a pelleted bran bait that inhibits slug feeding after exposure (Wedgwood and Bailey,  
37 1988), causing effects such as the distention and disintegration of the Golgi apparatus and  
38 endoplasmic reticulum in the mucus cells of slugs (Triebkorn et al., 1998).

39 In 2014, Metaldehyde accounted for 87 % of all recorded molluscicide applications on  
40 agricultural fields in the UK (Garthwaite et al., 2015). 112 tonnes were applied over 920  
41 thousand hectares (21 % of surveyed arable land used to grow crops) in Britain in 2014;  
42 primarily on wheat, oilseed rape and potato crops (Garthwaite et al., 2015). The vast  
43 majority of failures in drinking water quality in the UK, due to pesticide contamination, are  
44 caused by metaldehyde exceeding the regulatory limit of 0.1 µg/L ( $\approx 0.6$  nM) (European  
45 Union Council Directive 98/83/EC) (Fig. 1B).

46 The recalcitrance of metaldehyde to degradation at ambient temperature (Fleischmann et  
47 al., 2000) is problematic for water treatment, as metaldehyde is not removed by  
48 conventional water treatment processes (Kay et al., 2014). Researchers are pursuing a  
49 variety of chemical and physical approaches to deal with the problem of metaldehyde  
50 contamination (Autin et al., 2013; Doria et al., 2013; Tao and Fletcher, 2013; Tao and  
51 Fletcher, 2014). But currently, no economical method exists to degrade or remove  
52 metaldehyde from water.

1  
2  
3 53 It has been shown that the xenobiotic metaldehyde can be quickly degraded in soils (Zhang  
4  
5 54 et al., 2011) and is oxidised to carbon dioxide under aerobic conditions in unsterilised soils  
6  
7 55 (EFSA, 2010). This strongly suggests the involvement of microbes in its degradation,  
8  
9 56 although no microorganisms have been isolated to date that degrade metaldehyde. The  
10  
11 57 degradation of metaldehyde to CO<sub>2</sub> is strongly exothermic (heat of combustion 3370 kJ.mol<sup>-1</sup>  
12  
13 58 <sup>1</sup> (Fleischmann et al., 2000)), suggesting that it has the potential to be a carbon and energy  
14  
15 59 source to support microbial growth. Soils are home to a vast array of microbes and  
16  
17 60 represent a source of metabolic activities that may be of use in industrial and medicinal  
18  
19 61 applications (Delmont et al., 2011). Here we enriched microbes from soils, and report the  
20  
21 62 first isolation and identification of microbial isolates capable of using metaldehyde as a sole  
22  
23 63 source of energy and carbon for growth.

2  
3 66 **Results and Discussion**  
4  
5

6 67 Two distinct metaldehyde degrading strains were isolated from domestic soils  
7

8 68 Metaldehyde degrading bacteria were selected in a mineral medium consisting of salts  
9

10 69  $\text{Na}_2\text{HPO}_4$  (55 mM),  $\text{KH}_2\text{PO}_4$  (11 mM),  $\text{NH}_4\text{Cl}$  (6 mM) and  $\text{MgSO}_4$  (0.4 mM) (pH 7). This was  
11

12 70 supplemented with 2 ml/l of a trace elements solution (Vishniac and Santer, 1957).  
13

14 71 Metaldehyde was provided as sole carbon source and control cultures lacked metaldehyde.  
15

16 72 Ability to grow using metaldehyde was tested in both liquid enrichment cultures and on  
17

18 73 solid media, containing 1.5 % agarose. 100 ml liquid cultures were inoculated with 1 g of soil  
19

20 74 obtained from domestic gardens in York, UK. Cultures were incubated at 30°C for 3 days, 1  
21

22 75 ml of enrichment media was sub-cultured into fresh media and incubated for a further 3  
23

24 76 days, and subsequently samples were spread onto agarose plates containing 2800  $\mu\text{M}$  (500  
25

26 77 mg/L) metaldehyde. 50-200 colonies were obtained on plates when the enrichments were  
27

28 78 carried out in liquid culture in the presence of 570  $\mu\text{M}$  (100 mg/L) metaldehyde, but not  
29

30 79 following control enrichments in the absence of metaldehyde. 1 g samples of the same  
31

32 80 domestic soils were re-suspended in 10 ml of sterile water and 100  $\mu\text{L}$  aliquots spread  
33

34 81 directly onto agarose plates containing metaldehyde. 2-5 colonies grew on these plates. The  
35

36 82 morphology of all the colonies was white, round and glossy. Ten isolates were picked for  
37

38 83 further analysis, and named E1-E6 and M1-M4, to designate the source soils used. Soil E had  
39

40 84 a recent history of metaldehyde utilization, whereas soil M had not been treated with  
41

42 85 metaldehyde for at least 5 years. In each case the isolated strains grew on agarose plates  
43

44 86 supplemented with metaldehyde, but not in its absence, suggesting they were utilizing  
45

46 87 metaldehyde as a carbon and energy source.  
47

58  
59  
60

1  
2  
3 89 On subculturing the metaldehyde-degrading strains, each strain appeared to be a pure  
4  
5 90 culture, except strain E4 which yielded two distinct colony morphologies, and was  
6  
7  
8 91 subsequently subdivided into E4a and E4b. Colonies from strains E1, E3, E4a, E4b, E5, M1  
9  
10 92 and M4 were used for amplification of 16S rDNA as described previously with primers U8F  
11  
12 93 and U1492R (Eden et al., 1991). Amplification was achieved using GoTaq polymerase  
13  
14  
15 94 (Promega) with a standard programme of: 98°C for 30 s; 35 cycles of 98°C for 10 s, 50°C for  
16  
17 95 30 s, 72°C for 60 s; 72°C for 10 min. PCR products were purified using QIAquick PCR  
18  
19 96 purification kit (Qiagen) following the manufacturer's instructions. For Restriction Fragment  
20  
21 97 Length Polymorphism (RFLP) analysis, 1 µg of purified DNA was digested for 1 or 3 hours at  
22  
23 98 37°C using restriction enzyme HhaI. RFLP revealed two distinctly different ribotypes (see  
24  
25 99 Supporting Information). Two examples of each ribotype were sequenced. Sanger  
26  
27  
28  
29 100 sequencing was used to obtain the nucleotide sequences of the U8F-U1492R amplicons of  
30  
31 101 E1, M1, E3 and E4a using U8F as sequencing primer. Sequences from E1 and M1 were  
32  
33  
34 102 aligned using ClustalX V2.1 and found to be identical across the >900 base region where the  
35  
36 103 base sequence could be confidently assigned. Similarly, the sequences from E3 and E4a  
37  
38 104 were found to be identical across a >900 base region.  
39  
40  
41 105 Subsequent investigation focused on the strains E1 and E3. The sequences of E1 and E3 (see  
42  
43 106 Supporting Information) type strains of *A. pittii*, *A. oleivorans*, and *A. seifertii* also had 99%  
44  
45 107 identity to E1. The E3 sequence has 99% identity to type strains of *Variovorax*  
46  
47  
48 108 *boronicumulans*, *V. paradoxus*, *V. guangxiensis*, *V. ginsengisoli*. Based on these analyses, the  
49  
50 109 isolates have been assigned genera and designated *Acinetobacter* E1 and *Variovorax* E3.  
51  
52  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 110 The disappearance of metaldehyde from minimal media is proportional to the growth of  
4  
5 111 *Acinetobacter* E1 and *Variovorax* E3 in pure cultures  
6  
7 112 Triplicate cultures of *Acinetobacter* E1 and *Variovorax* E3 were grown in minimal media with  
8  
9  
10 113 850  $\mu\text{M}$  (150 mg/L) metaldehyde, incubated at 30°C with shaking at 200 rpm. An additional  
11  
12 114 3 flasks of media were not inoculated. Periodic samples were taken from each culture and  
13  
14  
15 115 an uninoculated media flask and OD<sub>600</sub> measurements were made. Contemporaneously,  
16  
17 116 cellular material was removed from samples by centrifugation at 5,000  $\times$  g, the supernatant  
18  
19 117 aspirated and stored at -20°C for later analysis of metaldehyde content. Growth curves are  
20  
21 118 shown in Fig. 2A. During the exponential growth phase, *Acinetobacter* E1 had a doubling  
22  
23 119 time of 8.5 hours, and *Variovorax* E3 had a doubling time of c. 22 hours. There was no  
24  
25 120 increase in optical density in the uninoculated control culture. Metaldehyde concentration  
26  
27 121 of culture media samples was quantified by Liquid Chromatography-Mass Spectrometry (for  
28  
29 122 method, see Supporting Information). Metaldehyde disappeared over a similar timescale to  
30  
31 123 the growth of the E1 and E3 isolates (Fig. 2B). The disappearance of metaldehyde from the  
32  
33 124 cultures was correlated with the growth of the isolates (Fig. 2C & D). As the sole carbon and  
34  
35 125 energy source present in the culture medium it can be concluded that the strains were  
36  
37 126 catabolising metaldehyde for growth. *Variovorax* E3 catabolises metaldehyde more slowly,  
38  
39 127 has a longer lag time, lower maximum optical density, longer doubling time and higher final  
40  
41 128 concentration of residual metaldehyde compared to *Acinetobacter* E1.  
42  
43  
44  
45

47  
48  
49  
50  
51  
52 130  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 131 Utilization of metaldehyde by *Acinetobacter* E1 is a property not shared by other

4  
5 132 *Acinetobacter*

6  
7 133 The remainder of the work focused on *Acinetobacter* E1 which has faster growth kinetics,

8  
9 134 and a more rapid and complete utilization of metaldehyde, compared to *Variovorax* E3.

10  
11 135 *Acinetobacter* E1 was unable to grow using glucose, fructose, arabinose or glycerol as

12  
13 136 alternative carbon substrates.

14  
15  
16  
17 137 It was desirable to identify other strains related to *Acinetobacter* E1 for comparative

18  
19 138 purposes. *A. calcoaceticus* RUH 2202 (Nemec et al., 2011) was purchased from the Belgian

20  
21 139 Coordinated Collection of Microorganisms, *A. calcoaceticus* ANC3678 (Nemec et al., 2011),

22  
23 140 *A. calcoaceticus* NIPH1 (Nemec et al., 1999), *A. pittii* ANC3678 (Nemec et al., 2011) *A. pittii*

24  
25 141 70.29 (Seifert et al., 1994), and *A. baylyi* DSM14961 (Carr et al., 2003) from the CIP culture

26  
27 142 collection (Pasteur Institute, Paris). The ability of these *Acinetobacter* to use metaldehyde

28  
29 143 was assessed by streaking colonies from an LB plate onto a MSM + metaldehyde plate and

30  
31 144 inoculating into liquid media containing 850  $\mu$ M metaldehyde. There were no signs of

32  
33 145 growth in either media after 4 days' incubation at 30 °C. *Acinetobacter* E1, unlike strain RUH

34  
35 146 2202, was able to grow on phenol, whereas *A. calcoaceticus* RUH 2202 grew on 1 % ethanol

36  
37 147 as a carbon source, but strain E1 could not grow with ethanol. Both *Acinetobacter* strains E1

38  
39 148 and RUH 2202 grew on acetate as a carbon source, which allowed for comparative analysis

40  
41 149 of metaldehyde utilization under the same growth conditions. Following growth on acetate

42  
43 150 as sole carbon source, *Acinetobacter* E1 utilized 40  $\mu$ M metaldehyde over a 30 minute

44  
45 151 period, whereas there was no loss of metaldehyde in cultures of *A. calcoaceticus* RUH 2202

46  
47 152 (Fig. 3A).

48  
49  
50  
51  
52  
53  
54  
55  
56 153

1  
2  
3 154 *Acinetobacter* E1 degrades metaldehyde to completion, and this degradation is followed by  
4  
5 155 oxygen consumption  
6

7 156 Following growth on metaldehyde, *Acinetobacter* E1 utilized 40  $\mu$ M metaldehyde over a 12  
8  
9 157 minute period (Fig. 3A). This suggests a c. 2-fold increase in activity of the metaldehyde  
10  
11 158 degrading enzyme following culturing with metaldehyde. Furthermore, suspensions of  
12  
13 159 *Acinetobacter* E1 utilize oxygen in a metaldehyde-dependent manner after growth on  
14  
15 160 metaldehyde, but not after growth on acetate (Fig. 3B). This oxygen consumption is delayed  
16  
17 161 compared to metaldehyde disappearance, indicating that the metaldehyde catabolism  
18  
19 162 involves metaldehyde degradation, followed by an oxygen-dependent metabolic step. The  
20  
21 163 apparent  $K_M$  of cell suspensions of *Acinetobacter* E1 for metaldehyde was c. 50  $\mu$ M, and it is  
22  
23 164 noted that metaldehyde was degraded to below the limit of detection in these experiments  
24  
25 165 (<1 nM metaldehyde) in 30 minutes (Fig. 3C), which suggests that this or similar strains may  
26  
27 166 have value in future bioremediation strategies.  
28  
29  
30  
31  
32  
33

34 167 Metaldehyde is a xenobiotic (*i.e.* only in existence due to human activity via chemical  
35  
36 168 synthesis) that has been in widespread use for about 100 years. The metaldehyde degrading  
37  
38 169 strains *Acinetobacter* E1 and *Variovorax* E3 share evolutionary heritage with other bacteria  
39  
40 170 with versatile metabolism (Fewson, 1967; Willems et al., 1991) and a demonstrated ability  
41  
42 171 to degrade xenobiotics (Mirgain et al., 1993; Greene et al., 2000; Sorensen et al., 2005;  
43  
44 172 Wang and Gu, 2006; Bruland et al., 2009; Carbajal-Rodriguez et al., 2011; Zhang et al., 2012;  
45  
46 173 Rajoo et al., 2013; Murdoch and Hay, 2015) and other potentially recalcitrant chemicals  
47  
48 174 (Reisfeld et al., 1972; Abbott et al., 1973; Koh et al., 1985; Hwang and Draughon, 1994;  
49  
50 175 Singh and Lin, 2008; Zhao et al., 2009). The metabolic versatility of *Acinetobacter* and  
51  
52 176 *Variovorax* isolates varies between isolates, presumably due to horizontal acquisition of  
53  
54  
55  
56  
57  
58  
59  
60

1  
2  
3 177 genetic traits, selected in particular environments. Future work will focus on identifying the  
4  
5 178 mechanistic basis for metaldehyde degradation.  
6  
7

8  
9 179 To conclude, here we have demonstrated the first isolation of bacteria capable of degrading  
10  
11 180 the commonly used molluscicide metaldehyde. Metaldehyde is a stable polymer of  
12  
13 181 acetaldehyde which consists of a ring structure in which the bonds are aliphatic C-C single  
14  
15 182 bonds and C-O ethers. Biological degradation of metaldehyde via the metabolic processes in  
16  
17 183 bacteria such as *Acinetobacter* E1 and *Variovorax* E3 may prove valuable in dealing with  
18  
19 184 metaldehyde contamination in natural environments and drinking water sources.
