Abstract

The airway epithelium secretes proteins that function in innate defense against infection. BPI fold-containing family member A1 (BPIFA1) is secreted into airways and has a protective role during bacterial infections, but it is not known whether it also has an antiviral role. To determine a role in host defense against influenza A virus (IAV) infection and to find the underlying defense mechanism we developed transgenic mouse models that are deficient in BPIFA1 and used these, in combination with *in vitro* 3D mouse tracheal epithelial cell (mTEC) cultures, to investigate its antiviral properties. We show that BPIFA1 has a significant role in mucosal defense against IAV infection. BPIFA1 secretion was highly modulated after IAV infection. Mice deficient in BPIFA1 lost more weight after infection, supported a higher viral load and virus reached the peripheral lung earlier, indicative of a defect in the control of infection. Further analysis using mTEC cultures showed that BPIFA1-deficient cells bound more virus particles, displayed increased nuclear import of IAV ribonucleoprotein complexes and supported higher levels of viral replication. Our results identify a critical role for BPIFA1 in the initial phase of infection by inhibiting the binding and entry of IAV into airway epithelial cells.

1   Introduction

2   The airway epithelium has a fundamental role in the initial defense against

3   pathogens and as such secretes a number of proteins/peptides that function in

4   innate defense [1]. Bactericidal/permeability-increasing (BPI) fold-containing family A1

5   (BPIFA1; also called SPLUNC1) is a glycoprotein that is highly expressed in the

6   respiratory epithelium and submucosal glands of the upper airways in mice and

7   humans [2-9]. The mouse and human BPIFA1 sequences are homologous [8, 10, 11].

8   Previous studies have demonstrated that BPIFA1 acts as a surfactant [12], can

9   regulate the amiloride-sensitive epithelial sodium channel, ENaC [13] and affects

10   mucociliary clearance in the upper airways [14]. It has also been shown to have anti-

11   bacterial roles. For example, *Bpifa1* expression is induced after *Mycoplasma*

12   infection, enhancing IL-8 production and bacterial clearance [15]. BPIFA1 also has a

13   role in defense against *Klebsiella pneumoniae* [16], possibly acting through modulation

14   of macrophage function [17]. Less is known about any anti-viral role of BPIFA1,

15   although our previous work has shown modulation of BPIFA1 levels after murine γ-

16   herpesvirus 68 infection [18].

17   Influenza A virus (IAV) is an enveloped RNA virus of the Orthomyxovirus

18   genus. Seasonal influenza is a major cause of respiratory infection resulting in

19   substantial morbidity, mortality and thus economic burden worldwide [19]. Pandemic

20   influenza strains emerge sporadically as a result of genetic reassortment and are a

21   substantial global health concern [20]. There are vaccines and antiviral drugs to

22   combat influenza. However, due to rapid virus evolution, vaccines need to be re-

23   formulated and re-administered most years [21] and resistance against antiviral drugs

24   is emerging [22]. It is therefore important to understand how intrinsic and innate

25   mechanisms modulate influenza virus infection and how these may be used to

26   develop novel therapeutic interventions.

27   The negative-sense, single-stranded genome of IAV comprises eight

28   segments of viral RNA which are separately encapsidated into ribonucleoprotein

29   particles (RNPs) [23]. Infection and entry of IAV into cells involves viral attachment, via

30   the hemagglutinin (HA) glycoprotein that is embedded in the virion membrane, to cell

31   surface receptors that contain sialic acid [24]. After binding, virus particles enter the

32   cell by receptor-mediated endocytosis. Fusion of the virus membrane with the

33   endosomal membrane results in release of RNPs into the cytoplasm [24, 25] which are

34   then imported into the nucleus , where genome replication and transcription of viral

35   genes take place [26]. Understanding the entry process and how the host counters it is

36   critical to uncovering inhibitors with therapeutic potential.

37   In this study, we used transgenic mouse models combined with *in vitro* 3D-

38   culture systems to show that BPIFA1 has a role in the intrinsic defense against IAV

39   infection.

40

41   **Results**

42   **BPIFA1 expression after IAV infection.**

43   To determine changes in BPIFA1 levels following IAV infection, C57BL/6J mice were

44   infected intranasally (i.n.) with 10^3 pfu IAV X-31 (or as controls with *u.v.*-inactivated

45   virus or mock-infected) and analyzed at time-points post-infection (p.i.). IAV X-31 is

46   a mouse-adapted H3N2 strain that generates a sub-lethal infection [27]. It thus models

47   most of the IAV-associated disease in humans and also allows for analysis over an

48   extended time-course.

49   Firstly, levels of BPIFA1 in broncho-alveolar lavage (BAL) were accurately

50   quantified using (Wes™; ProteinSimple). The results (Fig. 1) showed BPIFA1 levels

51   decreased dramatically after infection (100-fold) to a nadir at day 7 p.i. before

52   returning to a level that was not significantly different to uninfected mice by day 14

53   p.i. *u.v.*-inactivated virus did not affect the levels of BPIFA1 as measured at day 5 p.i.

54   Next, the pattern and quantity of BPIFA1 staining was determined by

55   immunohistology (IH). In mock-infected mice, BPIFA1 was abundant in the

56   epithelium of the trachea and bronchi (Fig. 2A, B arrows) but present only within

57   scattered cells in the bronchioles (Fig. 2C, arrows) and absent in the surrounding

58   alveoli (Fig. 2C). Following infection with IAV, a substantial decrease in the number

59   of BPIFA1-positive cells was observed and confirmed by the quantitative analysis

60   that showed a 4 – 8-fold (p <0.05) decrease in the percentage area stained in the

61   trachea and bronchi respectively to day 7 p.i.; at this point, there were foci of erosion

62   with reduced cell height, loss of cilia, loss of cellular polarity and occasional loss of

63   epithelial cells. Recovery of levels of BPIFA1 and evidence of epithelial regeneration

64   with foci of multilayered epithelium and mitoses was seen by day 14 p.i. (Fig. 2A, B).

65   The intensity of BPIFA1 staining in the positive areas (i.e. in individual epithelial

66   cells) did not decrease significantly in the trachea, but in the bronchi a similar pattern

67   to that of area stained was noted with an initial decrease followed by a gradual

68   recovery. In contrast, in bronchioles the intensity of staining in epithelial cells

69   increased five-fold to day 14 p.i., whilst the number of positive cells (area stained)

70   increased three-fold by day 14 p.i. (Fig. 2C).

71

Mice deficient in BPIFA1 support higher levels of IAV replication.

To determine the role of BPIFA1 in defense against IAV, BPIFA1-deficient mice (*Bpifa1*$^{-/-}$) were generated as described in supplementary data and S1 Fig. (A). *Bpifa1*$^{-/-}$ mice expressed no detectable BPIFA1 protein in the lungs (S1 Fig. (B)), but did not exhibit any morphological changes or altered distribution of cell types in airways and alveoli (S1 Fig. (C); described in supplementary data).

C57BL/6J and *Bpifa1*$^{-/-}$ mice were infected i.n. with 10^3 pfu IAV X-31. The weight of the mice and lung virus titers were determined over a 28-day period. The results (Fig. 3A, B) showed that *wt* mice were readily infected with IAV. They lost weight (max. 5%; day 6 p.i.) before recovering. Titers of IAV increased in the lungs, peaking at 10^6 pfu/g tissue on day 5 p.i. Infection in *Bpifa1*$^{-/-}$ mice followed a similar course. Weight loss was significantly greater ($p < 0.01$) in *Bpifa1*$^{-/-}$ mice (12% at day 6 p.i.). In addition, IAV titers were significantly ($p < 0.05$) and at least 1 $\log_{10}$ higher at all time-points. Virus was not detectable in either group at days 7 and 14 p.i.

To control for potential developmental adaptation in the knockout mice, a club cell-specific, tamoxifen (tmx)-inducible conditional knockout mouse strain (*Bpifa1*^{loxP}; *Scgb1a1-CreER*^{TM}) was generated as described in the S1 text. Western blot analysis of lung tissue confirmed a 9-fold knockdown in the level of BPIFA1 in *Bpifa1*^{loxP}; *Scgb1a1-CreER*^{TM} mice after tmx treatment as compared with mice that were treated with carrier (Fig. 3C).

Bpifa1^{loxP}; *Scgb1a1-CreER*^{TM} mice were treated with either carrier (vegetable oil) or tmx and, along with untreated *Bpifa1*^{loxP}; *Scgb1a1-CreER*^{TM} and *Bpifa1*$^{-/-}$ mice, were infected i.n. with IAV. Virus titers in the lungs were determined at day 7 p.i. The results (Fig. 3D) showed that titers of infectious virus were significantly lower in untreated or carrier-treated mice than in tmx-treated *Bpifa1*^{loxP}; *Scgb1a1-CreER*^{TM}

97   mice or *Bpifa1*[-/-] mice. Thus, reduction of BPIFA1 expression using either total or

98   conditional knockout of BPIFA1 enabled IAV to be more pathogenic and replicate to

99   higher titers in the lungs of infected mice.

100

101   **BPIFA1 limits the initial spread of IAV *in vivo*.**

102   To assess whether BPIFA1 influenced the distribution of IAV infection, C57BL/6J

103   and *Bpifa1*[-/-] mice were infected and IAV-infected cells identified by IH. At day 1 p.i.,

104   IAV antigen was seen within, and adjacent to foci of necrotic respiratory epithelial

105   cells in the nasal cavity, trachea, bronchi and proximal bronchioles of both *wt* and

106   *Bpifa1*[-/-] mice (S2 Fig., arrows). However, in *Bpifa1*[-/-] mice, epithelial cells in the

107   distal bronchioles were found to be infected and macrophages in alveoli around the

108   infected bronchioles were positive for IAV (Fig. 4. arrows and red arrowheads

109   respectively). In contrast, IAV antigen was not observed in distal bronchioles and

110   alveoli of *wt* mice. At subsequent days post-infection there were no differences in the

111   distribution of IAV antigen between *wt* and *Bpifa1*[-/-] mice.

112   Thus, in the absence of BPIFA1, IAV infection reached the distal airways and

113   alveoli earlier during infection.

114

115   **BPIFA1 restricts IAV infection in normal epithelial cells.**

116   Given the differences in viral titer as early as day 1 p.i., we hypothesized that one

117   function of BPIFA1 could be to influence directly the infection of epithelial cells. To

118   investigate this, tracheal cell cultures were established from mice and cultured at the

119   air-liquid interface to generate well-differentiated cultures (mTEC) [28, 29]. The

120   validation of these cultures from *wt* mice is presented in supplementary data and S3

121   Fig. Differentiated mTEC ALI cultures displayed phenotypic features associated with

7

122　complex populations of cells including ciliated cells (β-tubulin, FoxJ1), BPIFA1,

123　mucin (MUC5B), and SCGB1A1 (CCSP)-expressing cells that matched with the

124　features of the native rodent airway epithelium. The cultures from *Bpifa1*[-/-] mice had

125　similar levels of ciliogenesis (β-tubulin staining) and mucin (MUC5B staining) to

126　those from *wt* counterparts (S4 Fig.). Quantification of β-tubulin-staining showed that

127　approx. 17% of cells were ciliated in both types of cultures. In *wt* cultures, 24% of

128　cells were BPIFA1 positive and were non-ciliated. Thus, mTEC ALI cultures are

129　highly representative of mouse airway epithelium and an ideal model to study the

130　role of BPIFA1 during infection.

131　　　mTEC ALI cultures from *wt* and *Bpifa1*[-/-] mice were infected with IAV (0.1

132　pfu/cell) and infection analyzed by immunofluorescence (IF). In *wt* mTEC ALI cells,

133　IAV antigen was observed predominantly in epithelial cells that did not express

134　BPIFA1, at both 24 and 48 h p.i. (Fig. 5B, C). An increased number of cells

135　containing IAV NP antigen was seen in *Bpifa1*[-/-] mTEC ALI cultures as compared

136　with *wt* cells at both time-points (Fig. 5E, F). Quantification revealed a >2-fold and

137　nearly 2-fold higher intracellular IAV NP load in *Bpifa1*[-/-] than in *wt* mTEC cultures at

138　24 h p.i. and 48 h p.i. respectively (Fig. 5G; *p* < 0.05). There was also a significant

139　increase in infectious IAV titer in apical wash fluid from *Bpifa1*[-/-] compared with *wt*

140　cells (Fig. 5H). Thus, BPIFA1 inhibits the infection of normal (mTEC ALI) cells by IAV

141　at a stage up to or before early viral gene expression.

142

143　**BPIFA1 limits the import of IAV into epithelial cells.**

144　Import of virus ribonucleoprotein (vRNP) complexes into the nucleus is one of the

145　initial steps of the IAV replication cycle. To investigate whether BPIFA1 influences

146　the early stages of IAV infection, day 14 mTEC ALI cultures were infected with IAV.

8

147 Import of RNP complexes into the nucleus was then assessed by

148 immunofluorescence analysis using anti-IAV NP. Blocking protein synthesis with

149 cycloheximide (CHX) was performed to distinguish imported RNPs from *de novo* NP

150 production. The amount of purified virus used was sufficient enable detection of RNP

151 import in 100% of cells in an equivalent assay performed on MDCK cells (data not

152 shown). The results (Fig. 6A, B) showed that in the absence of CHX, IAV NP was

153 readily observed 4 h after infection in the nuclei of cells from *wt* mice but, as with the

154 previous experiment, was present in 3.5x more nuclei in cells from *Bpifa1*$^{-/-}$ mice. In

155 the presence of CHX, RNP complexes were observed in the nuclei of 1% of *wt* cells

156 but in a significantly ($p < 0.05$) higher proportion (25x) of nuclei in *Bpifa1*$^{-/-}$ cells (Fig.

157 6A right panels, B, C). Thus BPIFA1 appreciably decreased the number of cells with

158 visible accumulation of IAV RNPs after infection, indicating that it acts at an early

159 stage of the viral life cycle.

160

161 **BPIFA1 inhibits IAV binding to respiratory epithelial cells.**

162 To determine if BPIFA1 affected virus binding, mTEC ALI cultures derived from

163 *Bpifa1*$^{-/-}$ and *wt* mice were incubated with Alexa Fluor 488-labelled IAV (IAV-488)

164 and bound virus was assessed by confocal microscopy. The amount of labelled virus

165 used was sufficient to enable detection of binding in 100% of cells in an equivalent

166 assay performed on MDCK cells (data not shown). *wt* cells showed IAV binding

167 predominantly to the surface of Foxj1-positive (ciliated) cells that were negative for

168 BPIFA1 (Fig. 7A). The BPIFA1-positive sub-population of cells (non-ciliated; S3 Fig.

169 A, C) presented as focal clusters in mTEC ALI cultures (outlined in yellow) and were

170 predominantly free from IAV-binding (Fig. 7A). Analysis of the distribution of α2,3-

171 linked and α2,6-linked sialic acid residues using the lectins MAA and SNA

172   respectively showed that there were numerous cells with α2,3-linked residues on the

173   cell surface in both *wt* and *Bpifa1*^{-/-} cultures (mean *n* = 3; 25% and 22% respectively)

174   and that these were on the BPIFA1-negative cells (S5 Fig. (A)). The few α2,6-

175   positive cells present in the *wt* and *Bpifa1*^{-/-} cultures (mean *n* = 3; 3% and 5%

176   respectively) were mostly BPIFA1-positive (S5 Fig. (B - E)). Quantification of bound

177   IAV-488 showed that the integrated fluorescence intensity from *Bpifa1*^{-/-} cells was 4

178   fold greater than that from *wt* cells (Fig. 7B, C). Thus, our data show that IAV bound

179   predominantly to ciliated cells that were BPIFA1-negative, α2,3-linked sialic acid-

180   positive, and that the presence of BPIFA1 decreased the binding of IAV to these

181   cells.

182

183

Discussion

184

185   BPIFA1 is constitutively expressed and secreted by the airway epithelium [2, 6,

186 [7, 18, 30, 31] including the submucosal glands [9, 28, 30, 31]. However, its precise biological

187 functions remain elusive. Our studies have uncovered an important role for BPIFA1

188 in the host defense against IAV infection. BPIFA1 levels were modulated after

189 infection and genetic knockout of BPIFA1 led to a higher viral titer both *in vivo* and in

190 mTEC ALI cultures. There was also greater nuclear import of virus RNP complexes

191 and binding of virus to cells in mTEC cultures lacking BPIFA1.

192   BPIFA1 has previously been shown to have a defensive role in *M.*

193 *pneumoniae* and *K. pneumoniae* infection, enhancing bacterial clearance and

194 inhibiting biofilm formation [15, 16]. Here we show for the first time, that BPIFA1 also

195 has a major role in the defense against IAV. Notably higher weight loss was

196 observed and higher viral titers (> 1 $\log_{10}$) were recovered from the lungs of *Bpifa1*[-/-]

197 mice as compared to *wt* controls. A more rapid spread of IAV to the lung

198 parenchyma was also seen in *Bpifa1*[-/-] mice. Specifically, IAV antigen was observed

199 in the bronchiolar epithelium and alveoli of *Bpifa1*[-/-] but not of *wt* mice at 24 h p.i.

200 indicating a possible role for BPIFA1 both in intrinsic or innate defense during early

201 infection and in the adaptive immune response to IAV. The higher viral titers in lungs

202 after conditional knockdown of BPIFA1 in *Scgb1a1*-expressing club cells indicates

203 that the observations seen in the *Bpifa1*[-/-] mice are not due to developmental

204 adaptations to the total loss of BPIFA1 expression.

205   To investigate intrinsic functions of BPIFA1 in the airway epithelium we

206 cultured mTEC cells from *wt* and *Bpifa1*[-/-] mice. Although we did not formally rescue

207 the *Bpifa1*[-/-] cells using exogenous protein, we controlled for differences between

11

208   cultures by performing extensive phenotypic characterization. Thus, approximately

209   25% of the cells in *wt* mTEC had α2,3-linked sialic acid (SA) residues on the surface.

210   These cells were BPIFA1-negative. A similar proportion of cells (22%) were α2,3 SA-

211   positive in the *Bpifa1[-/-]* cultures. Very few cells on *wt* and *Bpifa1[-/-]* cultures were α2,6

212   SA-positive (3% and 5% respectively). Mouse-adapted IAV strains such as those

213   used in this study (X-31 and PR8) will use both α2,3- and α2,6-linked and sialic acid

214   residues as a receptor [32, 33]. The similar proportions of cells with α2,3- and α2,6-

215   linked and sialic acid residues between *wt* and *Bpifa1[-/-]* cultures indicates that

216   differences in infection and binding between *wt* and *Bpifa1[-/-]* are due to the absence

217   or presence of BPIFA1 and not differences in the number of cells expressing

218   receptors. Infection of mTEC cultures with IAV paralleled our observations *in vivo* in

219   that there was a significantly more rapid spread and higher viral titers in cultures

220   lacking BPIFA1. In line with the distribution of α2,3-linked sialic acid receptors, IAV

221   had a preference for infecting the BPIFA1-negative population. This confirms a role

222   for BPIFA1 in the intrinsic defense against IAV at the airway epithelium during the

223   first few days of infection and shows that the secreted protein exerts its effects on

224   the epithelial cell surface rather than solely in the cells that produce it.

225   Further analysis revealed a much greater import of IAV RNPs into the nuclei

226   of cells and significantly increased virus binding in the *Bpifa1[-/-]* cultures. The fact that

227   only a percentage of cells were infected in these assays reflects in part the complex

228   nature of mTEC ALI cultures and where only a proportion of the cells express the

229   α2,3- and α2,6-SA receptors. The greater level of inhibition in the RNP import assay

230   compared to the binding assay suggests an important role for BPIFA1 in decreasing

231   post-binding entry into cells via endosomes as well as initial binding of IAV to normal

232   ciliated epithelial cells in airways. BPIFA1 is secreted and is present in the periciliary

233 layer [34] so it is easy to envisage how it might be part of a barrier to IAV infection at

234 the epithelial surface. We did not characterize whether and how BPIFA1 binds to

235 virus particles. However, BPIFA1 could either form a non-specific barrier to IAV

236 engaging with cellular receptors, or bind to IAV and prevent receptor interactions.

237 Gel-forming mucins such as MUC5AC inhibit virus infection [35] and BPIFA1 has been

238 shown to associate with the mucus rich portion of the pericellular lining fluid [34, 36]. It

239 has been hypothesized that in the case of IAV this is due to competitive inhibition for

240 receptors as MUC5AC from mice contains abundant α2,3-linked sialic acid residues

241 [35]. The glycosylation on BPIFA1 contains sialic acid residues [37] and could potentially

242 act by binding to IAV particles via specific sialic acid-HA interactions. Alternatively,

243 BPIFA1 is a member of the wider tubular lipid-binding (TULIP) superfamily [38], has a

244 hydrophobic cavity and binds several lipids found in mammalian membranes [39]. It

245 therefore has the potential to bind to lipids found in the IAV membrane and interfere

246 with receptor binding and endosomal fusion. Further studies are required to

247 determine precisely how BPIFA1 blocks binding and entry of IAV into normal

248 epithelial cells.

249 Previous studies have shown that infection by a number of pathogens (e.g. *P.*

250 *aeruginosa*, *S. pneumoniae, M. pneumoniae,* murine γ-herpesvirus 68 and IAV)

251 cause an initial transient increase in secretion of the protein in the first 2 - 3 hours

252 post infection but this is followed by a decrease over 2 - 7 days [15, 18, 40]. Our results *in*

253 *vivo* extend these observations using IAV (Figs. 1 - 2). Decrease in BPIFA1 levels

254 after infection is mediated by pathogen-associated molecular patterns (PAMPs) and

255 IFN-γ [40]. The IAV strains used here target BPIFA1-negative ciliated epithelial cells

256 and BPIFA1 is produced by non-ciliated epithelial cells. Thus, although IAV induces

257 necrosis of respiratory epithelial cells, the decrease in BPIFA1 expression is unlikely

258   result from direct killing of BPIFA1-expressing cells. Also, intact respiratory epithelia

259   exhibited decreased BPIFA1 expression at day 7 p.i. (Fig. 2). IAV induces signaling

260   by a number of PAMPs and so the decrease in BPIFA1 could be due to this

261   mechanism [41]. Inactivated IAV had no effect suggesting that active replication is

262   required to mediate a decrease in BPIFA1 levels. After resolution of the initial

263   infection, BPIFA1 levels returned to pre-infection levels in BAL and the tracheal and

264   bronchial epithelium.

265   It seems unlikely that BPIFA1 has evolved to have a role in the defense

266   against IAV alone and thus it is likely that the protein will influence the pathogenesis

267   of other viruses. It has been shown to have an inhibitory effect on the replication of

268   Epstein-Barr virus (a membrane-bound herpesvirus) in lymphoblastoid cells [42].

269   Down-regulation of BPIFA1 expression [43] and polymorphisms in the BPIFA1 gene

270   are also associated with susceptibility to Epstein-Barr virus-associated

271   nasopharyngeal carcinoma [44]. It will be of interest to determine if BPIFA1 affects the

272   pathogenesis of other respiratory viruses.

273   These studies have uncovered a significant and unappreciated role for

274   BPIFA1 in host defense against experimental IAV infections in murine models. It

275   remains to be seen if this protein is able to modulate IAV infection in the human host

276   in a similar manner. The observation of elevated levels of BPIFA1 in nasal aspirates

277   of children with IAV [45] suggests that some modulation of the protein does occur

278   during clinical infection and thus is a potential biomarker. We propose that BPIFA1

279   may be one component of the airway surface lining fluid critical to antiviral host

280   defense. Further studies are needed to determine if natural variations in BPIFA1

281   levels due to genetic polymorphisms [44] may pre-dispose to more severe IAV-

282   associated disease.

283

284

Methods

Virus.

Influenza virus strains A/X-31 (X-31, H3N2) and A/PR/8/34 (PR8, H1N1) were propagated in the allantoic cavity of 9-day-old embryonated chicken eggs and titered by plaque assay on MDCK cells [46].

Mice.

Animal work was reviewed and approved by the local University of Liverpool Animal Welfare Committee and performed under UK Home Office Project Licences 40/2483 and 70/8599. Mice were all specified pathogen free and maintained under barrier conditions in individually ventilated cages. Transgenic *Bpifa1*[-/-] mice were bred at the University of Liverpool under UK Home Office Project Licence 70/8378. Transgenic mice deficient in BPIFA1 (*Bpifa1*[-/-]) and conditional knockout were generated (*Bpifa1*[loxP]; *Scgb1a1-CreER*[TM]) as described in S1 text and S1 Fig. Both transgenic strains were backcrossed 10 generations to C57BL/6J. Wild-type sex and age-matched C57BL/6J control mice were purchased from Charles River (UK).

Tamoxifen Administration.

A 20 mg/ml Tamoxifen (tmx) stock solution was dissolved in Mazola corn oil. Tmx was administered by gavage of 0.25 mg per gram body weight to *Bpifa1*[loxP]; *Scgb1a1-CreER*[TM] adults daily for five days. Mice were then infected with IAV 4 days after the last gavage.

Virus infection of mice.

Animals were randomly assigned into multiple cohorts, anesthetized lightly with KETASET i.m. and inoculated intra-nasally with 10^3 pfu IAV in 50 µl sterile PBS, or were mock-infected with a similar volume of allantoic fluid. Mice were sacrificed at

16

309   variable time-points after infection by cervical dislocation. Tissues were removed

310   immediately for downstream processing.

311   **Histology, Immunohistology.**

312   Histology and immunohistology (IH) was performed on paraformaldehyde-fixed,

313   paraffin-embedded tissue using the peroxidase anti-peroxidase (PAP) method as

314   previously described [47, 48]. Primary antibodies used were rabbit anti-mBPIFA1 [6] and

315   goat anti-IAV (Meridian Life Sciences Inc., B65141G).

316   **Quantitative Histopathological Assessment.**

317   The percentage area and density of DAB staining within airway epithelium was

318   quantified using whole slide images scanned and analyzed using Image-Pro Premier

319   image analysis software version 9.1 (MediaCybernetics Inc.). An automated macro

320   and app (named Trachea.ipp and Airways.ipx, respectively) were developed in

321   conjunction with MediaCybernetics Inc. They were designed to identify and outline

322   regions of interest comprising the airway epithelium of the trachea, bronchi and

323   bronchioles, while excluding other cells. The macro and app analyze thresholds of

324   hue, luminosity and saturation, which were set relative to the chromogen (DAB)

325   utilized for BPIFA1 localization. These data provided an average density of staining

326   for each region of interest. The percentage area stained was defined as the brown

327   area (positive immunostaining) divided by the total brown area plus blue area

328   (hematoxylin; negative staining) ×100.

329   **Western Blotting.**

330   Samples were analysed by 12.5% SDS-PAGE gel electrophoresis and blotted using

331   rabbit anti-mBPIFA1 [6]. Band density was measured using the gel analysis tool of

332   Image J software.

333   **Quantitative protein analysis.**

334 The Wes™ system was used to identify and quantify BPIFA1 protein in BAL and

335 lung samples (ProteinSimple) and rabbit anti-mBPIFA1 as primary antibody. The

336 area of BPIFA1 peak, in relation to the standard curve, was determined and virtual

337 blot-like images generated using Compass software (ProteinSimple).

338 **Mouse tracheal epithelial cell cultures.**

339 Mouse tracheal epithelial cells (mTEC) were isolated and differentiated into upper

340 airway-like epithelium in an air-liquid interface (ALI) culture following previously

341 described methodology with slight modification [28, 29]. Whole tracheas were excised

342 from 6-8 weeks old mice. Five or six tracheas were pooled for each evaluation.

343 **Immunofluorescent labeling and confocal imaging.**

344 Transwell membranes were fixed with 10% buffered formalin and then stained using

345 primary and secondary antibodies. Primary antibodies used were as follows: rabbit

346 anti-BPIFA1 (1:200)[6], rabbit anti-LPLUNC1 (1:100)[6], mouse anti-β tubulin (1:100;

347 Sigma Aldrich, Cat No- T5201), mouse anti-Foxj1 (1:100; eBioscience, Cat No- 14-

348 9965-82, Clone- 2A5), goat anti-SCGB1A1 (1:500; Gift from Barry Stripp), rabbit

349 anti-MUC5B (1:100; Santa Cruz; H-300, Cat no- sc-20119,) and mouse anti-

350 Influenza A virus NP (anti-IAV NP; 1:200; H16-L10-4R5 (ATCC® HB-65™)).

351 Secondary antibodies are as follows (all from Life Technology; 1:200): Alexa Fluor

352 568 Goat anti-rabbit antibody (Cat No- A11011), Alexa Fluor 488 Goat anti-mouse

353 antibody (Cat No- A11001), Alexa Fluor 488 Rabbit anti-goat antibody (Cat No-

354 A11078), Alexa Fluor 633 Goat anti-mouse IgG (Cat No- A21050). Samples were

355 mounted on glass slides with DAPI Vectashield (Vector Laboratories, Cat No- H-

356 1200) and visualized with an Olympus Fluoview 1000 Confocal microscope.

357 **Virus labeling and IAV binding assay.**

358 IAV A/PR/8/34 was purified from the allantoic fluid of infected eggs by pelleting

359 through a 30% sucrose/PBS cushion followed by banding on 15-60% sucrose/PBS

360 density gradients. Virus was then labelled using a green Alexa-fluorophore labelling

361 kit (Life Technologies) to yield Alexa Fluor 488-labelled virus (IAV-488). Unreacted

362 dye was removed by pelleting the virus at 125,000 g. For binding assays, IAV-488

363 was added to the apical surfaces of day 14 mTEC ALI cultures. After incubation for 1

364 h and washing off unbound virus, membranes were immediately fixed with 10%

365 buffered formalin and co-stained with anti-BPIFA1 and anti-FoxJ1 antibodies.

366 Images were captured from at least five fields per sample by confocal microscope.

367 Integrated fluorescence intensity was measured by Image J to assess the levels of

368 IAV-488 binding on the cell surface of mTEC cultures. Three independent

369 experiments were conducted with cells from three different batches of mice.

370 **Nuclear import assay of IAV ribonucleoprotein (vRNP) complexes.**

371 Apical surfaces of Day 14 ALI mTEC cultures were infected with purified IAV

372 A/PR/8/34. Following infection, cells were overlaid with DMEM/F-12 media

373 plus/minus cycloheximide (CHX) at a final concentration of 100 µg/ml (no CHX was

374 the control). Cells were incubated in 5% CO_2 at 37°C for 4 h, then washed three

375 times with pre-warmed HBSS and fixed with 10% buffered formalin as above.

376 Samples were processed and dual immunostained with anti-IAV NP as described

377 above. Cells displaying nuclear localization of viral RNP were counted at 40x

378 magnification in five fields (one center and four peripheral fields) per sample and

379 presented as a percentage of positive cells over total cells counted. Three

380 independent experiments were conducted with cells from three biologically different

381 batches   of   mice.

Author contributions

CDB, LB, AK, RAT; planned the project, designed experiments and analyzed the data. JPS. planned the project, designed experiments, analyzed the data, interpreted results, and wrote the manuscript. RVS planned and designed the transgenic knockout strategies. KMA designed and performed the *in vitro* mTEC experiments, analysed data and interpreted the results. NAM designed and performed the *in vivo* experiments, analysed data and interpreted the results. AS generated the *Bpifa1*^{loxP} and *Bpifa1*$^{-/-}$ transgenic mouse lines. SJ and SH helped perform the RNP import and binding assays. PD designed and interpreted the SNP import and binding assays. GHL performed and interpreted the histology and immunohistology examinations. All authors reviewed, revised, and approved the manuscript for submission.

Figure Legends

Figure 1. BPIFA1 protein levels in BAL are modulated after IAV infection. BAL samples were taken from C57BL/6J mice infected with IAV X-31 at multiple days p.i. The Simple Western (Wes™; ProteinSimple) system was used to quantify BPIFA1 protein using a rabbit anti-mBPIFA1 primary antibody. Equal amounts of protein (120 μg as determined by BCA, Pierce) were loaded per lane. The area of the BPIFA1 peak, in relation to the standard curve, was determined using Compass software (ProteinSimple). Bars represent mean ± SEM (n = 4). Statistically significant differences (One-way ANOVA with Tukey's post-hoc analysis) between groups are represented by square brackets above. * represents p <0.05; ** represents p < 0.01.

Figure 2. BPIFA1 level in airway epithelia is modulated after IAV infection. Lungs were dissected from C57BL6/J mice that were either mock- or IAV-infected (i.n. with 10^3 pfu IAV X-31) at multiple days p.i. as indicated. BPIFA1 was detected by IH using rabbit anti-mBPIFA1, visualized with DAB and counter-stained with hematoxylin. The percentage area of epithelium stained (left graph panels) and intensity of staining (right graph panels) in the trachea (**A**), bronchi (**B**) and bronchioles (**C**) were assessed by image analysis. Data are for four mice per group presented as mean ± SEM. Statistically significant differences (One-way ANOVA with Tukey's post-hoc analysis) between groups are represented by square brackets above. * represents p <0.05, ** represents p < 0.01, *** represents p < 0.001. Micrographs of representative areas at each time point are shown below the graph panels. Black arrows point to expression of BPIFA1 in respiratory epithelium. Scale bars represent; panel A: 50 μm, panel B: 10 μm and panel C:20 μm.

Figure 3. BPIFA1 influences the infection of mice by IAV. Panels A, B. C57BL/6J and *Bpifa1$^{-/-}$* mice (n = 4 per group) were infected i.n. with 10^3 pfu IAV X-31. **Panel A**. Mice were weighed daily and the weights represented as a percentage of the starting weight. Data represent the mean value ± SEM. Asterisks indicate statistical difference (two-way ANOVA with Bonferroni post-test; **represents $p <$ 0.01. **Panel B.** Lung tissues were taken at multiple days p.i. as indicated and virus titer determined by plaque assay. Data represent the mean value ± SEM. Asterisks indicate statistical difference (two-way ANOVA with Bonferroni post-test; * represents $p <$ 0.05, *** represents $p <$ 0.001). **Panel C**. Bpifa1^{loxP}; Scgb1a1-CreER^{TM} mice were treated with either carrier (vegetable oil) or carrier plus Tamoxifen (tmx) by oral gavage five times as described in materials and methods. Lung tissue (n = 4 per group) was analyzed by western blotting for BPIFA1. Equal amounts (100 μg) of protein as determined by BCA (Pierce) were loaded per lane. The mean (± SEM) levels of BPIFA1 protein were measured by Image J as integrated band intensity. * represents statistical significance (Mann-Whitney *U* test; $p <$ 0.05) BPIFA1 is clearly knocked down in the Tamoxifen-treated animals. **Panel D**. Tamoxifen-inducible, club cell specific BPIFA1 knockout mice (*Bpifa1^{loxP}; Scgb1a1-CreER^{TM}*) were dosed on 5 consecutive days by gavage with 0.25 mg per gram body weight tamoxifen (tmx) or carrier (vegetable oil). Four days after the last gavage these mice, along with untreated *Bpifa1^{loxP}; Scgb1a1-CreER^{TM}* and *Bpifa1$^{-/-}$* mice (n = 4 for all groups) were infected with IAV for 7 days. Lungs were collected and virus titer determined by plaque assay. Data represent the mean value ± SEM. Asterisks indicate statistical difference (One-way ANOVA with Tukey's post-hoc analysis; $p <$ 0.05).

Figure 4. IAV spreads more rapidly in the absence of BPIFA1. C57BL/6J and *Bpifa1^-/-^* mice were infected i.n. with 10^3 pfu IAV X-31. Lung tissues were harvested at one day p.i. IAV antigen was detected by IH using goat anti-IAV, visualized with DAB and counter-stained with hematoxylin. Micrographs of representative areas from distal bronchioles and alveoli four mice are shown. Large arrows, positive epithelial cells. Red arrowheads, positive macrophages.

Figure 5. BPIFA1 influences the infection of normal mTEC by IAV. mTEC ALI cultures were infected with IAV X-31 (0.1 pfu/cell). Panels **A – F**. Cells were processed and stained with anti-IAV NP (green), anti-mBPIFA1 (red), nuclei counterstained with DAPI (blue) and imaged using a confocal microscope. Scale bar represents 50 µm. Micrographs show representative areas from C57BL/6J mTEC cultures **(A, B, C)** and *Bpifa1^-/-^* mTEC cultures **(D, E, F)** at 2, 24 and 48 h p.i. **(G)** Mean integrated florescence intensity IAV nucleoprotein in mTEC ALI shown for 3 independent biological replicates (± SEM). * represents $p < 0.05$, One-way ANOVA with Tukey's post-hoc analysis. **(H)** Titer of IAV in apical wash. Data presented as mean ± SEM; n = 3; * represents $p < 0.05$, One-way ANOVA with Tukey's post-hoc analysis.

Figure 6. BPIFA1 decreases the nuclear import of IAV RNPs into normal mTEC. mTEC ALI cultures from *wt* C57BL/6J or *Bpifa1^-/-^* mice were incubated with purified IAV A/PR/8/34 in the presence or absence of cycloheximide (CHX) as indicated. Cycloheximide blocks protein synthesis and so indicates the import of pre-existing IAV RNP from incoming virus particles. After 4 h incubation at 37°C cultures were processed and stained with anti-IAV NP and counter-stained with DAPI before

visualization using a confocal microscope. Scale bar represents 50 µm. (**A**) Representative micrographs from cultures incubated with IAV in the absence or presence of CHX (**B**) micrographs from cultures incubated with IAV in presence of CHX at a higher magnification. (**C**) Nuclei that were positive for IAV NP in the presence of cycloheximide were counted at 40x magnification in five fields (one center and four peripheral fields) per sample and presented as a percentage of positive cells over total cells counted. The mean percentage positive nuclei are shown for 3 independent biological replicates (± SEM). * represents statistical significance (One-way ANOVA with Tukey's post-hoc analysis; $p < 0.05$)

Figure 7. BPIFA1 restricts binding of IAV to normal epithelial cells in mTEC ALI cultures. mTEC ALI cultures were incubated for 1 h with IAV Alexa-fluor 488-labeled purified IAV A/PR/8/34 (IAV-488), then fixed with formalin, stained with anti-BPIFA1 and anti-FoxJ1 antibodies and then imaged using a confocal microscope (**A**) Representative images of two different fields of day 14 C57BL/6J mTEC ALI culture showing IAV-488 (green) preferentially binding to FoxJ1-positive (white) ciliated cells but not BPIFA1 (red)-positive cell populations (circled by yellow dotted line). (**B**) Micrograph showing IAV-488 binding (green) with the epithelium of *wt* C57BL/6 and *Bpifa1*[-/-] cultures. (**C**) Integrated florescence intensity of IAV-488 virus binding with the surfaces of mTEC culture. Images were captured from at least five fields per sample by confocal microscope at 20x, 40x and 60x magnification. The levels of IAV-488 binding on mTEC cell surfaces were measured by Image J as integrated fluorescence intensity. The mean fluorescent intensity is shown for 3 independent biological replicates (± SEM). * represents statistical significance (Mann-Whitney *U* test; $p < 0.05$)

Results

Generation of transgenic mice deficient in BPIFA1.

Animal procedures for generation of the *Bpifa1*^{loxP} and *Bpifa1*^{-/-} transgenic lines were approved by the Institutional Animal Care and Use Committee at University of Hawaii under protocols 07-056 and 11-1112.

A conditional targeting vector for *Bpifa1* used for transfection of C57BL/6J mouse embryonic stem cells was constructed by InGenious Targeting Laboratory, Inc. (Ronkonkoma, NY). The targeted region on the *Bpifa1* gene includes exons 2-3 (see S1 Fig. A).

Embryonic stem cells were microinjected into BALB/c blastocysts. Resulting chimeras with a high percentage black coat color were mated to wild-type C57BL/6J mice to generate F1 heterozygous offspring. Correctly targeted F1 mice contained a Neo-selection cassette, three lox-P sites and two FRT sites.

Deletion of the Neo-cassette was achieved by breeding with a heterozygous C57BL/6J background FLP^{+/-} mouse (Jackson Laboratories, JAX; stock# 003800). Since these FLP mice are heterozygotes (homozygotes are embryonic lethal), the resulting F2 mosaic mice were screened for presence of the FLP transgene and deletion of the Neo cassette. After breeding with C56BL/6J mice, the resulting F3 generation was screened for FLP transgene absence and deletion of the Neo cassette. This mouse was bred with another heterozygous FLP^{-/-} and Neo^{-/-} F3 offspring to produce a homozygous floxed F4 mouse without the FLP transgene and without the Neo cassette (*Bpifa1*^{loxP}).

To generate a systemic *Bpifa1* KO mouse *(Bpifa1*^{-/-}*)*, *Bpifa1*^{loxP} mice were mated with a mouse containing the Cre-recombinase transgene under the control of

hCMV IE promoter (CMV-Cre, formally B6.C-Tg(Tg (CMV-Cre)1Cgn/J; JAX Stock No: 006054; see S1 Fig. A).

Bpifa1^{loxP} and Bpifa1$^{-/-}$ mice were deposited at the MRC Mammalian Genetics Unit (Harwell, UK; FESA:5217 and 5945 respectively) and then transferred from there to the University of Liverpool.

To generate a conditional, club cell-specific KO mouse (Bpifa1^{loxP}; Scgb1a1-CreER^{TM}), Bpifa1^{loxP} mice were mated with Scgb1a1-CreER^{TM} (Scgb1a1$^{tm1(cre/ERT)Blh}$; Jackson Lab, stock# 016225) [1]. These mice express a tamoxifen-inducible form of cre recombinase from the Scgb1a1 locus (secretoglobin).

Phenotyping of Bpifa1$^{-/-}$ mice.

Four wild type (wt) mice (C57BL/6J) and four Bpifa1$^{-/-}$ mice, two males and two females of each, aged 6 – 10 weeks, were examined grossly and histologically for phenotypical differences as a result of lack of expression of the Bpifa1 gene. There were no differences grossly. Histological examination of the lymphoid, gastrointestinal, urinary, cardiovascular, endocrine, reproductive organs and the CNS was unremarkable. In addition to the respiratory tract, BPIFA1 is expressed in minor glands of the nose, sinuses, posterior tongue and tonsil [2, 3], in some of the seromucous cells of the major salivary glands and is detectable in saliva. In glandular tissues examined (submandibular, parotid and sub-lingual salivary glands, minor tongue (von Ebner's) gland, Zymbal's gland, Harderian gland and lacrimal gland), the only difference noted was that the eosinophilic granules within the epithelium of the convoluted tubules of the submandibular salivary glands, which are prominent in male mice only, were far less striking in the male Bpifa1$^{-/-}$ mice. The serous and mucous

glands were unaffected, and Alcian blue (AB) and periodic acid-Schiff (PAS) staining yielded similar results in both *wt* and *Bpifa1*[-/-] mice in these glands (data not shown).

The tissues of the upper and lower respiratory tract were examined using H&E, AB and PAS stains, as well as immunohistology (IH) for BPIFA1 and SCGB1A1. Tissues from *Bpifa1*[-/-] were consistently IH-negative for BPIFA1, and there were no differences in the intensity or distribution of SCGB1A1 immunostaining between the *wt* and the *Bpifa1*[-/-] mice. In *Bpifa1*[-/-] mice the nasal respiratory epithelial cells at the transition to the olfactory epithelium generally exhibited abundant hyalinized globular cytoplasmic material, leading to expansion of the cells (S1 Fig C). This is a common finding in many strains of mice and increases in severity with age [4-6] but is of interest as in the present study it was only present in the *Bpifa1*[-/-] mice, and at this young age. In the trachea, bronchi and lower respiratory tract, no phenotypical differences were noted between the wild type and *Bpifa1*[-/-] mice.

Normal tracheal epithelial cultures (mTEC) are a good model to study IAV infection in vitro.

Normal mouse tracheal cell cultures were established from C57BL/6J mice and cultured at the air-liquid interface to generate well-differentiated cultures (mTEC). Differentiated mTEC ALI cultures displayed phenotypic features associated with a complex population of ciliated cells (β-tubulin), BPIFA1, mucin (MUC5B), Foxj1 (cilia marker) and SCGB1A1 (CCSP)-expressing cells that matched with the features of the native rodent airway epithelium (S3 Fig. A, C, D, E). The surface topology of day 14-differentiated mTEC ALI cultures also showed ciliated epithelial cells interspersed with domed shaped non-ciliated cells with a cobble stone appearance, which is typical of the upper airway morphology (S3 Fig. B). The expression of a selected cohort of

airway epithelium-specific genes was also assessed in 14-day cultures to further validate our *in vitro* model. SCGB1A1 (a club cell marker), and BPIFB1 (LPLUNC1) gene expression was present but relatively low when compared with mTEC original cells (freshly isolated mTEC cells without culture modification) (S3 Fig. F). BPIFA1 was readily detected in cultured epithelial cells and within the apical secretions (S3 Fig. A, G) but was not found in ciliated cells (S3 Fig. A, C). Airway epithelium-associated genes, *Bpifa1*, *Bpifb1, Scgb1a1, Muc5ac*, *Muc5b*, *Tekt-1* (a cilia gene) were consistently expressed in Day-14 mTEC ALI cultures and matched with the original cell gene expression signature of the mTECs (S3 Fig. F). The *in vitro* tracheal cultures are thus a good *in vitro* model with which to study BPIFA1 biology during IAV infection.

Supplementary Figure Legends

S1 Fig. Construction and characterisation of *Bpifa1^{loxP}* and *Bpifa1^{-/-}* mice

Panel A (i). Wild-type *Bpifa1* locus. The targeted region on the *Bpifa1* gene includes exons 2-3. **(ii).** Targeting vector. The conditional targeting vector contained exons 2 and 3 flanked by LoxP sites and a Neo selection cassette flanked by FRT sites. **(iii).** Deletion of the Neo-cassette was achieved by breeding with a heterozygous C57BL/6J background FLP^{+/-} mouse to generate conditional targeted *Bpifa1^{loxP}* mice. **(iv).** To generate a systemic *Bpifa1* KO mouse *(Bpifa1^{-/-})*, *Bpifa1^{loxP}* mice were mated with a

mouse containing the Cre-recombinase transgene under the control of hCMV IE promoter.

Panel B. Western blot analysis of lung tissue from either wild-type C57BL/6J or *Bpifa1*$^{-/-}$ mice (as indicated) using rabbit anti-BPIFA1 as primary antibody. The first lane shows the molecular weight markers. A characteristic 27-31 kDa doublet was observed corresponding to alternatively-glycosylated forms of BPIFA1 in the wild-type but not *Bpifa1*$^{-/-}$ mice.

Panel C. Nasal cavities of C57BL/6J and *Bpifa1*$^{-/-}$ mice were dissected, processed for histology and stained with hematoxylin/eosin. In *Bpifa1*$^{-/-}$ mice there was hyalinised globular cytoplasmic material present in the respiratory epithelium at the transition to olfactory epithelium shown by black arrows. Micrographs of representative areas from four mice are shown.

S2 Fig. IAV-specific staining in mice at 1 day p.i. C57BL/6J and *Bpifa1*$^{-/-}$ mice were infected i.n. with IAV X-31. Lung tissues were taken at one day p.i. IAV antigen was detected by IH using goat anti-IAV, visualized with DAB and counter-stained with hematoxylin. Micrographs of representative areas from four mice are shown. Large arrows, positive epithelial cells.

S3 Fig. Validation normal tracheal epithelial cell (mTEC) model. Tracheal epithelial cells were prepared from C57BL/6J mice and differentiated at the air-liquid interface for 14 days. (**A**) Confocal image showing cells stained for β-tubulin (ciliated cells; green) and BPIFA1 (red). The Z-slice (side panels) shows BPIFA1 cells are non-ciliated. (**B**) Scanning electron micrograph of the apical surface of the mTEC cultures showing ciliated cells and non-cilated cells with a cobble-stone appearance. (**C, D, E**)

Confocal images showing BPIFA1 and FoxJ1 (**C**), MUC5B (**D**) and SCGB1A1 (**E**) in day 14 ALI cultures of WT mTECs. (**F**) RT-PCR showing airway epithelium associated gene expression profile of mTEC ALI culture of WT (representative of three independent cultures). The OAZ-1 gene was used as housekeeping gene [7] (**G**) Western blot on apical washes collected from WT mTEC-ALI culture (representative of three independent cultures). Scale bar for confocal images represents 50 µm.

S4 Fig. Validation of the phenotype of mTEC ALI cultures from *Bpifa1^{-/-}* mice. mTEC ALI cultures from wild-type C57BL6/J and *Bpifa1^{-/-}* mice were analyzed by confocal microscopy. Micrographs show representative areas from three separate cultrues. Panels **A, B**. Cells were processed and stained with anti-β-tubulin (cilia marker; green), anti-mBPIFA1 (red) and nuclei counterstained with DAPI (blue). Panels **(C, D)** Cells were processed and stained with anti-MUC5B (mucin secreting cells; red) and nuclei counterstained with DAPI (blue). Scale bar represents 50 µm.

S5 Fig. Detection of α2,3- and α2,6-linked sialic acid residues on uninfected mTEC. The presence of α2,3-linked sialic acid (SA) and α2,6-linked SA residues on the surface of cells was detected by binding of fluorescein-labelled lectins from *Maackia amurensis* (MAA) and *Sambucus nigra* (SNA), respectively. Uninfected day 14 ALI cultured mTECs were dual-labelled with either anti-BPIFA1 plus MAA or anti-BPIFA1 plus SNA. (**A**) α2,3-linked SA receptor expression (detected by MAA) was present in both *wt* and *Bpifa1^{-/-}* mTEC cultures. Interestingly, the BPIFA1⁺ cell population was absolutely devoid of α2,3-linked SA residue expression. (**B**) α2,6-linked SA receptor expression (detected by SNA) was only seen in a low proportion of

cells in both *wt* and *Bpifa1*$^{-/-}$ mTECs. (**C, D, E**) Occasional expression of α2,6-linked SA residues was detected in BPIFA1$^+$ mTECs. This is a representative result from three separate experiments on two batches of mice. Scale bar represents 20 μm.
