ABSTRACT

Low-powered devices are ubiquitous in this modern age especially their application in the urban and built environment. The myriad of low-energy applications extend from wireless sensors, data loggers, transmitters and other small-scale electronics. These devices which operate in the microWatt to milliWatt power range and will play a significant role in the future of smart cities providing power for extended operation with little or no battery dependence. Low energy harvesters such as the aero-elastic belt are suitable for integration with wireless sensors and other small-scale electronic devices and therefore there is a need for studying its optimal installation conditions. In this work, a case study presenting the Computational Fluid Dynamics modelling of a building integrated with aero-elastic belts (electromagnetic transduction type) was presented. The simulation used a gable-roof type building model with a 27° pitch obtained from the literature. The atmospheric boundary layer flow was employed for the simulation of the incident wind. The work investigates the effect of various wind speeds and aero-elastic belt locations on the performance of the device giving insight on the potential for integration of the harvester into the built environment.

The apex of the roof of the building yielded the highest power output for the aero-elastic belt due to flow speed-up maximisation in this region. This location produced the largest power output under the 45° angle of approach, generating an estimated 62.4 milliWatts of power under accelerated wind in belt position of up to 6.2 m/s. For wind velocity of 10 m/s, wind in this position accelerated up to approximately 14.4 m/s which is a 37.5% speed-up at the particular height. This occurred for an oncoming wind 30° relative to the building facade. For velocity equal to 4.7 m/s under 0° wind direction, airflows in facade edges were the fastest at 5.4 m/s indicating a 15% speed-up along the edges of the building.

1. INTRODUCTION

The buildings sector demands 20 to 40% of total global power intake. This corresponds to values greater than the consumptions of industry and transport sectors [1]. Therefore new technologies that can mitigate or reduce the building energy demand are increasingly being developed; one of them is wind energy

44 technology. One major benefit of building-integrated wind energy harvesting is
45 bringing the power plant closer to the power consumers.

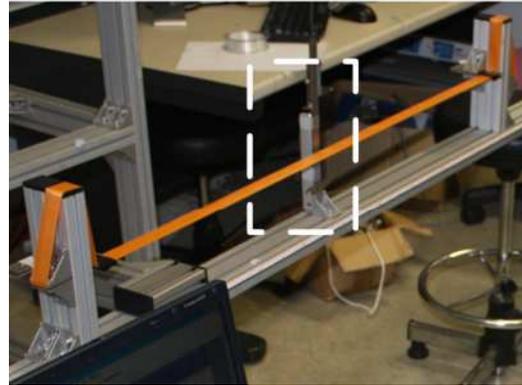

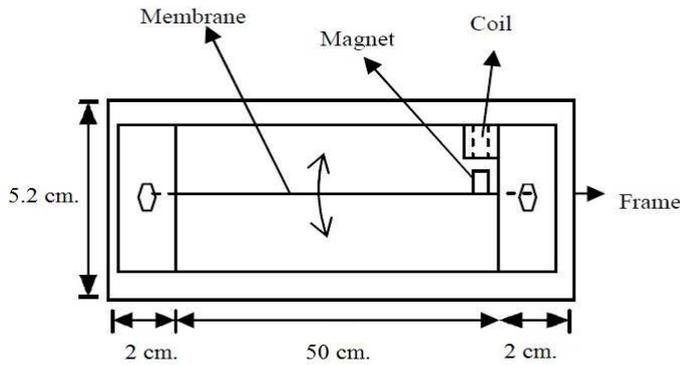

46
47 With the public having increased power creation capabilities, people can expect
48 higher energy efficiency and reduced dependence to energy companies, lower
49 carbon footprint and overall stimulation of the economy. Furthermore, it will decrease
50 the load of the grid, dependence on diesel generators (in events of power outage)
51 and more notably, lower transmission costs.

52
53 However, urban and suburban locations pose considerable problems for
54 conventional mounted turbines. First is the significant turbulence in these areas,
55 preventing the turbines from harnessing laminar wind flow. In these conditions wind
56 turbine installers face deficiency in analysing the more complex wind conditions. This
57 leads to the issues of unfavourable turbine site selection and therefore deficient
58 power production.

59
60 Extreme vibration and noise generated by conventional wind turbine operation also
61 present a great challenge in their integration into buildings. Another issue that
62 rotational turbines face is the hazard of having blades fly off. These factors contribute
63 to the anxiety of turbine installation among building owners and residents. But
64 possibly the biggest challenge to the building-integrated wind turbine (BIWT) is its
65 cost-effectiveness. Smaller wind turbines suitable for urban installations when
66 fastened onto buildings have a high cost-to-energy-production ratio.

67
68 An emerging and novel alternative to the conventional turbines are wind-induced
69 vibration energy harvesters. In recent years, low-energy power generation devices
70 have been receiving increased attention due to their potential integration with self-
71 powered micro-devices and wireless sensor networks in urban areas. Nano-
72 generators have a wide span of potential power applications ranging from
73 environmental and infrastructure monitoring, personal electronics to even wireless
74 biosensing [3]. The power produced by these nano-generators is adequate to run
75 light-emitting diodes [4], small liquid crystal displays [5] and self-powered wireless
76 sensor nodes [3].

77
78 Such devices like the aero-elastic belt as shown in Figure 1 can be in a form of a
79 small-scale wind generator that takes advantage of the flutter effect. Unlike turbine-
80 based generators, the aero-elastic belt is a small-scale, light and inexpensive direct-
81 conversion energy harvester which does not use any bearings, gears or rotors.

83

84
85 Fig 1. (a) Schematic diagram of an aero-elastic belt [6] (b) Example of experimental
86 aero-elastic belt setup [7]
87

88 The standard rotating wind turbines mostly are not as effective when transformed into
89 smaller types. However, flutter-based generators like the aero-elastic belt can
90 designed to fit lighter applications. It can operate in the range of microWatt to
91 milliWatt power generation. Although the power output is low, it has its advantages
92 compared to regular wind turbines. The aero-elastic belt is cost effective and can
93 also be made of simple household materials. The device is small, compact, modular
94 and suitable for turbulent flow, making it appropriate for integration with wireless
95 sensors – an area which has the biggest application potential for this technology [8].
96

97 Current global demand for wireless sensors is increasing especially in applications of
98 equipment supervision and monitoring revolving around energy expenditure, usage,
99 storage and remote manipulation especially in the following areas:

- 100 ● Medicine and health: prescription of patient-sensitive medications, remote
101 monitoring and vital signs alerts
- 102 ● Buildings: energy spending monitoring, security surveillance, structural health
103 monitoring, damage detection
- 104 ● Industry: systems tracking, data transfer, and equipment remote control
- 105 ● Infrastructure & environment: traffic monitoring, indoor air safety levels, air and
106 water pollution levels

107
108 These devices can be powered using low-energy generation technologies such as
109 flutter and vibration harvesters. Figure 2 illustrates the wide array of applications that
110 wireless sensors are operating in including, but not limited to, cities and urban
111 environments. The primary obstacles to what is referred to as the “deploy-and-forget”
112 quality of wireless sensor networks (WSN) are their limited power capacity and their
113 batteries’ unreliable lifespans. To overcome these issues, low-energy harvesting of
114 ambient energy resources like air flow, water flow, vibrations, and even radio waves
115 has become an encouraging new field. Along with advancements in microelectronics,
116 power requirements for wireless sensor nodes keep on dropping, ranging presently
117 from microWatts to a few milliWatts [8].
118

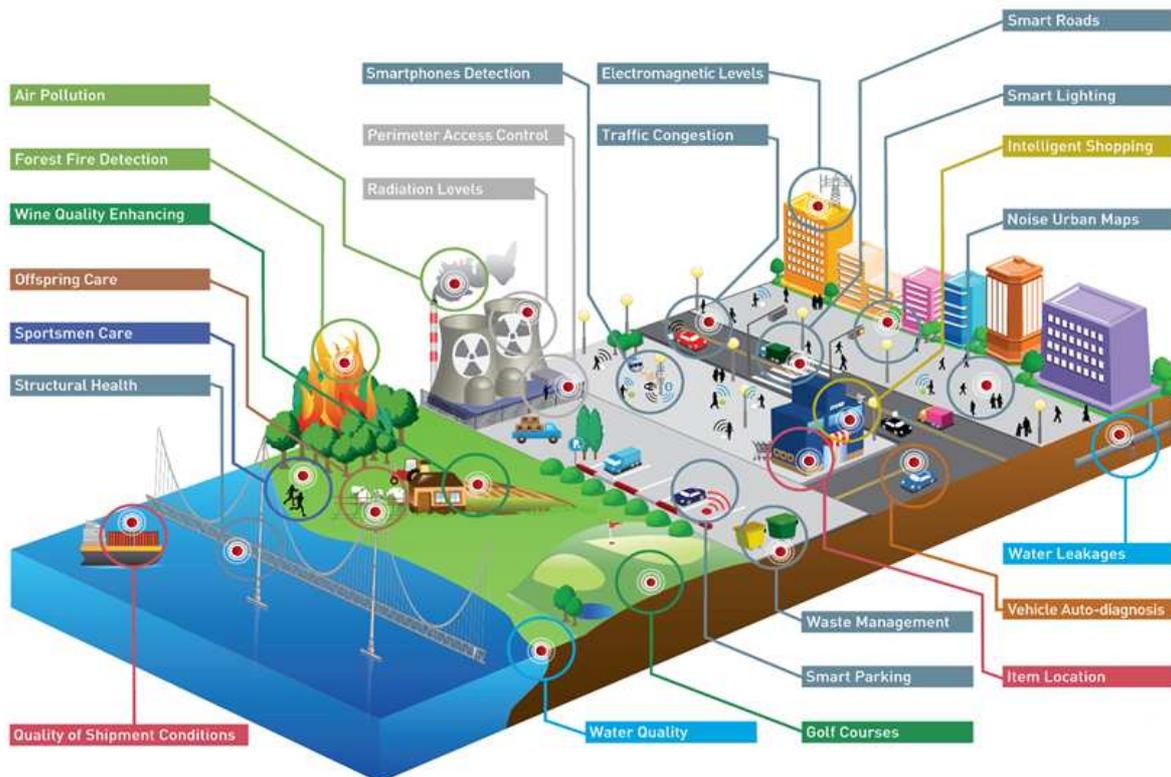

Fig. 2. Applications of wireless sensors in smart cities [9]

119
120
121

The global market for energy harvesting devices and modules is growing with a forecasted increase in value from \$19 Million in 2012 to \$227 Million in 2017 – a 12-times increase in five years, with an annual growth of 51% per annum. It is important to mention that within the range of applications of energy harvesting devices, the buildings sector makes up the biggest portion of the market.

127

In 2011, there were more than 1 Million harvester modules sold across the world for building applications alone. This is due to the large network of wireless switches for lighting, air conditioning and sensors detecting occupants' presence and measuring ambient room conditions such as humidity, all found in commercial buildings. Driving the market growth of energy harvesters are the large reduction in installation costs and maintenance-free operability requiring little or no wires [10]. Therefore, new methods should be developed to further assess and optimised its integration with the built environment.

136

In this paper, the current status of vibration energy harvesting technologies, their scopes, advantages and limitations will be discussed followed by case study focusing on the analysis of the integration of an aero-elastic flutter technology into buildings using Computational Fluid Dynamics (CFD) modelling.

2.1 Flow-induced vibrations

Aero-elastic flutter or simply referred to in this study as flutter, is a phenomenon of self-feeding oscillations upon which the aerodynamic forces on a structure associate with the inherent oscillation mode thereby producing fast recurring motion. Flutter can take place upon any body exposed to powerful steady fluid flow, under the precondition that a reinforcing feedback response ensues concerning the body's oscillation and the working fluid forces [8].

Flutter on itself can be severely catastrophic. Historic examples of flutter are the collapse of Tacoma Narrows Bridge and that of Brighton Chain Pier, as shown in Figure 3. The structures collapsed due to span failure caused by aero-elastic flutter [11]. Nevertheless, this seemingly violent nature of flutter can also be its source of strength when its potential for energy harnessing is explored.

Flow-induced vibrations (FIV) is an umbrella category that includes flutter-induced vibrations or what the study will refer to as aero-elastic flutter or simply flutter, and vortex-induced vibrations [8].

2.1.1 Extracted power and efficiency

For an incoming fluid flow, the energy that can be extracted is derived from the sum of two terms: the plunging term $P_Y(t)$ and the pitching term $P_\theta(t)$:

$$P_\theta(t) = P_Y(t) + P_\theta(t) = F_Y(t) V_Y(t) + M(t) \omega(t) \quad (1)$$

where F_Y is the component of the force in the y-direction while M is the resulting torque relative to the pitching centre.

Instantaneous power can be expressed in nondimensional form as:

$$C_P = \frac{P}{\frac{1}{2}\rho U_\infty^3 c} \quad (2)$$

When integrated over one cycle, this instantaneous C_P gives the time-averaged power coefficient over one cycle called C_{Pmean} , given by the expression:

$$C_{Pmean} = C_{Phmean} + C_{P\theta mean} = \frac{1}{TU_\infty} \int_0^T [C_Y(t)V_Y(t) + C_M(t)\omega(t)]dt \quad (3)$$

where T is the period of oscillation, $C_Y(t)$ is the instantaneous lift coefficient and $C_M(t)$ is the momentum coefficient. These quantities are given in terms of ρ , U_∞ and c :

$$C_Y(t) = F_Y(t) / \frac{1}{2}\rho U_\infty^2 c \quad (4)$$

$$C_M(t) = M(t) / \frac{1}{2}\rho U_\infty^2 c \quad (5)$$

The ratio of the average total power yield to the total power obtainable from the incoming airflow flowing across the swept region is defined as the power-extraction efficiency η :

$$\eta = \frac{P_{mean}}{\frac{1}{2}\rho U_\infty^3 A} = C_{Pmean} \frac{c}{A} \quad (6)$$

where A is the overall vertical distance of the movement of the aerofoil with both plunging and pitching motions being considered.

While it has been established that energy extracted from airflow originates from the sum of a plunging contribution C_{Ph} and a pitching contribution $C_{P\theta}$, for a foil with modified flapping motion the major source of extracted energy is through the plunging motion; the average extracted energy from the pitching motion is almost zero.

For a fixed pitching amplitude θ_0 , C_{Pmean} increases with the reduced frequency k at first, then C_{Pmean} eventually decreases with the further increase in k . For every value of θ_0 there exists an optimal k for the maximum C_{Pmean} .

Similarly, for a fixed reduced frequency k this time, the same behaviour for C_{Pmean} can be noticed with respect to varying θ_0 . Due to their effects to the angle of attack, k and θ_0 were observed to affect the development of leading edge vortices (LEV) as well as changes in the lift coefficient C_Y . It was also observed that high values for k

216 and low values for θ_0 lead to higher plunging velocity V_γ and better synchronization
217 between the lift coefficient and the plunging velocity compared to different scenarios.
218 Concerning the amount of energy extracted, this is the best case. Therefore, to
219 achieve the best performance for energy generation, relatively high k and low θ_0 are
220 preferred [12].

221

222 **2.2 Technologies**

223

224 In this sub-section, three types of vibration energy harvesting technologies are
225 reviewed; electromagnetic, piezoelectric and triboelectric devices.

226

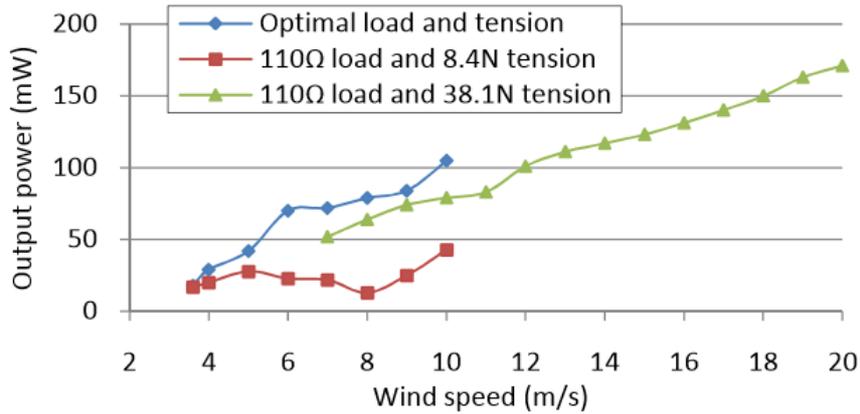

227 **2.2.1 Electromagnetic Vibration Devices**

228

229 An example of an electromagnetic vibration device is the aero-elastic belt or also
230 commonly known as the wind-belt, which is a small-scale wind generator that
231 operates based on the phenomenon of aero-elastic flutter. The original invention puts
232 the power production of wind-belts in the range from several milliWatts for the
233 smallest-scale device to a 7.2 kWh device which is 1 m long operating in 6 m/s winds
234 [13]. A significant upside is the production cost of such a low-power device could be
235 very small as well.

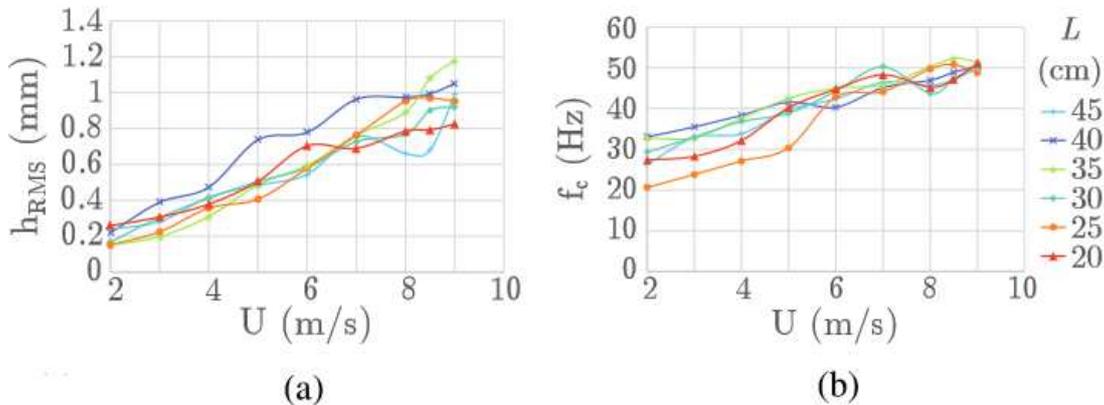

236

237 In the study of Pimentel et al. [14], a wind-belt prototype was characterised. The
238 device was 50-cm long and supported by a Plexiglass frame, with a tensioned Mylar
239 membrane installed with bolts on its ends. This membrane had one side that is
240 smooth and the other rough, thereby producing a simple aerofoil. The generator had
241 an electromagnetic transducer incorporated in one end of the membrane. This
242 transducer makes use of two small neodymium (NdFeB) magnets and a static coil
243 positioned adjacent to the magnets. The wind flowing around the tensioned
244 membrane caused it to flutter while the magnets vibrate relative to the coil, therefore
245 inducing a current flowing in the coil, producing electric power as shown in the results
246 in Figure 4. Based on the experimental results the minimum and maximum power
247 output were: 5 milliWatts for airflow velocity equal to 3.6 m/s and load resistance of
248 10 Ω and 171 mW at 20 m/s, 110 Ω resistance and 38.1 N membrane tension.

249
250 Fig. 4. Power output for the wind-belt experimental test setup in [14]
251

252 Numerous parameters that affects the wind belt harvester's performance like the
253 membrane tension, membrane length, magnet position and number of magnet were
254 investigated by Arroyo et al. [13] using experimental testing. The study highlighted
255 the optimal values for the key parameters, focusing on low wind speeds ranging from
256 1 to 10 m/s but with powerful vibration acceleration [13]. The experimental results
257 showing the amplitudes and frequencies for varying lengths of the ribbon used is
258 shown in Figure 5.

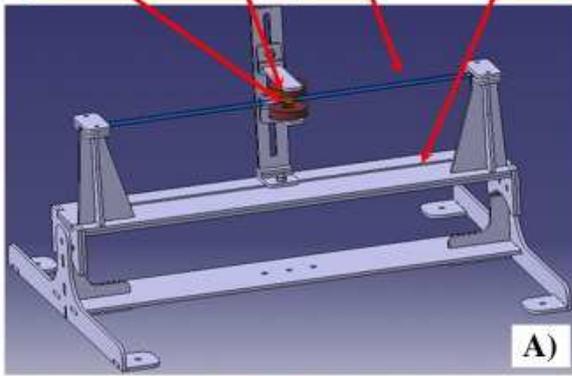

259
260 Fig. 5. (a) Amplitude and (b) Frequency of vibration as a function of wind speed for
261 various ribbon lengths [13]
262
263

264 Dinh Quy et al. [15] investigated a windbelt with the magnet mounted centrally along
265 the flexible membrane made of a type of kite fabric called ripstop nylon fabric as
266 shown in Figure 6. The single unit micro generator was able to produce power in the
267 range of 3 - 5 mW. Five larger versions of these micro generators were combined to
268 construct a windpanel, and together were able to generate 30 to 100 mW of power at
269 wind speeds of less than 8 m/s. At low wind speeds between 3 to 6 m/s, the output
270 current is approximately 0.2 to 0.5 mA, the generated voltage is between 2 to 2.5 V,

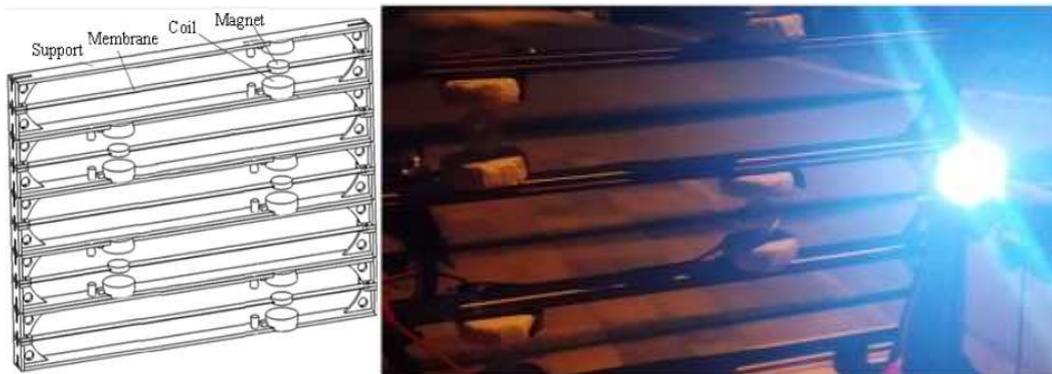

271 and the generated power is about 2 to 3 mW, under membrane oscillation frequency
272 of approximately 5 Hz.

(2) Magnet (1) Coil (3) Membrane (4) Support

273
274 Fig. 6. (a) 3D model of the wind belt design and (b) Fabricated test model studied in
275 [15]
276

277 In Dinh Quy et al. [15] five of the single membrane generators were merged to
278 fabricate a windpanel to increase the overall power output. The design of a single
279 generator in this study was made in such a way that grouping can easily be
280 constructed or dismantled. For each generator, two conducting coils of 4000 turns
281 each were used and placed parallel to each other as shown in Figure 7.

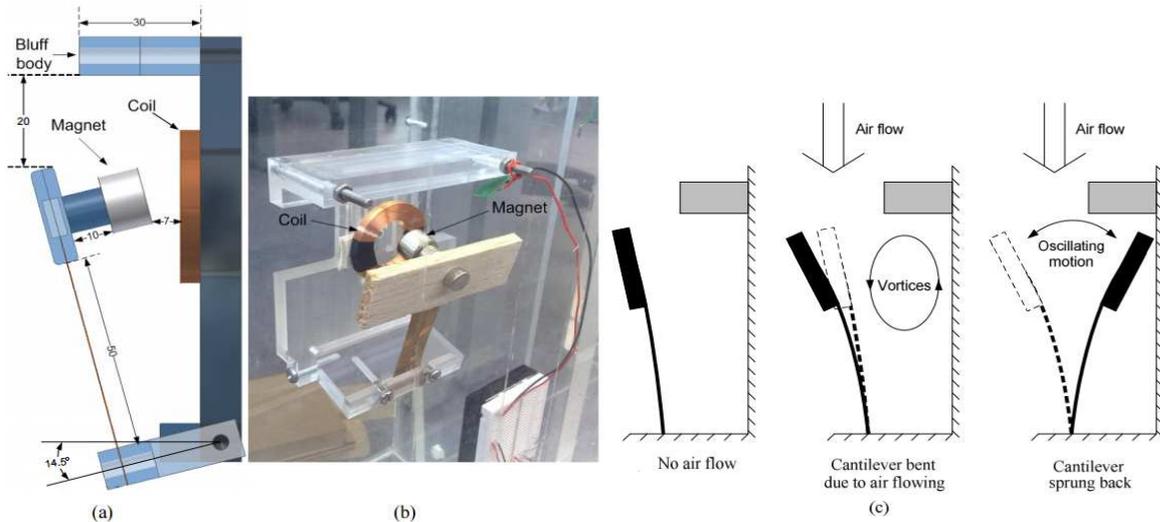

282
283 Fig. 7. (a) The 3D model of the windpanel - a combination of five windbelts (b)
284 Testing of the windpanel powering an LED light in actual wind conditions [15]
285

286 The earlier versions of flutter generators had practical problems as identified by Fei
287 et al. [16]. One instance would be the physical contact of the vibrating membrane
288 with the conductors once the membrane oscillation amplitude is greatest during
289 strong winds. The positioning of the magnets fastened on the membrane must be
290 carefully examined to guarantee optimised magnetic flux experienced by the
291 conductors, which was also addressed by Dinh Quy et al. [15]. To tackle these
292 problems and at the same time increase the efficiency of energy harvesting by a
293 fluttering membrane, a novel variety of flutter-based-harvester was proposed in [16]
294 which consists of a beam that acts as the support, an electromagnetic resonator, a
295 power management circuit, a supercapacitor for storage of charge [16] and a spring.

296 A thick polymer belt was used as the vibrating membrane having dimensions of 1 m
 297 by 25 mm by 0.2 mm. The electromagnetic resonator was positioned close to the end
 298 of the membrane. This was the preferred placement because of a higher bending
 299 stiffness of the membrane close to the secured ends. This configuration allowed a
 300 heavier magnet to be supported by the vibrating membrane [16]. The supercapacitor
 301 is easily replaceable.

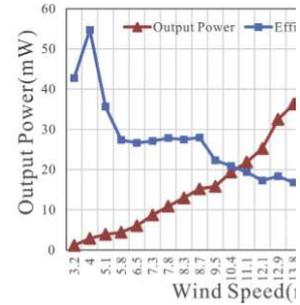

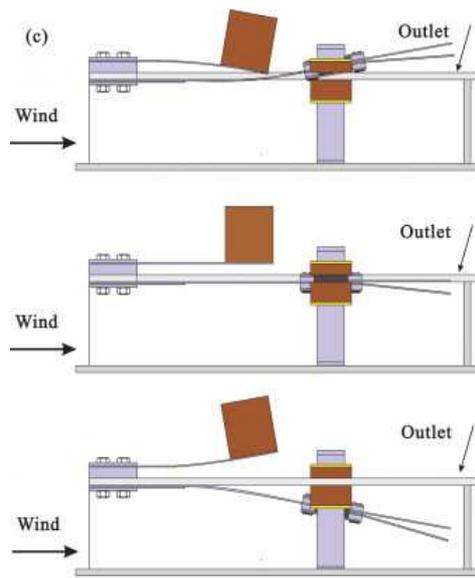

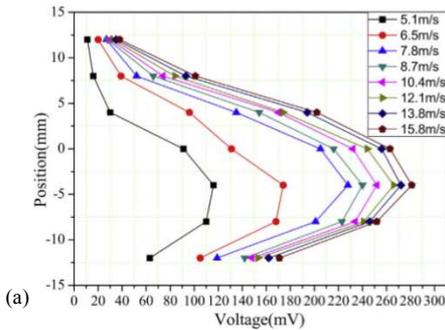

302
 303 Dibin Zhu et al. [17] investigated a device with an aerofoil connected to a beam which
 304 was positioned after a bluff body as illustrated in Figure 8. This harvesting device
 305 operated at a relatively low wind velocity of 2.5 m/s and generated power equal to
 306 470 microWatts. A disadvantage of this setup was requiring an initial displacement
 307 for the aerofoil in order to operate.

308
 309 Fig. 8. (a) Schematic of energy harvester studied in [17] with measurements in mm
 310 (b) Experimental setup of the harvester (c) Operating principle of the energy
 311 harvester
 312

313 Wang et al. [18] demonstrated a novel EMG-resonant-cavity wind generator
 314 integrated with dual-branch reed and tuning fork vibrator. The study highlighted the
 315 device's magnetic circuit being able to intensify the rate of change of the time-varying
 316 magnetic flux. The tuning-fork assembly of the device was able to further decrease
 317 system losses. Peak power output was observed to be 56 mW for airflow speed
 318 equal to 20.3 m/s with corresponding conversion efficiency of 2.3% at airflow speed
 319 of 4 m/s. The experiments provided evidence that the device can operate in a large
 320 range of wind speeds. The diagrams and working process of this wind energy
 321 harvester are shown in Figure 9.

position
 329 power
 330 of
 331 [18]

330 Kim et al. [19] investigated two
 331 electromagnetic energy harvesters
 332 utilise direct airflow power
 333 conversion to mechanical oscillations - (i) a wind-belt-like oscillatory linear energy
 334 harvester specifically for powerful air streams and (ii) a harvester centred on a
 335 *Helmholtz resonator* concentrated on sifting energy from weaker air current such as
 336 environmental air streams. The proposed wind-belt-like energy harvester was
 337 centred on the principle of aero-elastic flutter effect. It was composed of a polymer
 338 resonator together with entrenched magnets, a polymer casing and copper coils. The
 339 moving part of the generator was made up of an oscillating membrane with fastened
 340 permanent magnets, placed in the centre of the flow passage. The device casing had
 341 an inlet and an outlet for the airflow. The peak-to-peak open-circuit voltage for two
 342 types of belt materials, Mylar and Kapton, are shown in Figure 10 (a), while output
 343 voltage was measured for different airflow strengths shown in Figure 10 (b).

types of
 344 that

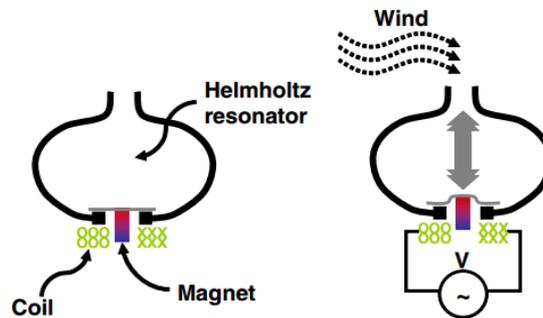

344 Fig. 10. (a) Measured peak-to-peak open-circuit voltage while varying input pressure
 345 (b) Output voltage in coil measured under weak and strong wind [19]
 346
 347

348 The second energy harvester made use of a Helmholtz resonator as a mechanism to
 349 concentrate oncoming wind flow. In simple terms, a Helmholtz resonator has a
 350 chamber filled with air, with an unconstrained neck, in which an ordinary fluid

351 oscillation takes place. Being a resonator, the air within the neck serves as the
352 oscillating weight while air within the air chamber serves as the elastic mechanism.
353 Figure 11 displays the operating principle for this energy harvester. This harvester is
354 claimed to be able to operate in extremely slow flows.

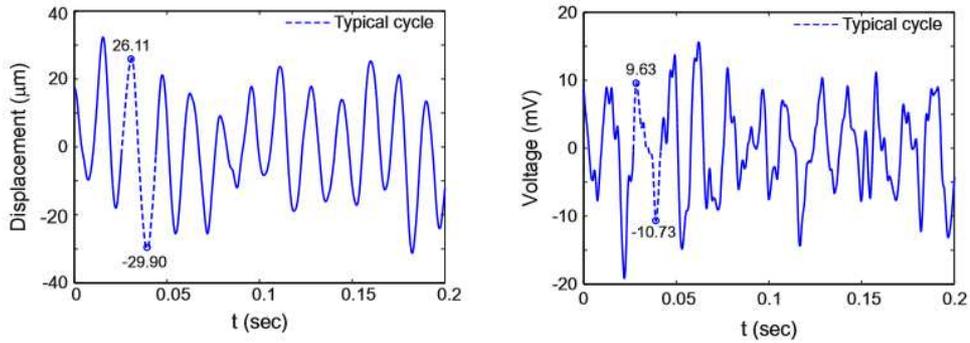

355
356 The wind-belt-like oscillatory energy harvester offered a peak to peak amplitude AC
357 voltage equivalent to 81 mV at frequency of 0.53 kHz, generating from an input of 50
358 kPa of pressure. The Helmholtz-resonator-centred generator reached a peak to peak
359 amplitude AC voltage of 4 mV at frequency of 1.4 kHz, from 0.2 kPa pressure input,
360 corresponding to 5 m/s or 10 mph wind speeds.

361
362 Fig. 11. Schematic plan illustrating the principle of operation of energy harvester in
363 [19]: (a) at rest state; (b) at resonance through wind flow.
364

365 Munaz et al. [20] demonstrated that there was potential for the power generation of
366 the electromagnetic energy harvester via vibrations to be amplified many times over
367 by the introduction of several magnets as the moving mass even if all other
368 experimental variables were fixed. The device generated 224.72 μW in DC power,
369 having 200 Ω load resistance for a 5-magnet system. This device operates at a
370 subtle resonance frequency equivalent to 6 Hz, which was deemed appropriate for
371 handheld devices and remote sensing applications.

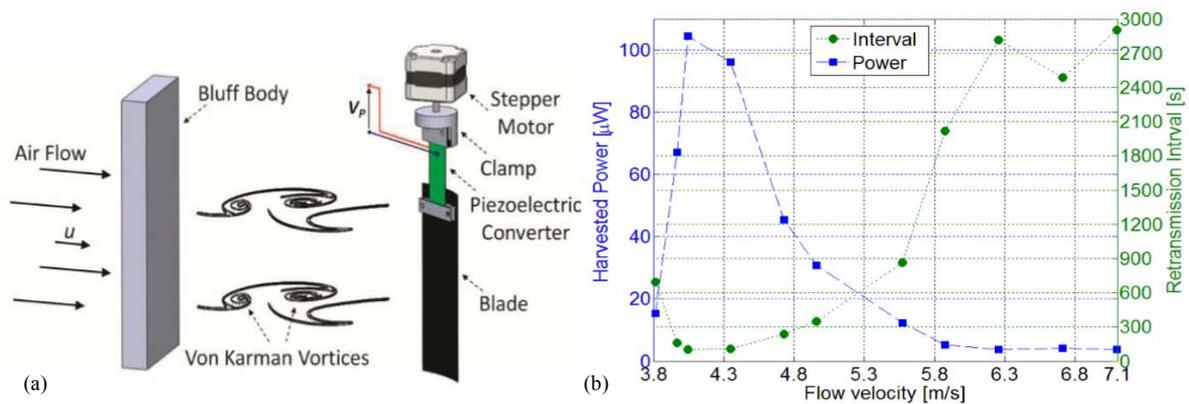

372
373 Wang et al. [21] discussed a study on energy harvesting through vibrations caused
374 by the Karman vortex street through an electromagnetic harvester producing
375 instantaneous power of 1.77 μW under exposure to the vortex street. Figure 12
376 shows the measured displacement history and the open circuit voltage induced by
377 the coil which measured approximately 20 mV peak-to-peak. In the same study it
378 was stated that the vibrations can also be harnessed from other fluid flow - river
379 streams, tire air pressure flow or fluids in mechanical equipment.

380
 381 Fig. 12. (a) Magnet displacement and (b) Induced voltage by the coil for a typical
 382 cycle [21]

383 2.2.2 Piezoelectric Energy Harvesting Devices

384
 385 Demori et al. [22] explored a piezoelectric energy harvesting illustrated in Figure 13
 386 (a) where a stepper motor is attached to a piezoelectric converter that can vary the
 387 beam angle relative to the flow. The output of the energy harvesting system together
 388 with its power conditioning circuit was tested through measurements of the
 389 transmission time versus flow. A peak power of 100 μW was collected and
 390 transmission time of 2 s was measured. A retransmission interval under 2 minutes
 391 was attained. It was noticed that for this system, the highest output was achieved
 392 around flow velocity of 4 m/s, as shown in Figure 13 (b).

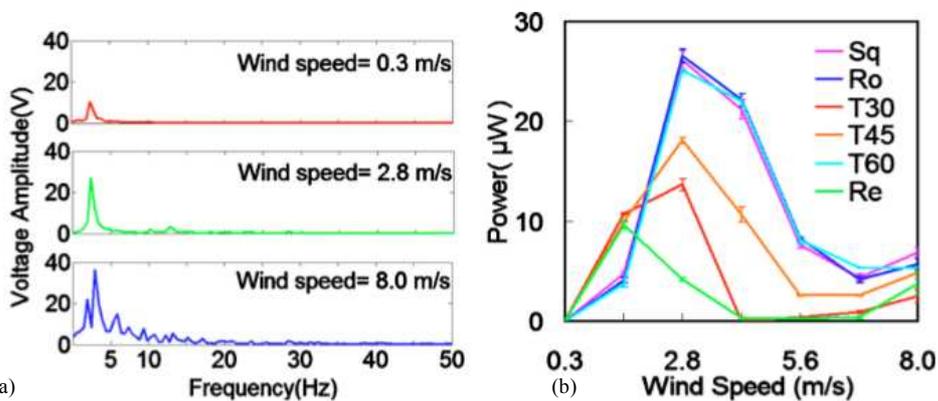

393
 394 Fig. 13. (a) Piezoelectric energy harvesting system schematic (b) Average power
 395 output and retransmission time interval as a function of air flow velocity [22]
 396

397 Shan et al. [23] studied a macrofiber composite piezoelectric energy harvesting
 398 device for water vortex, which generated 1.32 μW power output under liquid water
 399 flow speed of 0.5 m/s, showing the plausibility of using this harvesting technology for
 400 liquid flow as well. Weinstein et al. [24] investigated power from a piezoelectric shaft
 401 influenced by vortex shedding from a bluff cylinder, which generated 200 μW and 3
 402 mW of power at air velocities of 3 m/s and 5 m/s.

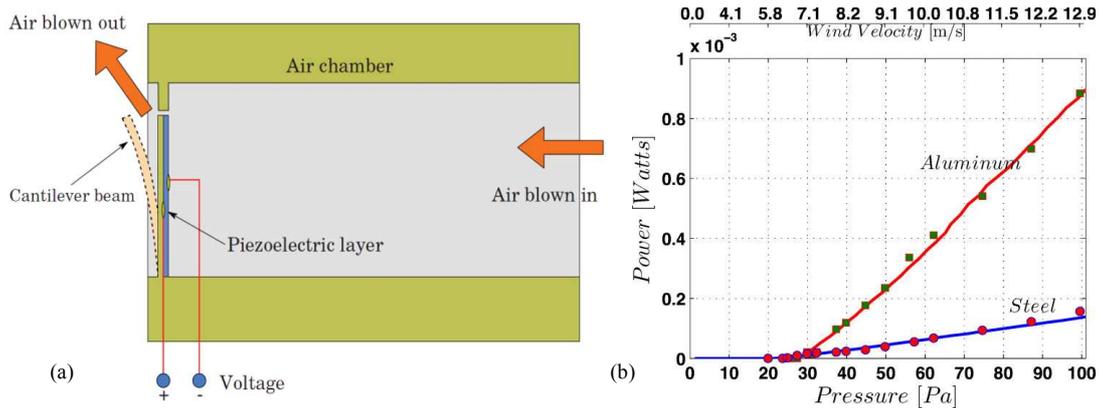

403

404 Li et al. [25] investigated a piezoelectric energy harvesting device which used flexible
 405 piezoelectric materials as “stalks” together with polymer membrane acting as leaf-like
 406 structures. The experiment result confirmed a maximum power output of 615 μW for
 407 an airflow speed of 8 m/s and 5 M Ω resistance while using a two-layer stalk. The
 408 maximum power density was 2036 $\mu\text{W}/\text{cm}^3$ for a single leaf. Furthermore, the work
 409 noted that their energy harvesters demonstrated good power performance
 410 normalized by volume, mass and expenditure. Although their harvesters performed
 411 were not effective in terms of power per swept-area. The study recommended that
 412 the swept-area performance could be enhanced through assembling multiple
 413 harvesters behind one another. Figure 14 shows the performance of the piezo-leaf
 414 where in (b) different shapes of the leaf were tested including square, round,
 415 isosceles triangle with 30° base angle, isosceles triangle with 45° base angle,
 416 equilateral triangle, and rectangle (Sq, Ro, T30, T45, T60 and Re, respectively)

417 (a) Wind response of piezo-leaf with varying wind speeds (b) Power output of
 418 Fig. 14. (a) Wind response of piezo-leaf with varying wind speeds (b) Power output of
 419 the different shapes of piezo-leaf [25]
 420

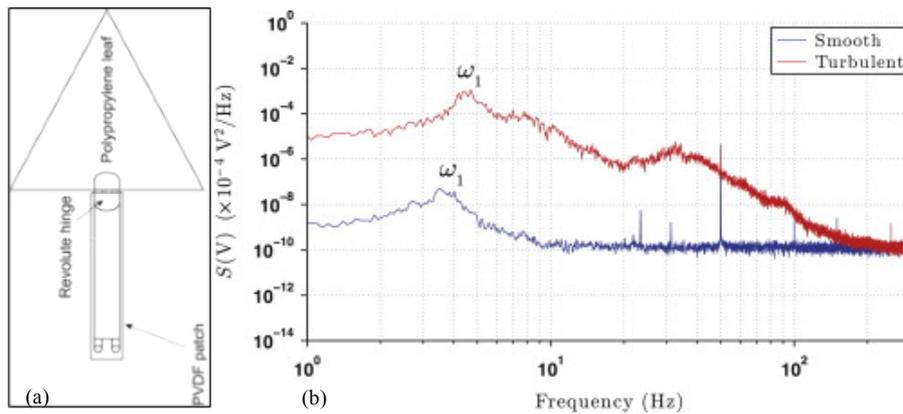

421 St. Clair et al. [26] investigated a micro-generator that utilised flow-generated self-
 422 excited fluctuations. This concept was analogous to a musical harmonica that
 423 produces sounds through vibrations of its reeds when fluid is blown. This device
 424 performed with an power generation from 0.1 to 0.8 mW while operating at airflow
 425 speeds spanning between 7.5 and 12.5 m/s. Figure 15 shows the general working
 426 principle of the device and the maximum power output as a function of air pressure
 427 for two types of beams (Aluminium and Steel) where the curves represent simulation
 428 results and the dots indicate experimental results.

429 Fig. 15. (a) Piezoelectric energy harvester utilising flow-induced oscillations (b)
 430 Maximum power output as function of air pressure for two beam types – Aluminium
 431 and Steel [26]
 432
 433

434 Erturk et al. [27] examined the concept of piezo-aero-elasticity for energy harvesting
 435 using a mathematical model and experiments. The harvester has a 50 cm long
 436 aerofoil that is vertically oriented. Two piezoceramics of type Lead Zirconate
 437 Titanate-5A (PZT-5A) were fastened to two extremities of the aerofoil. Upon
 438 interacting with air, the aerofoil moves and triggers the piezoceramics thereby
 439 generating electric current. The results showed 10.7 mW of power yield for 9.3 m/s
 440 flutter velocity using a resistive load of 100 k Ω load.
 441

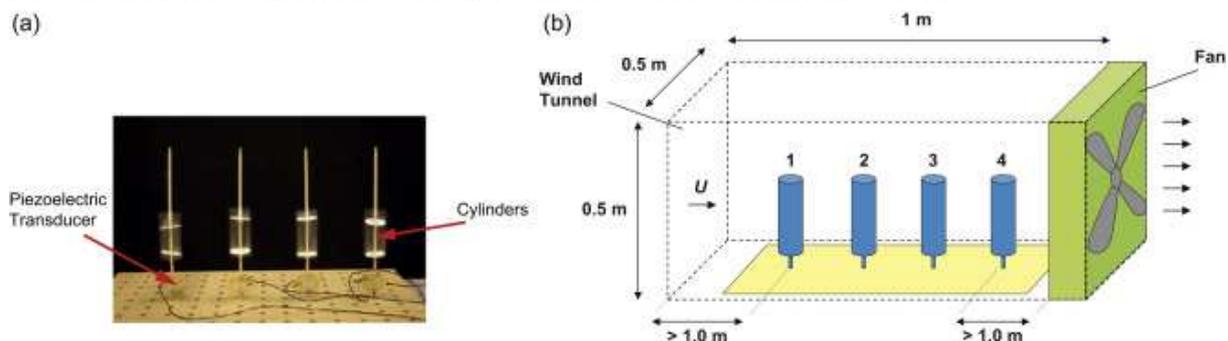

442 Dickson [28] developed a novel deployable flutter energy harvester based on a
 443 structure resembling a tree composed of several “leaves” of piezoelectric devices.
 444 Preliminary experiments demonstrated that power output by the cylinders was low
 445 mainly due to the quality and dimensions of chosen piezoelectric materials. Yet there
 446 were results referred to from Bryant et al. [29] and McCarthy et al. [30] that showed
 447 that there was an optimum spacing for the tandem of devices that triggered trailing
 448 cylindrical energy harvesters to generate appreciably greater energy compared to the
 449 leading harvester. It is noteworthy that this finding was in contrast to that of
 450 conventional horizontal axis wind-turbines (HAWTs), for which tandem orientations
 451 generally avoided because to energy harvesting shortfalls in wakes areas shown by
 452 Burton et al. [31]. Figure 16 shows the leaf-type harvester with its performance under
 453 smooth and turbulent airflows.

454 Fig. 16. (a) The Polyvinylidene-fluoride (PVDF) [28] leaf; and (b) Harvester's voltage
 455 spectral density for smooth and turbulent wind flow of 8 m/s at 135° flow angle [32]
 456
 457

458 The “tree” concept was tested by Li et al. [33]. This harvester with leaves made of
 459 Polyvinylidene-fluoride (PVDF) was subjected to wind speeds from 3 to 8 m/s. The
 460 leaves are triangular in shape. It was earlier discovered in [25] that the triangular
 461 shape provided the highest power output among several different tested shapes. It
 462 was also found out that the energy harvester functioned best when it has flutter
 463 oscillations under the Limit-Cycle Oscillations (LCOs) as opposed to chaotic flutter
 464 [34]. An electroactive area power density, $P_{EAA} \leq 45 \mu\text{W}/\text{cm}^2$ was attained [25] by the
 465 piezoelectric tree, where it was shown in [39] that 296 μW peak power was
 466 harnessed at top speed of 8 m/s.
 467

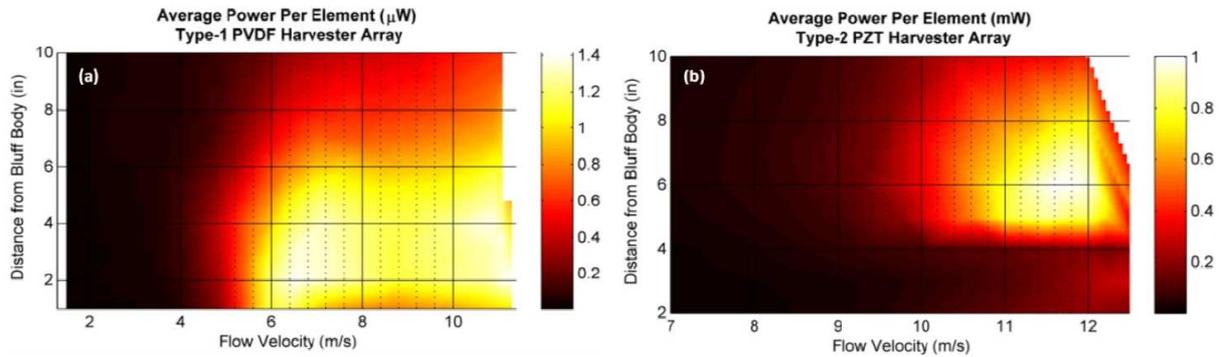

468 Hobbs and Hu [35] developed energy harvesters based on rounded cylinders which
 469 were positioned in groupings at different spacings subject to wind tunnel flow as
 470 shown in Figure 17. These cylinders were fastened to piezoelectric discs close to the
 471 bottom and were allowed to oscillate in the cross-stream direction.

472 Fig. 17. (a) Experimental setup and (b) schematic diagram of parallel circular
 473 cylinders studied by [35]
 474
 475

476 Hobeck and Inman [36] examined energy harvester called “piezoelectric grass”. In
 477 this investigation, several piezoelectric ceramic materials made of PZT were
 478 configured such that there were bending oscillations in the structure near-wake flow.
 479 Power output of 1 mW per PZT beam was attained for a flow speed of about 11.5

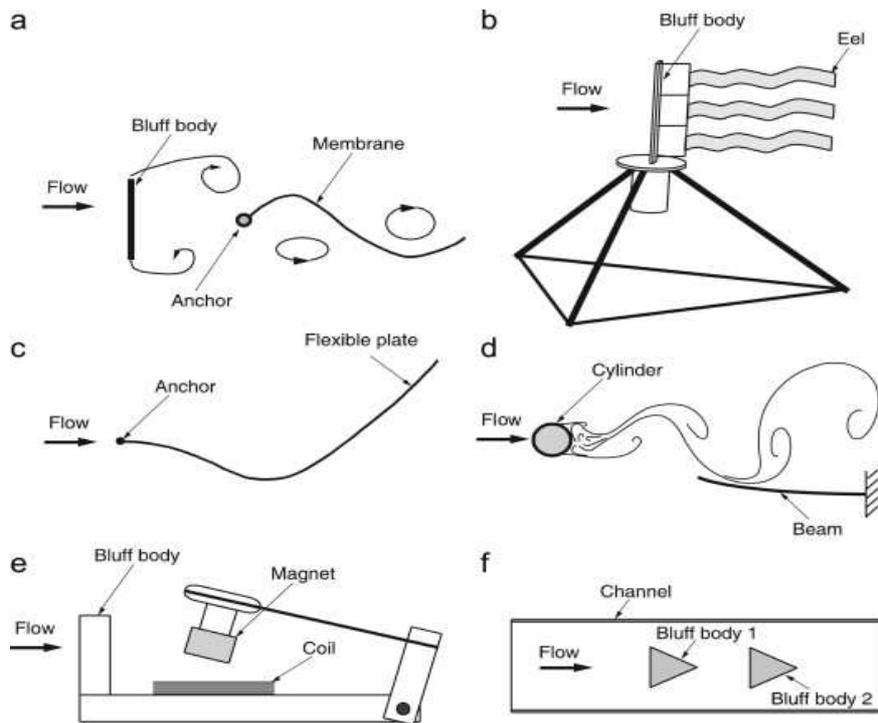

480 m/s, and it was also discovered that optimum turbulence conditions could maximised
 481 the power output. Figure 18 shows how the average power output is related to the
 482 position of the harvester with respect to the bluff body and the velocity of airflow for
 483 two types of harvester arrays – PVDF and PZT. The PZT type generates higher
 484 power output per element in the milliWatt range, as mentioned earlier.

485
 486 Fig. 18. Power output with varying flow velocity and bluff body position for (a) PVDF
 487 harvester array, and (b) PZT harvester array [36]
 488

489 Akaydin et al. [37] investigated energy harvesting system based on piezoelectric
 490 shaft along the trail of a round cylinder subjected to unsteady wind flow. As illustrated
 491 in Figure 19 (d), the shaft is configured to be parallel with respect to the oncoming
 492 wind and was held secured at the downstream edge. The study showed that the gap
 493 between the vortices' circulation and the vortices distance from the shaft had
 494 influence on the output power was. The greatest power was around 4 μ W with
 495 Reynolds number of approximately 14800 at the shaft's resonant frequency.

496
 497 A known mechanism for boosting pressure variation amplitudes occurring in a vortex
 498 street was to utilise an array of structures in group configuration as shown in Figure
 499 19 (f). [38] and [39] both stated that two bluff structures in arranged in such a way
 500 could increase the hydrodynamic oscillations created by the phenomenon of vortex
 501 shedding. Consistency of the vortices was also enhanced when two bluff structures
 502 were present instead of a single one [40].

Song et al. [44] investigated a piezoelectric device based on composite cantilever immersed in water instead of air illustrated in Figure 20. Highest power output of the harvester was observed to be 21.86 μ W which was attained at a water flow of 0.31 m/s.

Matova et al. [45] described an energy harvester containing an enclosed piezoelectric device inside a *Helmholtz resonator*, as shown in Figure 21 (a). It was discovered in the study that enclosed harvesters performed better than exposed harvesters because the enclosure negated the viscous effect of air within the Helmholtz cavity and guaranteed that only the fluctuation stimulated the harvester. Tests revealed that the energy harvester produced a peak power of 2 μW subjected to air flow speed of 13 m/s at a frequency of 309 Hz. However, a disadvantage of the Helmholtz resonator was its resonant frequency's dependence to the surrounding temperature. This entailed that this type of harvester could only be utilised in settings with steady temperature ranges, otherwise the harvester must be redesigned to operate at a wider frequency range. Figure 21 (b) shows the generated power of the harvester for a constant flow velocity of 14 m/s and load resistance of 3.3 M Ω with varying cavity volume of the Helmholtz resonator.

 532

533 2.2.3 Triboelectric and Hybrid Generators

534 Xie et al. [46] proposed *triboelectric nanogenerator* (TENG) that was able to harvest
 535 miniature wind energy ambient in normal human habitats developed utilising common
 536 materials. This system had a rotating part that enabled the sweeping motion of
 537 several triboelectric films called polytetrafluoroethylene (PTFE), thereby making
 538 alternating contact and separation with Aluminium sheets. This process of cyclical
 539 physical contact and disconnection between distinct planes with opposing
 540 triboelectric charges was responsible for generating an induced voltage across two
 541 electrodes, therefore pushing flow of electrons in an alternating current. This
 542 particular rotary triboelectric nanogenerator (R-TENG) was able to achieve a peak
 543 power of 62.5 mW, a peak power density of about 39 W/m² at airflow speeds of
 544 around 15 m/s, from approximately 250 V open-circuit voltage with a 0.25 mA short-
 545 circuit current. This investigation had shown that triboelectric nanogenerators could
 546 work hand-in-hand with wind power.

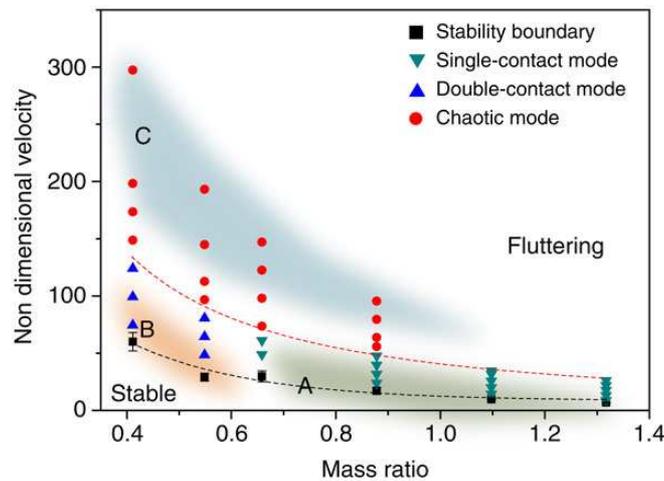

547
 548 Liang et al. [47] investigated a *multi-unit transparent triboelectric nanogenerator* (MT-
 549 TENG), which is intended to harvest energy from ambient water movements like rain
 550 water as illustrated in Figure 22. The peak instantaneous power density was
 551 measured at 27.86 mW/m². This value is 11.6 times larger than the output of a single
 552 transparent TENG of the same operating size.

553

554 Fig. 22. Working mechanism leading to the improved efficiency of the MT-TENG;
555 inset shows potential application in buildings [47]
556

557 Bae et al. [48] studied a flutter-based wind harvesting triboelectric generator. This
558 flutter-driven triboelectric generator (FTEG) is relatively small being only 7.5 cm long
559 and 5 cm wide. Nevertheless it demonstrated instantaneous outputs of approximately
560 200 V and current of 60 μA under 15 m/s wind speeds equivalent to 158 Hz. This
561 corresponds to 0.86 mW of output power. The authors also characterised the
562 generator by its different modes of operation based on its components' contact type.
563 There are three modes they discovered: single, double and chaotic. The transitions
564 between modes are shown in Figure 23, wherein the transition from single to double-
565 contact mode ensues corresponding to decreasing mass ratio.

566
567 Fig. 23. Velocity vs. mass ratio plot of the relationship between flag and plate
568 behaviour showing the different contact modes [48].
569

570 571 2.3 Challenges

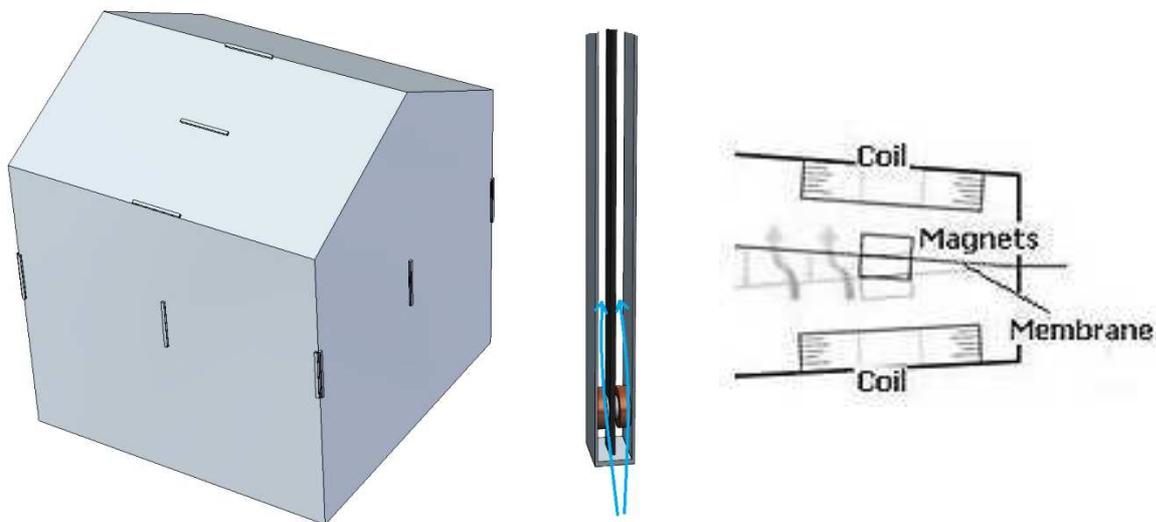

572
573 Previous studies about the building environment's potential for wind energy
574 harvesting highlighted the need for detailed and accurate analysis of wind flow
575 around buildings. To utilise the effect of wind acceleration above or around buildings
576 and to be able to determine the appropriate type of wind energy technology to be
577 installed sufficient integration analysis has to be conducted. In addition, there is the
578 challenge to analyse optimum position of the wind energy harvesters. Accurate
579 simulations will lead to more information that can result to better decisions [2].
580

581 No previous work studied the integration of low-energy vibration harvesting devices
582 in buildings or structures. Most studies for these energy harvesters are carried out in
583 laboratory settings. There is also a lack in numerical studies about these energy
584 technologies. There is a lack in research about the applications of these harvesters in
585 the urban environment. Most theoretical works use unrealistic boundary conditions
586 like the utilisation of uniform flow. Currently very few studies were done involving

587 actual field tests with real-world conditions. If low-energy harvesters are to become
588 widely commercial, field tests observable by the public need to be increased. This
589 study will address this by carrying out an urban flow simulation of a small building
590 integrated with low-energy harvesters and assess the impact of varying outdoor wind
591 conditions.
592

593 3. CASE STUDY: ANALYSIS OF THE INTEGRATION WITH THE BUILT 594 ENVIRONMENT

595
596 The work will investigate the effect of various external conditions and device
597 locations on the performance of the aero elastic belt. The simulation will use a gable-
598 roof type building model with a 27° pitch as shown in Figure 24. The atmospheric
599 boundary layer (ABL) flow will be used for the simulation of the approach wind. The
600 three-dimensional Reynolds-averaged Navier-Stokes (RANS) equations together
601 with the continuity and momentum equations will be solved using ANSYS FLUENT
602 16 for obtaining the velocity field and also pressure field. Sensitivity analyses for the
603 CFD grid resolutions will be executed for verification of modelling. In addition, the
604 results of the flow around the buildings and surface pressure coefficients will be
605 validated with previous experimental work. The study will utilise regression analysis
606 and experimental data [6] to estimate the power output of the aero-elastic belt. The
607 coil used in the transducer are composed of 38 American wire gauge (awg)
608 enamelled wire with 150 turns and approximately 25 ohms internal resistance [49].
609 Figure 24 shows the location of the aero elastic belt around the building geometry.

610
611 Fig. 24. CAD geometry of building with aero-elastic belt devices
612

613 3.1 Computational Fluid Dynamics modelling

614 The fundamental assumptions for the numerical simulation involve a 3D, fully
615 turbulent, and incompressible flow. The flow was modelled by making use of the
616 standard $k-\epsilon$ turbulence model, which is a well-established research technique
617 regarding airflows surrounding buildings [50]. The Finite Volume Method (FVM) was
618 utilised with the CFD model together with the Semi-Implicit Method for Pressure-

619 Linked Equations (SIMPLE) velocity and pressure coupling algorithm using the
 620 second order upwind discretisation. The governing equations are the continuity
 621 equation (Eqn. 7), momentum equation (Eqn. 8) and energy equation (Eqn. 9). The
 622 standard k- ϵ transport model was employed to classify the turbulence kinetic energy
 623 and flow dissipation rate within the simulation model. The transport equations are
 624 shown in Eqn. 10 and Eqn. 11.
 625

$$\frac{\partial}{\partial t}(\alpha_q \rho_q) + \nabla \cdot (\alpha_q \rho_q \vec{v}_q) = \sum_{p=1}^n (\dot{m}_{pq} - \dot{m}_{qp}) + S_q \quad (7)$$

$$\frac{\partial}{\partial t}(\alpha_q \rho_q \vec{v}_q) + \nabla \cdot (\alpha_q \rho_q \vec{v}_q \vec{v}_q) = -\alpha_q \nabla p + \nabla \cdot \bar{\tau}_q + \alpha_q \rho_q \vec{g} + \sum_{p=1}^n (\vec{R}_{pq} + \dot{m}_{pq} \vec{v}_{pq} - \dot{m}_{qp} \vec{v}_{qp}) + (\vec{F}_q + \vec{F}_{\text{lift},q} + \vec{F}_{\text{vm},q}) \quad (8)$$

$$\frac{\partial}{\partial t}(\alpha_q \rho_q h_q) + \nabla \cdot (\alpha_q \rho_q \vec{u}_q h_q) = \alpha_q \frac{\partial p_q}{\partial t} + \bar{\tau}_q \cdot \nabla \vec{u}_q - \nabla \cdot \vec{q}_q + S_q + \sum_{p=1}^n (Q_{pq} + \dot{m}_{pq} h_{pq} - \dot{m}_{qp} h_{qp}) \quad (9)$$

626
 627 where; \vec{v}_q denotes the velocity of phase q and \dot{m}_{pq} and \dot{m}_{qp} characterizes the mass
 628 transfer from the pth to qth phase and vice-versa. $\bar{\tau}_q$ denotes the qth phase stress-
 629 strain tensor. h_q denotes the specific enthalpy of the qth phase and \vec{q}_q denotes the
 630 heat flux. Q_{pq} is the heat exchange intensity between the pth and qth phases and h_{pq}
 631 is the interface enthalpy. S_q denotes the source term.
 632

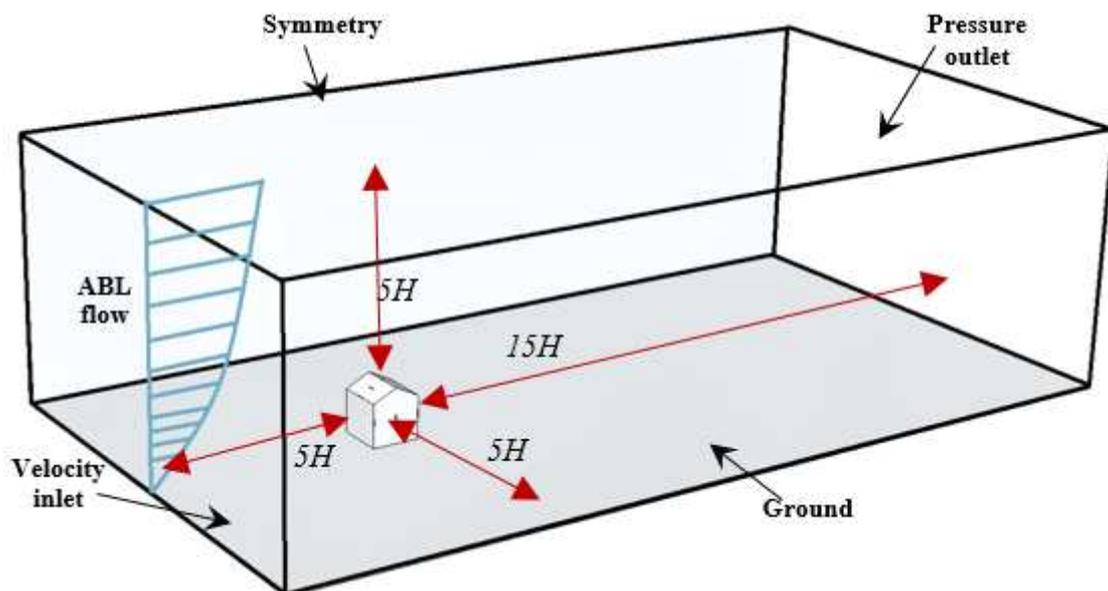

$$\frac{\partial}{\partial t}(pk) + \frac{\partial}{\partial x_i}(\rho k u_i) = \frac{\partial}{\partial x_j} \left[\left(\mu + \frac{\mu_t}{\sigma_k} \right) \frac{\partial k}{\partial x_j} \right] + G_k + G_b - \rho \epsilon - Y_M + S_k \quad (10)$$

$$\frac{\partial}{\partial t}(\rho \epsilon) + \frac{\partial}{\partial x_i}(\rho \epsilon u_i) = \frac{\partial}{\partial x_j} \left[\left(\mu + \frac{\mu_t}{\sigma_e} \right) \frac{\partial \epsilon}{\partial x_j} \right] + C_{1\epsilon} \frac{\epsilon}{k} (G_k + C_{3\epsilon} G_b) - C_{2\epsilon} \rho \frac{\epsilon^2}{k} + S_\epsilon \quad (11)$$

633
 634 where; G_k denotes turbulence kinetic energy generation due to the mean velocity
 635 gradients, G_b denotes turbulence kinetic energy generation due to buoyancy. Y_M
 636 denotes the contribution of fluctuating dilatation in compressible turbulence to the
 637 overall dissipation rate. $C_{1\epsilon}$, $C_{2\epsilon}$ and $C_{3\epsilon}$ are constants, σ_k and σ_e are the turbulent
 638 Prandtl numbers for k and ϵ . S_k and S_ϵ are the source terms.

639 The geometry (Figure 25) was designed making use of an academic standard CAD
640 tool and then exported into ANSYS Geometry to generate a computational model.
641 The shape of the building was based on [51], which is a gable roof type building with
642 a roof pitch of 26.6° . The overall dimension of the building was 3.3m (L) x 3.3m (W) x
643 3m (H). The fluid volume was isolated from the solid model to generate a
644 computational domain. The fluid domain contained an inlet on one side of the
645 domain, and an outlet on the opposite boundary wall.

646 The COST 732 guideline [52] for environmental wind flow studies was used as the
647 basis for computational domain size and model location. According to the guidelines,
648 for a single structure with the height H , the horizontal distance separating the
649 sidewalls of the structure and side boundaries of the computational domain must be
650 $5H$. Similarly, the vertical distance separating the roof and the top of domain must
651 also be $5H$. Along the direction of the flow, the distance between the inlet and the
652 façade of the building must be $5H$. The distance between the leeward side and outlet,
653 however, must be $15H$ to allow for flow re-development behind the wake region. This
654 is also considering that for steady RANS calculations, fully developed flows are
655 generally assumed as the boundary condition [52].

656
657 Fig. 25. Computational domain of building with aero-elastic belt devices
658

659 Due to the complex nature of the model, a non-uniform mesh was utilised for volume
660 and surfaces of the computational domain [53]. The generated computational mesh
661 of the building model is shown in Figure 26. The grid was improved and refined
662 according to the relevant critical areas for the simulation e.g. the aero-elastic belt.
663 The scales of the mesh element were stretched smoothly to resolve the areas with
664 high gradient mesh and to enhance the precision of the results. The inflation factors
665 were adjusted with respect to the intricacy of the geometry face elements. This was
666 employed to generate a finely resolved mesh perpendicular to the wall and coarse
667 mesh parallel to it [54].

Sensitivity analysis was performed in order to confirm the computational modelling of the building integrated with the aero-elastic belt. The computational grid was established on a sensitivity analysis which was conducted by performing supplementary simulations with the same domain and boundary conditions but with various grid sizes. This procedure then enlarged the number of elements from 2.44 M elements (coarse) to 4.90 M elements (fine). The mean value of the wind speed in the vertical line of the R1 belt was invoked as the error gauge (Figure 27 (b)). The maximum error among the fine mesh and medium mesh was 3.4% or ± 0.08 m/s while the mean error was 1%. Therefore, the redundancy of model simulation with finer mesh had no significant effects on the solutions.

The boundary conditions were specified according to the AIJ guidelines [55]. The airflow velocity profile and turbulent kinetic energy (TKE) were enforced on the inlet region which were based on [50], with the stream-wise velocity of the incident airflow conforming to the power law with an alpha equal to 0.25. This exponent corresponds to a sub-urban terrain (See Figure 27). The ϵ values for the k- ϵ turbulence model were obtained through the assumption of a local equilibrium of $P_k = \epsilon$ [50]. Standard wall functions [56] were invoked for wall boundaries excluding the ground. The ground region had adjusted wall functions relying on roughness values [57]. Based on literature [57], this has to stipulated by an equivalent sand-grain roughness height k_s and roughness constant C_s . The non-homogeneous of the ABL in the horizontal dimension was limited by a suitable sand-grain roughness height and roughness constant adapted for the inlet profiles, obeying the equation of [58] :

$$k_s = \frac{9.793z_0}{C_s} \quad (12)$$

695
696
697
698

where z_0 is the aerodynamic roughness height for sub-urban topography. Sand-grain roughness height was set to 1.0 mm and roughness constant was set to 1.0 [51]. The side walls and top wall of the domain were fixed as symmetry. This indicated zero velocity in the normal direction and zero gradients for all pertinent variables at the

699 side and top walls. Zero static pressure was utilised for the outlet boundary. The
 700 boundary conditions are reviewed in Table 1.

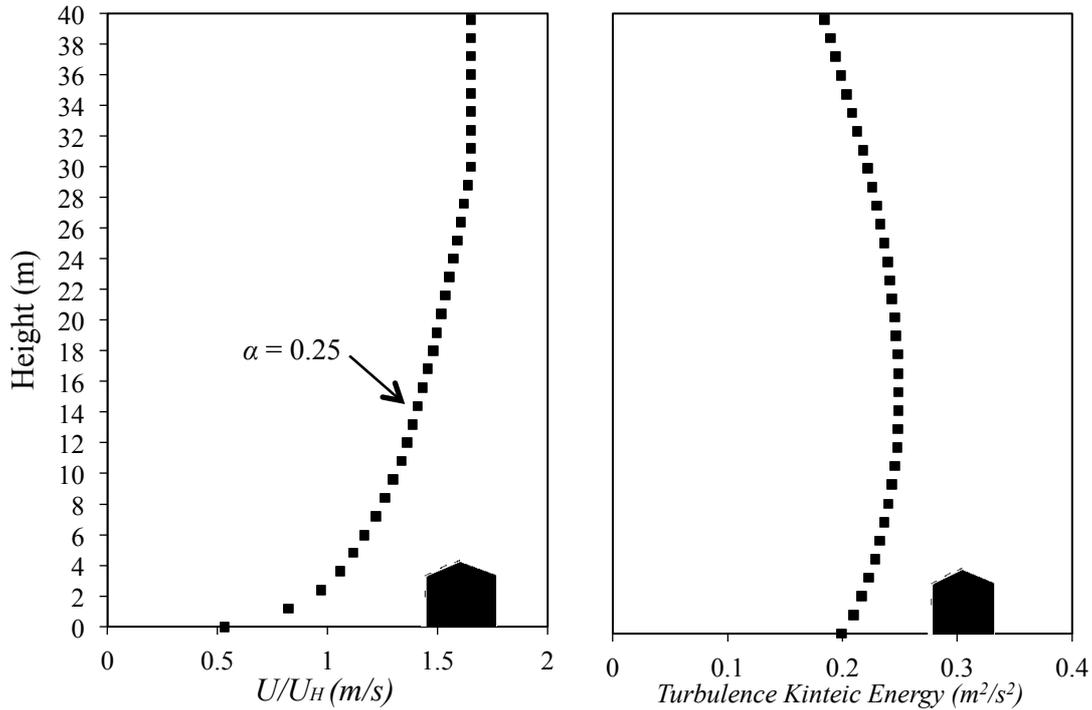

Fig. 27. (a) Velocity profile (b) TKE profile of approach wind flow [51]

Table 1. Summary of boundary conditions for the CFD model

Boundary condition	Set value
Algorithm	SIMPLE
Time	Steady state
Solver type	Pressure based
Discretisation Scheme	Second order upwind
Turbulence model	Standard k-epsilon
Near wall	Standard wall functions
Velocity inlet	ABL profile (See Figure 27)
Pressure outlet	0 Pa

705 The solution convergence and pertinent variables were observed and the solution
 706 was considered to be complete upon observation of invariant iterations. Furthermore,
 707 property conservation was also tested if attained for the converged solution, which
 708 was executed by running a mass flux balance. This selection was obtainable from the
 709 FLUENT flux report panel which permits the calculation of mass flow rate for
 710 boundary zones. For the current model, the mass flow rate balance was lower than
 711 the required value equivalent to a value less than 1% of minimum flux through
 712 domain boundaries, i.e. inlet and outlet.
 713

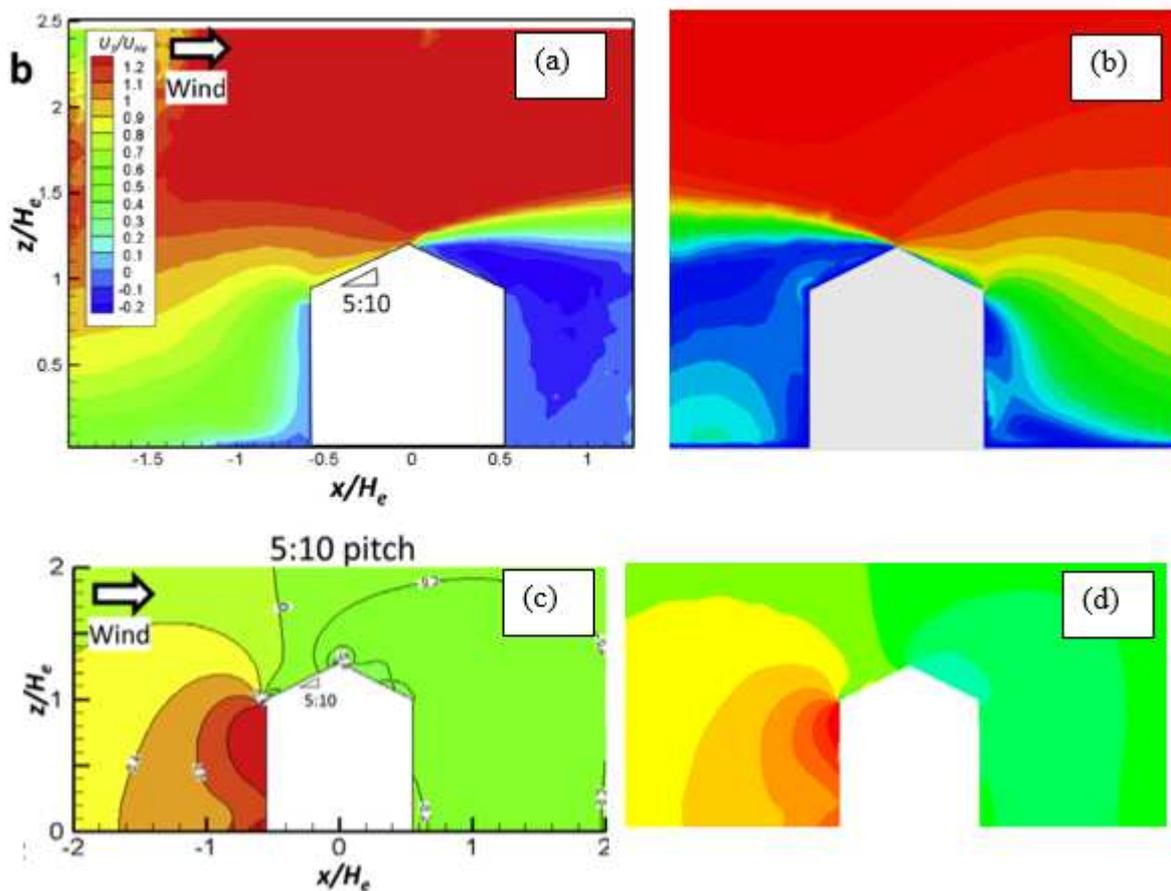

714 3.2 Estimation of wind power

715 The study utilised regression analysis using a polynomial curve of degree three to
 716 extrapolate power output given integral-value wind speed. Experimental data from [6]
 717 was used, with varying wind speed and the corresponding output power, using the

718 optimal load and tension for an aero-elastic belt. A degree three polynomial is
 719 analogous to the fundamental equation for wind power making the choice for this
 720 polynomial type more sensible. Regression analysis was able to obtain an R-squared
 721 value of 0.9666. Using the manufacturer's specifications, cut-in wind speed is limited
 722 to 3 m/s. Therefore in order to extract results using the same aero-elastic belt,
 723 reconfiguration of the belt has to be done on installations on areas of the buildings
 724 with wind speeds lower than 3 m/s. This investigation simulated a gentle breeze,
 725 which is category 3 in the Beaufort wind force scale.

726 3.3 Method validation

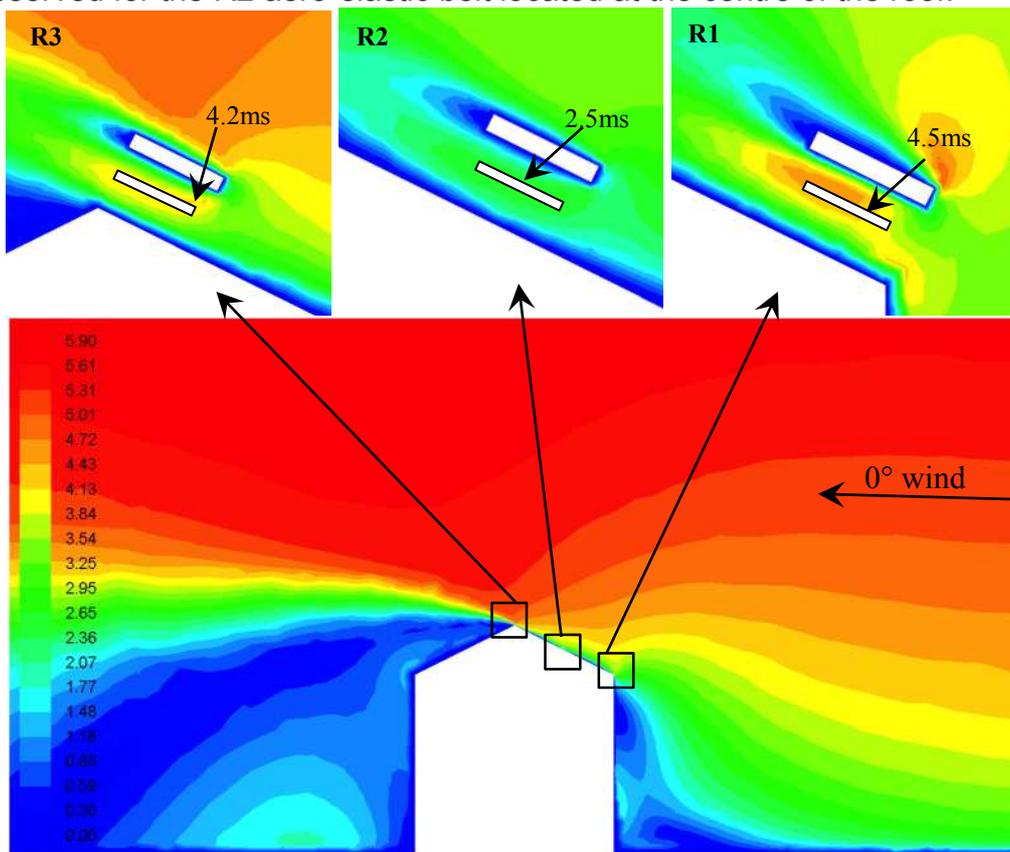

727 Figure 28 (a) and (b) show a comparison between the experimental PIV results of
 728 [51] and the current modelling values for the airflow speed distribution around the
 729 building model. The values for the airflow speed close to the windward wall seem to
 730 be at a lower speed in the model compared to the PIV results, however a similar
 731 pattern was observed for most areas particularly close to the roof. Figure 28 (c) and
 732 (d) show a comparison between the prediction of the current model and [51] of the
 733 pressure coefficient distribution around the building model.

734 Fig. 28. (a) PIV measurements of velocity [51] (b) velocity distribution in the current
 735 model (c) pressure coefficient result [51] (d) pressure coefficient distribution in the
 736 current model.
 737

738 **4. RESULTS AND DISCUSSION**

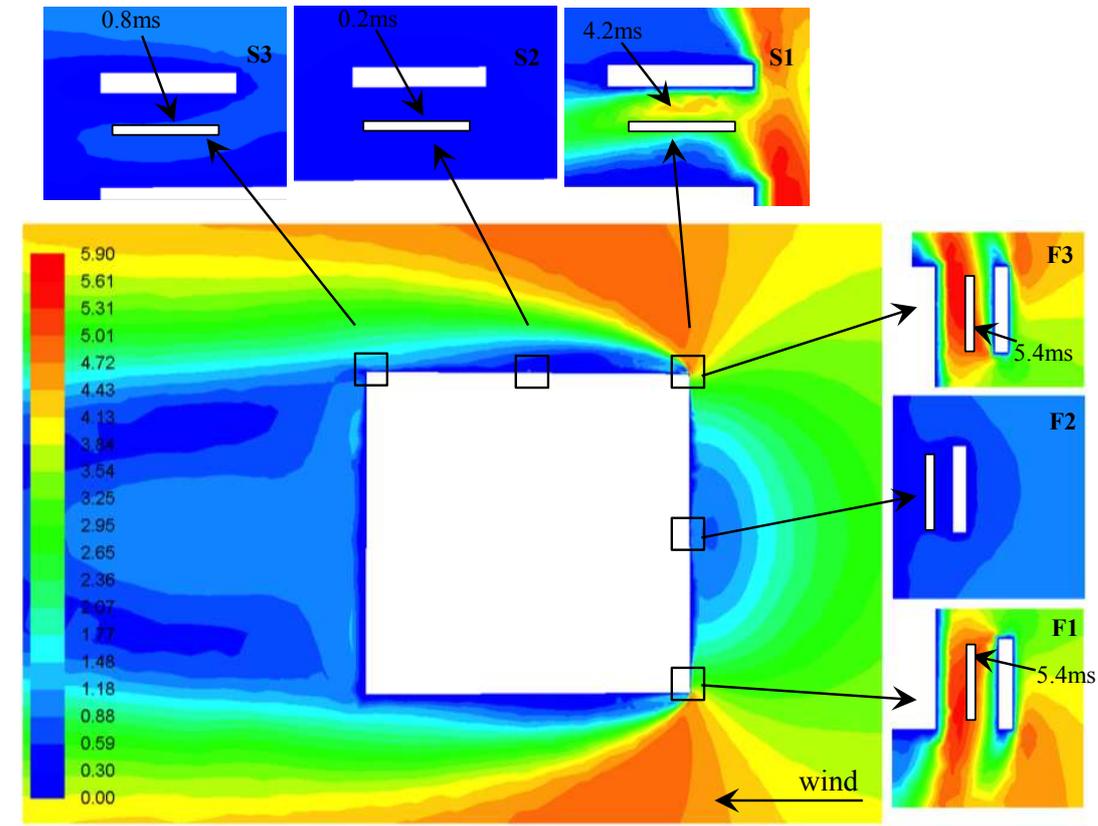

739 Figure 29 displays the contours of the velocity field for the side view cross-sectional
740 area within the computational domain denoting the airflow distribution around the
741 building integrated with aero-elastic belt. On the left part of the plot the scale of
742 airflow speed is displayed in m/s. Colour coding was employed to better illustrate the
743 fluid domain contour plots which range from 0 to 5.9 m/s. As observed, the incident
744 wind flowed from the right side of the domain and subsequently the airflow decreased
745 in speed as it moved towards the building and was then lifted upwards. Regions of
746 flow separation were detected on the lower windward side of the structure and also at
747 the leeward side of the building and roof. Zoomed in views of the velocity distribution
748 around the aero-elastic belt R1, R2 and R3 are shown on top of the diagram. The
749 results showed that the shape and angle of the roof had a significant influence to the
750 performance of the aero-elastic belt. In the diagram, it is clear that locating the device
751 at the leeward side of the roof will result in little to no energy generation due to the
752 low wind speeds in this area. However, it should be noted that this was not the case
753 for other wind angles, for example when the wind is from the opposite direction.
754 Therefore, location surveying, wind assessment and detailed modelling are very
755 important when installing devices in buildings. At wind velocity (U_H) 4.7 m/s and 0°
756 wind direction, the airflow speed in R1 was the highest at 4.5m/s while the lowest
757 was observed for the R2 aero-elastic belt located at the centre of the roof.

758 Fig. 29. Contours of velocity magnitude showing a cross-sectional side view of the
759 building
760
761

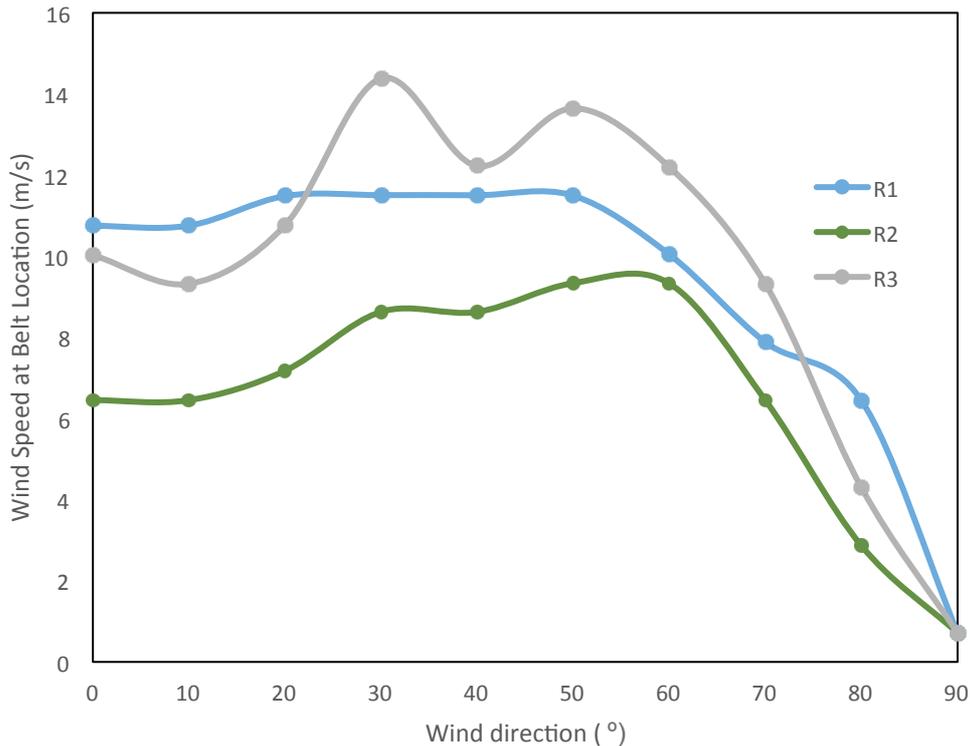

762 Figure 30 displays the top view cross-section area for the velocity contours within the
763 computational domain indicating the airflow distribution around the building integrated

764 with aero-elastic belt. The incident wind flowed from the right border of the domain
 765 and the airflow decreased in speed as it flowed closer to the building and accelerated
 766 as it flowed around the corners. Regions of flow separation were detected on the
 767 leeward and side areas of the building. Zoomed in views of the velocity distribution
 768 around the aero-elastic belt F1-F3 and S1-S3 are shown on top and right side of the
 769 diagram. At wind velocity (U_H) 4.7 m/s and 0° wind direction, the airflow speed in F1
 770 and F3 were the highest at 5.4m/s while the lowest was observed for the S2 and F2
 771 aero-elastic belts located at the airflow recirculation zones.

772
 773 Fig. 30. Contours of velocity magnitude showing a cross-sectional top view of the
 774 building

775 Figure 31 compares the maximum air velocity speed measured at the belt location for
 776 roof installations R1, R2 and R3 at various wind directions. These setups behaved in
 777 a trend similar to each other, but the notable highest velocities were attained from the
 778 R3 or apex installation. These setups had peak velocity values occurring at the
 779 region between 30° to 60° orientation, with the maximum value obtained at 30° . There
 780 was significant speed decrease after 60° that could be attributed to the belt frame
 781 corners which impeded the wind from flowing through the belt region and therefore
 782 would reduce its performance or not allow the belt to flutter

783

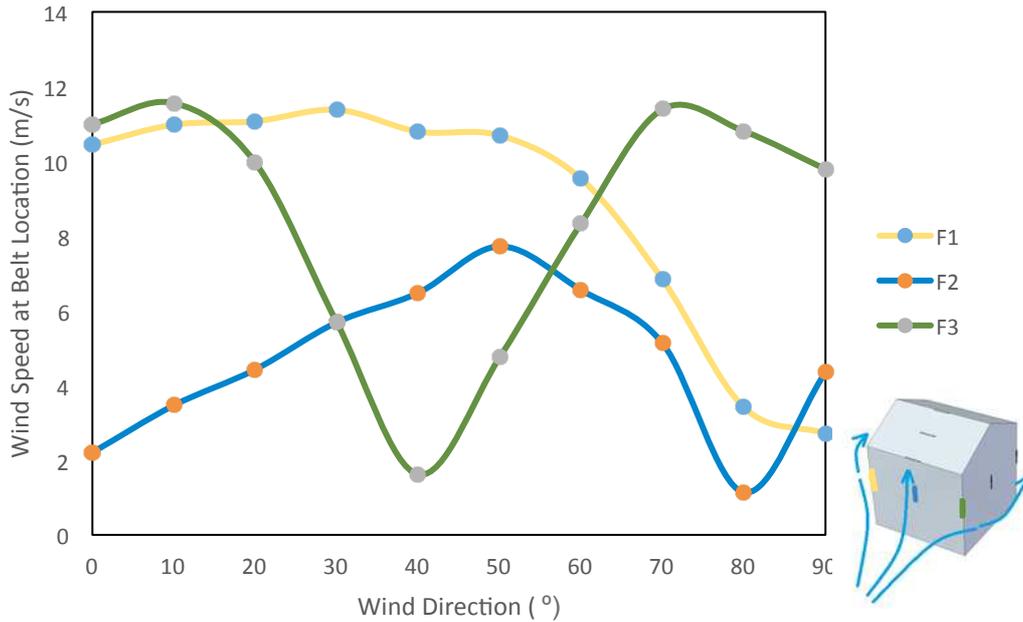

784 Fig. 31. Effect of wind direction on the wind speed at belt located on the roof for
 785 various wind angle of approach with outdoor wind $U_H = 10$ m/s

786

787 Figures 32 and 33 compare the maximum air velocity speed measured at the belt
 788 location for the windward and side installations, respectively at various wind
 789 directions. When comparing the two figures it was observed that the plot of F3 had a
 790 similar trend with the S1 belt which showed a significant performance drop in terms
 791 of velocity between 20-60°. This was also due to the frame of the wind belt which
 792 impeded the wind from flowing through the belt region and therefore would reduce its
 793 performance or not allows the belt to flutter

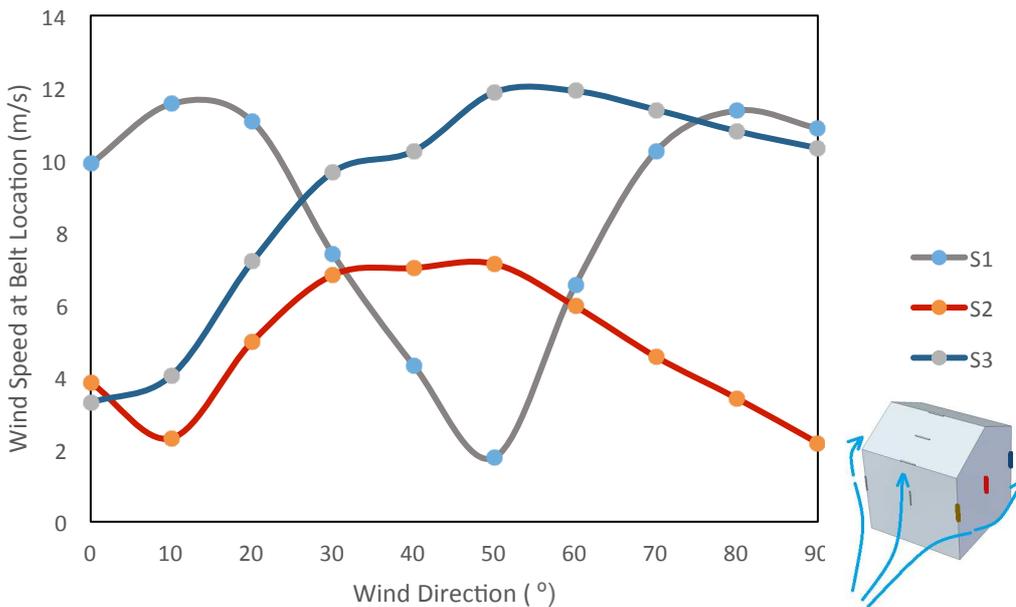

794

795 While the plot of F1 was a mirrored of S3, and F2 was mirrored S2. There is some
 796 symmetry that can be expected as observing the locations in Figure 24. It is not a
 797 perfect symmetry due to the roof shape having some effect on airflow. Looking at the
 798 location with highest velocity values for the front side of the building, there was a
 799 significant decrease in velocity from 10° to 40°, accounting for approximately 83%
 800 speed reduction, and same increase in speed was observed from 40° to 70°. For the
 801 side installation S1 the tipping point was at 50° where the change in angle exposure
 802 past this point marked significant increase in velocity. From the results it was clear
 803 that both the location of the device and wind direction had a significant effect on the
 804 air speed achieved at the belt location. Therefore a complete detailed analysis of
 805 these factors should be carried out when integrating wind belts to buildings to ensure
 806 that the performance is optimised and also minimised the number of belts integrated
 807 to the building.

808

809 Fig. 32. Effect of wind direction on the wind speed at belt located on the windward
 810 side of building with outdoor wind at $U_H = 10$ m/s

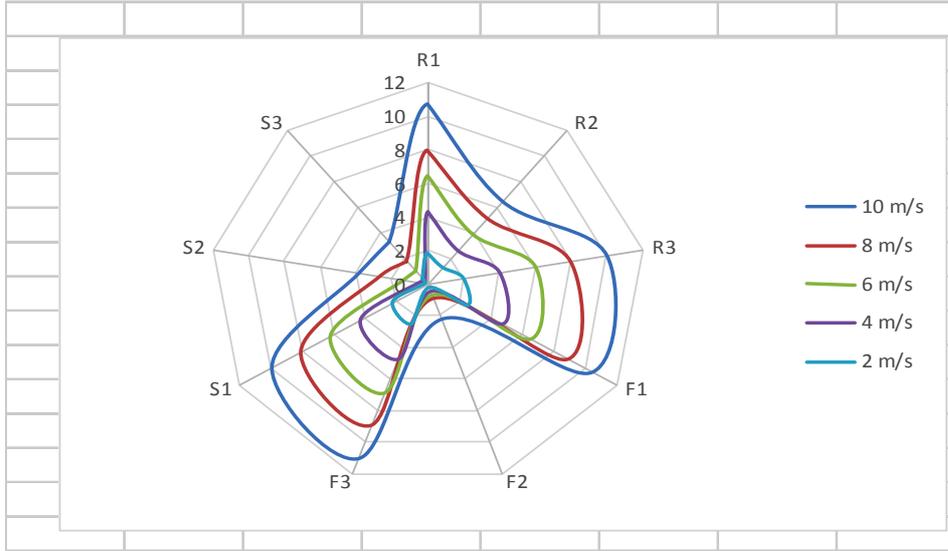

811

812 Fig. 33. Effect of wind direction on the wind speed at belt located on the side of
 813 building with outdoor wind at $U_H = 10$ m/s

814

815 Figure 34 illustrates the effect of different outdoor wind speed U_H values of 2, 4, 6, 8,
 816 and 10 m/s at 0° wind direction on the air speed achieved at the belt location. Similar
 817 trend was observed for all the curves with the highest speed achieved in R1 and F3
 818 and lowest speed achieved in F2 and S2. The increase in the velocity profile
 819 corresponded to a proportional increased for the wind speed for all the belt locations.

820

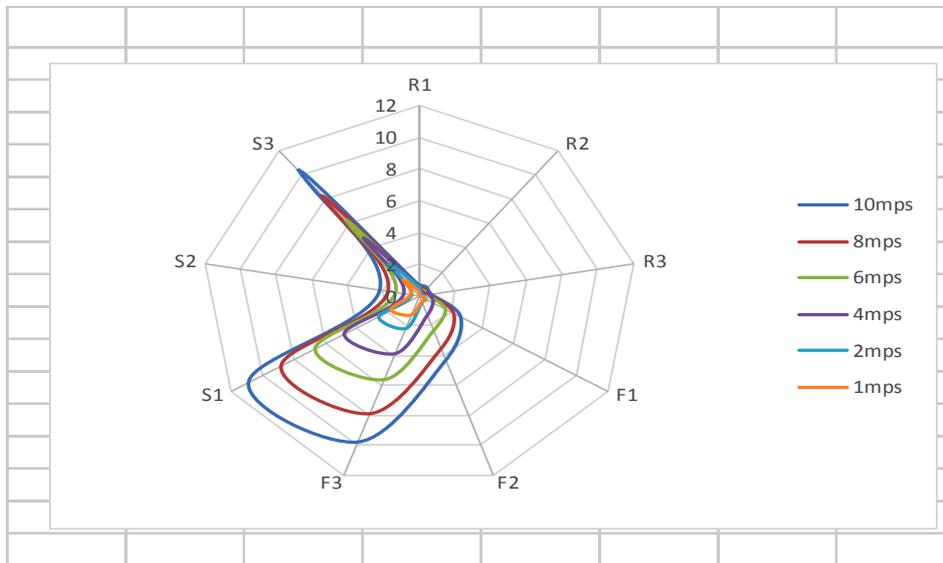

821

822 Fig. 34. Wind speeds gathered at belt position for various mounting locations for 0°
823 wind angle of approach
824

825

826 Figure 35 depicts velocity results for 90° wind angle approach. At this angle the
827 output of the roof installations were overtaken by those in the front and side, most
828 notably by F3, S1 and S3 mainly because of the geometry of the belt frame. The
829 frame restricts airflow in the perpendicular direction to the belt. Therefore for
830 locations with this type of prevailing wind direction it will be better for the aero-elastic
831 belts to be integrated through the front and side edges of the building.

831

832

833 Fig. 35. Wind speeds gathered at belt position for various mounting locations for 90°
834 wind angle of approach
835

836

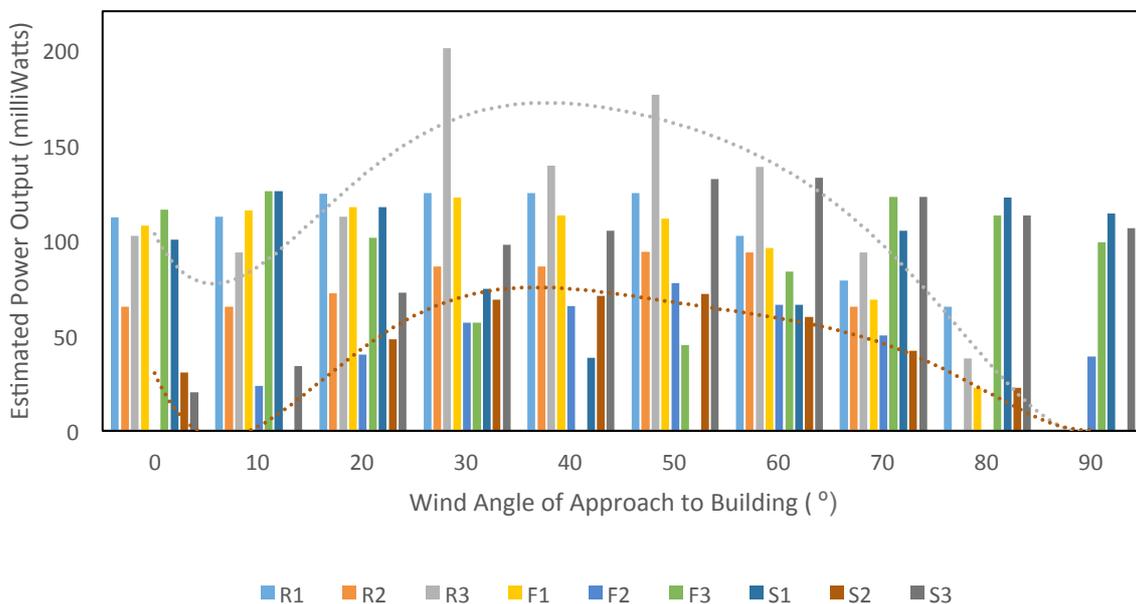

837 Figure 36 compares the estimated output of the device at various locations and wind
838 directions of 0 to 90°, in increments of 10 degrees while maintaining a uniform
839 outdoor wind velocity ($U_H = 10 \text{ m/s}$). F1, F2 and F3 represent the aero-elastic belt
839 mounted on the front face of the building; S1, S2 and S3 represent those on the side

840 face, while R1, R2 and R3 are those for the roof locations. As observed, the highest
 841 power output comes from location R3 – the apex of the building – with an estimated
 842 output of 200.54 mW, resulting from wind speed that accelerated up to approximately
 843 14.4 m/s, approximately 37.5% speed-up at the particular height. This occurred for
 844 an incoming wind 30° relative to the building facade.

845
 846 Depending on prevailing wind direction of the area, the installation location of the belt
 847 can be determined. The green trendline represents the power output trend for R3, the
 848 location with the highest total power generation summed over 0 to 90 degrees. The
 849 brown trendline shows the trend for S2, the location with the lowest summed power
 850 generation over the same angular range.

851
 852 Secondary to the building apex, locations on the edge also provide well above-
 853 average power output. Based on the simulated conditions, locations S3, F1 and R1
 854 should be optimum locations for building integration of the aero-elastic belt,
 855 considering the power averages for 0, 45 and 90-degree orientations.

856
 857 The last locations an installer would want to put an aero-elastic belt on are the central
 858 areas of the building’s faces (illustrated by F2 and S2). Taking into account angular
 859 averages these locations provided the least amount of power, with no power
 860 generated at all for some cases due to the wind speed not being able to make it to
 861 the aero-elastic belt’s cut-in wind speed for generation. This finding can be
 862 considered by some to be a counterintuitive result, considering these locations are
 863 directly hit by the oncoming wind.

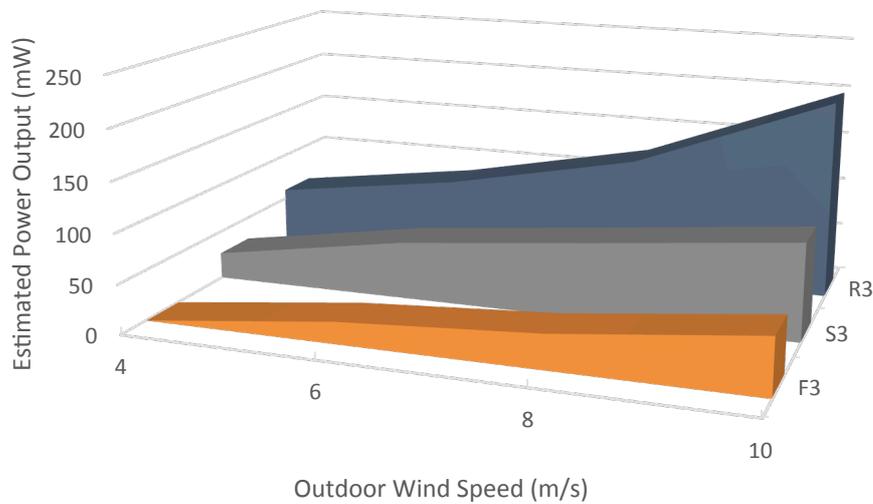

864

865 Fig. 36. Sample calculation based on aero-elastic belt (2-magnet-coil system) data
 866 measured from experimental data [6]

867

868 Figure 37 compares the estimated output of the device located in the three locations
 869 F3, S3 and R3 at various outdoor wind speeds. Among these three locations, at 30°

870 wind direction, R3 provided the highest output ranging between 59 to 200 mW, while
871 F3 showed the lowest output and only started to generate at outdoor wind velocity
872 (U_H) above 4 m/s.

873

874 Fig. 37. Impact of different outdoor wind speeds (U_H) on the estimated output of the
875 aero-elastic belt for locations F3, S3 and R3

876 5. CONCLUSIONS AND FUTURE WORKS

877

878 The aero-elastic belt is beneficial for low-energy wind harvesting in the built
879 environment due to its low cost and modularity. The necessity of investigating the
880 integration of the aero-elastic belt into buildings utilising CFD analysis is evident. The
881 review of previous works on the aero-elastic belt showed that several authors have
882 assessed the performance of the device in uniform flows in the laboratory or wind
883 tunnel but did not investigate the effect of buildings on its performance. Therefore,
884 the current work addressed the issue by carrying out CFD modelling of a simplified
885 building model integrated with aero-elastic belts. The work investigated the effect of
886 various wind speeds and aero elastic belt locations on the performance of the device.
887 The simulation used a gable-roof type building model with a 27° pitch obtained from
888 the literature. The ABL flow was utilised for the simulation of the incident wind. The
889 three-dimensional Reynolds-averaged Navier-Stokes equations jointly with the
890 momentum and continuity equations were solved through ANSYS FLUENT 16 for
891 obtaining the flow velocity field and pressure field. Sensitivity analyses for the CFD
892 grid resolutions were implemented for verification of modelling. The results of the flow
893 around the buildings and pressure coefficients were validated with previous
894 experimental work. The study utilised regression analysis and experimental data to
895 estimate the power output of the aero-elastic belt.

896

897 In terms of potential for power generation from the aero-elastic belt, the apex of the
898 roof or the highest point of the building recorded the highest power yield, with this
899 location's production being the largest with the 45-degree approach of the wind
900 relative to the building. Optimum placement of the aero-elastic belt would mean

901 prioritising the roof and the trailing edges of the building, and not the leading edge
902 nor centres of surfaces, to yield the highest possible power generation, depending on
903 wind conditions.

904
905 Subject to the prevailing wind direction within the building environment, the
906 installation location with the highest potential for energy output on the front and side
907 faces of the building can be inferred with more confidence using the results of the
908 study. With respect to the physical geometry of the frame of containing the belt, the
909 cover can be further minimised to enable more wind to flow across the belt.

910
911 There is a potential for further scaling up the system in terms of size and
912 configuration, with the plausibility of constructing an array of aero-elastic belts. The
913 results showed the importance of using detailed CFD analysis to evaluate the aero
914 elastic belt. The detailed velocity distribution results showed the capabilities of CFD
915 on assessing the optimum location of the devices around the building. The modelling
916 procedure and data presented in this work can be used by engineers/researchers to
917 further investigate the integration of the aero-elastic belt in the urban environment.

918
919 Future studies on the aero-elastic belt installation in buildings will include simulations
920 using transient models which take into account non-uniform flow conditions.
921 Prospective investigations on the impact of varying shapes of the subject building
922 and also different locations of the device will also be conducted. Further studies will
923 investigate the impact of surrounding buildings on the performance of the device as
924 well. This will incorporate the shape of surrounding buildings, distance and
925 positioning, etc. Field tests will also be carried out to evaluate device performance in
926 actual conditions and assess other factors such as noise, visual and related
927 parameters. Economic analysis of the integration of the aero-elastic belt in buildings
928 will be conducted and compared with more established low-energy generation
929 devices.

930 NOMENCLATURE

931 **Symbols**

932	U	Air velocity (m/s)
933	p	Static pressure (Pa)
934	H	Height (m)
935	L	Length (m)
936	W	Width (m)
937	x, y, z	Direction
938	g	gravitational acceleration (m/s^2)
939	S_M	Mass added to the continuous phase from the dispersed second phase
940	τ	Time in the past contributing in the integral response
941	k_{eff}	Effective conductivity (W/mk)
942	\vec{J}_j	Diffusion flux
943	S_h	Heat of chemical reaction and other volumetric heat source defined by
944	user	
945	k	Turbulence kinetic energy (m^2/s^2)
946	ϵ	Turbulence dissipation rate (m^2/s^3)

947	G_k	Generation of turbulent kinetic energy due to the mean velocity
948	gradients	
949	G_b	Generation of turbulence kinetic energy due to buoyancy
950	Y_M	Fluctuating dilatation in compressible turbulence to the overall
951		dissipation rate
952	σ_k	Turbulent Prandtl numbers for turbulence kinetic energy
953	σ_ε	Turbulent Prandtl numbers for energy dissipation rate
954	S_k	User defined source term for turbulence kinetic energy
955	S_ε	User defined source term for energy dissipation rate
956	k_s	sand-grain roughness height (m)
957	c_s	roughness constant
958	z_0	Aerodynamic roughness length (m)
959	F1, F2, F3	Front aero-elastic belts
960	S1, S2, S3	Side aero-elastic belts
961	R1, R2, R3	Roof aero-elastic belts
962	P	Power generated
963	$P_Y(t)$	Plunging contribution to the power
964	$P_\theta(t)$	Pitching contribution to the power
965	$F_Y(t)$	y-component of force
966	$V_Y(t)$	Plunging velocity
967	U_∞	Free-stream velocity
968	$M(t)$	Torque about pitching centre
969	$\omega(t)$	Angular velocity
970	C_P	Instantaneous power coefficient
971	C_{Pmean}	Time-averaged power coefficient
972	C_{Ph}	Pitching contribution to the power coefficient
973	$C_{P\theta}$	Plunging contribution to the power coefficient
974	T	Oscillation frequency
975	$C_Y(t)$	Instantaneous lift coefficient
976	$C_M(t)$	Momentum coefficient
977	η	Power-extraction efficiency
978	θ_0	Pitching amplitude
979	A	Overall vertical extent of foil motion
