## 1 2 3 4 Updated meta-review of evidence on support for carers 5 6

### 7 **Abstract** 8

9 **Objective:** To update a 2010 meta-review of systematic reviews of effective interventions to  
10 support carers of ill, disabled, or older adults. In this article, we report the most promising  
11 interventions based on the best available evidence.  
12  
13

14 **Methods:** Rapid meta-review of systematic reviews published from January 2009 to 2016.  
15  
16

17 **Results:** Sixty-one systematic reviews were included (27 high quality; 25 medium quality;  
18 and nine low quality). The quality of reviews has improved since the original review, but  
19 primary studies remain limited in quality and quantity. Fourteen high quality reviews focused  
20 on carers of people with dementia; four on carers of those with cancer; four on carers of  
21 people with stroke; three on carers of those at end of life with various conditions; and two on  
22 carers of people with mental health problems. Multicomponent interventions featured  
23 prominently, emphasising psychosocial or psychoeducational content, education and training.  
24 Improved outcomes for carers were reported for mental health, burden and stress, and  
25 wellbeing or quality of life. Negative effects were reported in the reviews following respite  
26 care. As with earlier work, we found little robust evidence on the cost-effectiveness of  
27 reviewed interventions.  
28  
29

30 **Conclusions:** There is no 'one size fits all' intervention to support carers. There is potential  
31 for effective support in specific groups of carers, such as shared learning, cognitive  
32 reframing, meditation, and computer-delivered psychosocial support for carers of people with  
33 dementia. For carers of people with cancer, effective support may include psychosocial  
34 interventions, art therapy, and counselling. Carers of people with stroke may also benefit  
35 from counselling. More good quality, theory-based, primary research is needed.

## Introduction

There is growing policy and research interest in carers, that is those who provide support, on an unpaid basis, to ill, disabled or older people in need of assistance or support with daily living. In 2009, the Department of Health in England commissioned a meta-review of the evidence base relating to the outcomes and cost-effectiveness of interventions to support unpaid carers to inform the Standing Commission on Carers, an independent advisory body providing expert advice to the UK government.<sup>1</sup>

The meta-review, published in 2010, concluded that the strongest evidence of effectiveness of interventions related to education, training and information for carers. Beyond this, there was little robust evidence about any of the interventions included in the reviewed literature, largely reflecting the mainly poor quality of underlying primary research, which was often based on small numbers, tested interventions that had no theoretical underpinning, and considered outcome measures that might have little relevance to the recipients of the interventions.<sup>1</sup>

The first legal entitlement to support for carers in the UK was incorporated into the 2014 Care Act.<sup>2</sup> Although the Act is targeted at local authorities and social care services, increased emphasis on joint commissioning and provision means that the entitlement to support also has implications for the health service. It is against this background, and the increase in published evidence since the meta-review in 2010, that an updated meta-review appears to be timely to help inform health services and future research commissioning on the needs of different types of carers and interventions to support them. In this article we summarise the findings of an updated meta-review of evidence on support for carers. We focus on the best evidence emerging from that review; the full details are available elsewhere.<sup>3</sup>

## 1 2 Methods 3 4

5 We conducted a rapid meta-review of systematic reviews focusing on non-pharmacological  
6 support interventions for carers (all ages) of ill, disabled, or older adults aged 18 years or  
7 over, including those with dementia, learning disabilities and mental health problems. We  
8 considered any outcome that related directly to carers, and interventions had to be relevant to  
9 the UK health and social care system. In the absence of a widely accepted definition of a  
10 rapid meta-review, we used an approach that involved systematic and transparent methods to  
11 appraise relevant reviews, aiming to produce a synthesis that went beyond listing key  
12 research areas and findings. This approach is less exhaustive than that of a full systematic  
13 review of reviews undertaken over a longer period. We adapted systematic review  
14 methodology to ensure we maintained high methodological standards, explicitly noting the  
15 potential limitations. In correspondence with the earlier review, we adapted (as necessary)  
16 the methods of the original meta-review,<sup>1</sup> and focused on the best evidence, as we describe  
17 below.

18 Database search strategies from the 2010 review were checked and updated (Appendix 1)

19 **[Note to Production Editor: Appendix 1 is online only]**. The searches were re-run in  
20 January 2016 on fourteen databases searched in the original meta-review. In addition,  
21 PROSPERO was searched to identify any recently completed systematic reviews. All  
22 searches were restricted to English language papers. Details of inclusion and exclusion  
23 criteria are published elsewhere.<sup>3</sup>

24 Screening of titles and abstracts was divided equally between two reviewers, with a 20%  
25 sample of retrieved abstracts divided equally between two further reviewers to double screen.  
26 Text mining software in EPPI-Reviewer 4<sup>4</sup> was used to ensure no relevant records had been  
27 missed during the single reviewer initial screening stage. Two reviewers independently made

1 final study selection decisions, with disagreements resolved by discussion or involvement of  
2 a third reviewer.  
3  
4

5  
6 We followed the approach and scoring for quality assessment used in the original meta-  
7 review, adapted from criteria developed by Egan and colleagues (2008).<sup>5</sup> Our initial searches  
8 found that there had been substantial development in the volume, content and complexity of  
9 the literature since the publication of the original meta-review in 2010. As the average quality  
10 of reviews had improved, we focused on those that would provide the most robust  
11 information. To achieve this, a number of post-protocol decisions were agreed, including the  
12 application of a second tier of quality assessment based on entry criteria for the Database of  
13 Abstracts of Reviews of Effects (DARE).<sup>6</sup> Following this, we classified reviews as 'high'  
14 'medium' or 'low' quality. 'Medium' quality reviews had to meet criteria used for the  
15 original meta-review as described above. 'High' quality reviews (using DARE criteria) had to  
16 reach a minimum score of four points comprising one each for reporting inclusion criteria,  
17 search strategy and synthesis; additionally one point for either (1) quality assessment or (2)  
18 included study details. All other reviews were classified to be 'low' quality.  
19  
20

21 We followed the approach to data extraction used in the 2010 review.<sup>1</sup> In doing so, we  
22 summarised the high quality review characteristics and recorded outcomes grouped by seven  
23 measures: physical health; mental health; burden and stress; coping; satisfaction; well-being  
24 or quality of life; ability and knowledge. We extracted basic data for the medium quality  
25 reviews. For low quality reviews, we recorded bibliographic detail only.  
26  
27

28 We adopted a pragmatic approach to the synthesis, focussing on the included high quality  
29 reviews and aiming to identify any intervention effect (positive or negative); size of effect;  
30 heterogeneity; details of the population; intervention/comparator; and outcome. We discussed  
31 review quality, highlighting the better quality primary studies and findings of interest. We  
32  
33

1 summarised the medium and low quality reviews to identify any differences regarding review  
2 coverage and characteristics of included studies.  
3  
4

5  
6 We sought views from four carers (known to us through previous work) to provide feedback  
7 on draft findings.  
8  
9

10  
11 **Results**  
12

13  
14 We initially identified 103 systematic reviews; after applying our post-protocol quality  
15 threshold, we included 61 reviews (27 high quality; 25 medium quality; nine low quality).  
16  
17

18 We first briefly summarise the overall findings of the reviews, with the full results available  
19 in the final report.<sup>3</sup> We then focus on the findings from the 27 high quality reviews. The  
20  
21 PRISMA flow chart is shown in Figure 1.  
22  
23

24 *Overview of all included reviews*  
25  
26

27 Patterns in the literature were similar to the original 2010 meta-review. While the overall  
28 quality of reviews has improved, primary study evidence remains limited in quality and  
29 quantity. Among the high quality reviews, fourteen focused on carers of people with  
30 dementia; four on carers of those with cancer; four on carers of people with stroke; three on  
31 carers of those with various conditions at the end of life; and two on carers of people with  
32 mental health problems. Many primary studies originated in the USA and Europe (including  
33 several in the UK). Where socio-demographic data were reported, carers in general were  
34 white, female and spouses or adult children of the person being supported. The age at which  
35 caregiving roles commenced ranged from early forties up to at least 70 years old.  
36  
37

38 Reviews considered a range of interventions while details of control group interventions were  
39 sparse or not reported. Multicomponent interventions featured prominently, making it  
40 difficult to identify causal relationships. Interventions generally focused on psychosocial or  
41 psychoeducational content, education and skills training. Multiple outcomes for carers were  
42  
43

1 uncovered, primarily in mental health, burden and stress, and wellbeing or quality of life. We  
2 did not observe any material differences in review topics across the high, medium and low  
3 quality reviews. As with the original work, we found little information on intervention cost-  
4 effectiveness.  
5  
6

7 There was some overlap of primary studies in the reviews we included. The effect of this  
8 overlap is difficult to judge without substantial additional analysis. There is a risk that the  
9 overlap exaggerates effects from the undue influence of individual studies, and presents  
10 difficulties in interpretation and synthesis arising from contradictory assessments of the same  
11 study.  
12  
13

14 As noted, we here draw on findings from the 27 high quality reviews.<sup>7-34</sup> Table 1 shows a  
15 subset of these reviews highlighting the most promising interventions and outcomes; this  
16 subset comprises reviews where the authors considered there to be satisfactory quality  
17 primary study evidence. Full results relating to the summary in Table 1 are shown in Table 2.  
18  
19

20 **[Table 1 about here]**  
21  
22

23 *Carers of people with dementia*  
24  
25

26 Seven of 14 high quality reviews contained satisfactory primary study quality evidence on at  
27 least one carer outcome.  
28  
29

30 Chien et al.<sup>8</sup> concluded that carers of people with dementia benefit from support groups and  
31 that the use of theoretical models to aid intervention design had a significant impact on the  
32 effect size for psychological well-being and depression. The overall quality of 30 primary  
33 studies included in this review was reported to be high or moderate. For depression, the effect  
34 size was small to moderate but with high statistical variation in the analysis of 17 studies. A  
35 small reduction in carer burden and stress was indicated in further analysis of 24 studies with  
36 low statistical heterogeneity; the effect appeared to persist over time. The quality of primary  
37 studies included in this review was reported to be high or moderate. For depression, the effect  
38 size was small to moderate but with high statistical variation in the analysis of 17 studies. A  
39 small reduction in carer burden and stress was indicated in further analysis of 24 studies with  
40 low statistical heterogeneity; the effect appeared to persist over time. The quality of primary  
41 studies included in this review was reported to be high or moderate. For depression, the effect  
42 size was small to moderate but with high statistical variation in the analysis of 17 studies. A  
43 small reduction in carer burden and stress was indicated in further analysis of 24 studies with  
44 low statistical heterogeneity; the effect appeared to persist over time. The quality of primary  
45 studies included in this review was reported to be high or moderate. For depression, the effect  
46 size was small to moderate but with high statistical variation in the analysis of 17 studies. A  
47 small reduction in carer burden and stress was indicated in further analysis of 24 studies with  
48 low statistical heterogeneity; the effect appeared to persist over time. The quality of primary  
49 studies included in this review was reported to be high or moderate. For depression, the effect  
50 size was small to moderate but with high statistical variation in the analysis of 17 studies. A  
51 small reduction in carer burden and stress was indicated in further analysis of 24 studies with  
52 low statistical heterogeneity; the effect appeared to persist over time. The quality of primary  
53 studies included in this review was reported to be high or moderate. For depression, the effect  
54 size was small to moderate but with high statistical variation in the analysis of 17 studies. A  
55 small reduction in carer burden and stress was indicated in further analysis of 24 studies with  
56 low statistical heterogeneity; the effect appeared to persist over time. The quality of primary  
57 studies included in this review was reported to be high or moderate. For depression, the effect  
58 size was small to moderate but with high statistical variation in the analysis of 17 studies. A  
59 small reduction in carer burden and stress was indicated in further analysis of 24 studies with  
60 low statistical heterogeneity; the effect appeared to persist over time. The quality of primary

1 studies was generally good, but the lack of control group data, high statistical heterogeneity  
2 for mental health outcomes, and reporting limitations in this review meant it was difficult to  
3 be totally confident about the review author's conclusions.  
4  
5

6 In a well-conducted and well-reported review of eight studies, Hurley et al.<sup>11</sup> reported  
7 tentative evidence on effectiveness of meditation-based interventions for improving scores of  
8 depression and carer burden. This conclusion was supported by primary study evidence at the  
9 end of the intervention in five moderate quality studies for depression, and in three low to  
10 moderate quality studies for carer burden. Results for both outcomes were mixed at follow-  
11 up.  
12  
13

14 In a review of seven studies looking at carer education focused on skills training, Jensen et  
15 al.<sup>12</sup> highlighted that educational programmes have a moderate effect in reducing carer  
16 burden and a small effect in reducing depression; effects were unclear for quality of life and  
17 transition to long term care. The analysis of depression included two studies (one high  
18 quality). The result for carer burden was based on five moderate quality studies with some  
19 statistical heterogeneity which favoured interventions of shorter duration. This review  
20 appeared largely well-conducted and provided additional analysis of outcomes separated by  
21 low and high income countries.  
22  
23

24 A further well-conducted Cochrane review by Lins et al.<sup>13</sup> of 11 studies observed that  
25 telephone counselling without any additional intervention can reduce depressive symptoms  
26 and also meets important needs identified by carers. The conclusion on depressive symptoms  
27 was supported in the analysis of three moderate quality studies with no evidence of statistical  
28 heterogeneity. A positive effect on depression was also found in a moderate quality study  
29 focusing on an enhanced version of the intervention comprising telephone counselling with  
30 additional video sessions and workbook. Two moderate quality, qualitative studies  
31 substantiated the review authors' conclusion on carer satisfaction with the intervention.

58  
59  
60

1 Positive control group effects for self-efficacy and satisfaction were also reported, but the  
2 quality of studies in these analyses was mixed. Theoretical underpinnings of the included  
3 studies were reported.  
4  
5

6  
7 Marim et al.<sup>14</sup>, in a well-conducted and well-reported review of seven high quality studies,  
8 concluded that interdisciplinary education and support programmes have a positive impact on  
9 carer burden when compared to standard care.  
10  
11

12 In their review of 14 studies, McKechnie et al.<sup>16</sup> found that computer-mediated psychosocial  
13 interventions can benefit carers of people with dementia. The best evidence of effectiveness  
14 related to improvements in scores for depression in the analyses of four high quality studies;  
15 for anxiety from two high quality studies; and reductions in stress and burden from five (out  
16 of nine) medium to high quality studies, with remaining studies in the latter analysis showing  
17 inconsistent results. Not all of the included studies had control groups and there were  
18 potential limitations regarding transparency of the review process.  
19  
20

21 The well-conducted Cochrane review by Vernooij-Dassen et al.<sup>19</sup> of 11 studies suggested that  
22 cognitive reframing for family carers shows promise as part of an individualised, multi-  
23 component intervention. The inclusion of cognitive reframing appeared to reduce  
24 psychological morbidity and subjective stress but without any effects on appraisals of coping  
25 or burden. In support of this conclusion, moderate to large effects were reported for reduced  
26 depression in the analysis of six studies; small effects for anxiety from the analysis of four  
27 studies; and similarly small effects were reported for stress and distress from four studies. All  
28 primary studies had some methodological limitations, but overall quality was considered by  
29 the review authors to be satisfactory.  
30  
31

1 A further review by Shoemakers et al.<sup>18</sup> of respite care for carers of people with dementia  
2 identified a negative impact on carer burden (similar to findings in the original meta-review),  
3 but this was based on unclear primary study quality and so is not included in Table 1.  
4  
5  
6  
7  
8

9 *Carers of people with cancer*  
10  
11

12 Three of four high quality reviews contained satisfactory primary study quality evidence on  
13 at least one carer outcome. Lang and Lim<sup>21</sup> reported that art therapy was effective in reducing  
14 anxiety, stress and negative emotions in family carers of patients with cancer. This  
15 conclusion reflects a statistically significant pooled effect in two studies for anxiety; effects  
16 for reduced stress from baseline in each of two studies; and an improvement in carer  
17 emotional balance in one study. This was a well reported review of moderate quality primary  
18 studies. However, findings may be limited by the reliance on two small-sized studies each  
19 with the same lead author.  
20  
21  
22  
23  
24  
25  
26  
27  
28  
29

30 Regan et al.<sup>23</sup> included six moderate to strong quality primary studies out of 23 studies  
31 overall. The authors found that couples-based psychosocial interventions showed promise,  
32 particularly in respect of improving couple communication and relationship functioning, and  
33 in reducing psychological distress. These conclusions were supported by the evidence  
34 presented. In addition, there were reductions in physical distress in one study of disease  
35 management, psychoeducation and telephone counselling; and in another study evaluating the  
36 FOCUS intervention (family coping skills and uncertainty reduction). Improvements were  
37 also noted following the FOCUS intervention for quality of life (physical and emotional  
38 functioning (two studies)).  
39

46  
47  
48  
49

50 In their review of six studies, Waldron et al.<sup>24</sup> showed that psychosocial or psychoeducation  
51 interventions focusing on problem-solving and communication skills may improve quality of  
52  
53  
54  
55  
56  
57  
58  
59  
60

1 life in carers of people with cancer. The evidence was provided by a small effect size in the  
2 analysis of two good quality studies. The review was well-conducted and reported.  
3  
4  
5  
6

7 *Carers of people with stroke*  
8  
9

10 One of four high quality reviews contained satisfactory primary study quality evidence on at  
11 least one carer outcome. Cheng et al.<sup>25, 26</sup> suggested that there was limited evidence of effect  
12 for psychosocial interventions on family functioning of carers for people with stroke. This  
13 conclusion was based on a small effect size favouring counselling over no treatment from the  
14 analysis of two moderate quality studies. In addition, satisfaction with psychoeducation,  
15 counselling or support was higher than with usual care in two moderate quality studies. This  
16 was a well-conducted review with small numbers of studies included in each analysis across  
17 multiple outcomes. Theoretical frameworks underpinning the interventions were reported.  
18  
19  
20  
21

23  
24  
25  
26  
27

28 *Carers of people with various conditions at the end of life*  
29  
30

31 No satisfactory quality primary evidence was reported in any of the three high quality  
32 reviews (not reported in Table 1).<sup>30-32</sup>  
33  
34

35 *Carers of people with mental health problems*  
36  
37

38 The original meta-review did not identify reviews that evaluated interventions for carers of  
39 people with mental health problems. In this update, we found two high quality reviews in this  
40 area,<sup>33, 34</sup> but neither reported sufficient satisfactory quality primary evidence and they are  
41 therefore not shown in Table 1.  
42  
43  
44  
45  
46  
47

55  
56  
57  
58  
59  
60

1  
2 **Discussion and conclusions**  
3  
4

5 As with the original 2010 meta-review,<sup>1</sup> reviews of interventions that might support carers of  
6 people with dementia predominated in our update. This reflects continued interest  
7 internationally in policy and practice in relation to dementia care. We also identified high  
8 quality reviews of interventions to support carers of people with mental health problems,  
9 which were absent previously. However, the quality of primary evidence in these reviews  
10 was insufficient to support any intervention effect.  
11  
12

13 Multicomponent interventions continue to dominate the evidence, with an emphasis on  
14 psychosocial or psychoeducational content. Education or training for carers and  
15 communication skills training were also evident. In terms of outcomes, the most common  
16 focus across all carer groups was on mental health, burden and stress, and wellbeing or  
17 quality of life. Reviews usually reported multiple outcomes, some of which were not clearly  
18 defined.  
19  
20

21 The findings of our meta-review indicate potential for effective support in specific groups of  
22 carers. We highlight promising interventions and outcomes from high quality reviews where  
23 satisfactory quality evidence as reported by the review authors was available from analysis of  
24 more than one study, intervention type was clearly defined, and where results of the synthesis  
25 were not mixed or inconsistent. Similar to the original meta-review, we find that the evidence  
26 on the effectiveness of respite care in supporting carers of people with dementia remains  
27 paradoxical. Carers advising on this review pointed to the usefulness of respite care as a  
28 support to them but there remains a lack of evidence of effect in empirical research. Also, as  
29 with the original work, we found little information about the cost-effectiveness of any of the  
30 interventions reviewed.  
31  
32

1 There is some evidence that interventions involving contact between carers of people with  
2 dementia and other people who know about dementia may improve some aspects of carers'  
3 mental health and of their perceptions of burden and stress. However, the evidence remains  
4 difficult to interpret, given that very different types of intervention appear to produce this  
5 effect, while we have no clear understanding of what control groups were experiencing as  
6 'usual care'. This inevitably raises the 'something better than nothing' question; that is, given  
7 the restricted social interactions some carers have, *any* contact may have beneficial effects.  
8 Alternatively, the evidence could reflect the real value of being able to share experiences with  
9 and learn from others, but this benefit does appear to be regardless of how the sharing and  
10 learning is achieved.

22  
23  
24 In relation to those caring for a person with cancer, the message seems a little clearer. Here,  
25 interventions with a psychosocial element may improve carers' physical and mental health,  
26 quality of life and relationship functioning. Art therapy, which could also be characterised as  
27 providing some psychosocial support, may also affect mental health positively. The only  
28 other group of carers for which there are any clear messages is those helping someone after a  
29 stroke. Here, counselling was shown to improve family functioning.

38 *How carers view the evidence reported here*

39  
40 We noted earlier that our review involved four carers acting as advisers who provided further  
41 insight into the evidence presented here. They highlighted that carers of people with different  
42 conditions experience different caring experiences and trajectories. From their perspective, a  
43 challenge is to know what a true 'control' carer or condition might be, thus presenting  
44 possible difficulties for a future controlled research design. They also felt that variations in  
45 caring situations and across carers made it difficult to see that a single intervention could be  
46 the 'answer' in supporting carers. This reflects our findings on the promising effect of  
47 multicomponent interventions, along with the need for evaluation of constituent parts, and  
48

59  
60

1 attention to the potential differential impact on different carers. All interventions suggesting a  
2 positive effect on carers were seen as acceptable, but advisors pointed out that what was  
3 actually available to carers was limited and incomplete. They also pointed out that standard  
4 services that were provided to the person they cared for were also of value to carers.  
5  
6

7 **Strengths and limitations**

8 Our systematic approach to this update, which is described in detail in the full report<sup>3</sup>, with  
9 clear search strategies, fully documented inclusion and exclusion criteria, decision making by  
10 more than one team member, and clearly documented data extraction and quality assessment,  
11 provides confidence that we have not missed any major sources of evidence and that our  
12 conclusions are firmly rooted in the best evidence available.  
13  
14

15 The nature of a meta-review means that it is difficult to uncover definitively what  
16 interventions work, for whom, and why. Other limitations may include the restriction to  
17 reviews published in English; the short timescale for this review (7 months), which prevented  
18 a systematic investigation of primary study overlap across the included reviews; and post-  
19 protocol decisions dictated by growth in the literature since the original meta-review.  
20  
21

22 Reviews included in this update appear to be of a higher quality overall since the original  
23 meta-review; they were generally well-conducted and reported although there were some  
24 methodological limitations. Even those reviews that we defined to be of high quality did not  
25 always assess or report the quality of included primary studies. The primary studies from the  
26 included reviews had worldwide coverage; our focus on health systems in high income  
27 countries means that results can largely be seen as relevant to the UK context.  
28  
29

30 Review authors' conclusions generally reflected the evidence they presented. However,  
31 whether due to poor quality of the primary research or to limitations of the reviews  
32 themselves, many relied on analysis of small numbers of studies, and in some cases single  
33  
34

1 studies. There was also lack of information about what support, if any, carers in control  
2 groups received, which may reflect the quality of primary studies. There is little consistency  
3 in the messages about the *type* of interventions that have been argued to have positive effects  
4 for carers, particularly for carers of people with dementia. With little understanding of the  
5 experiences of the control group, we have no way of addressing this question.  
6  
7  
8  
9  
10  
11  
12

13 The inclusion of multiple interventions in a single review, the use of multicomponent  
14 interventions in the underlying primary research, and the reported overlap of primary studies  
15 in different reviews made it difficult, in many parts of our work, to interpret cause and effect  
16 (in the few places where effect was evident).  
17  
18  
19  
20  
21  
22

23 The original meta-review highlighted the problem of intervention research that does not  
24 consider theory of change or an intervention logic to inform either the design of the  
25 intervention or the choice of appropriate outcome domains when it is evaluated. This remains  
26 an issue but, in the updated work, some review authors acknowledged this problem and, in  
27 one case, focussed exclusively on interventions where such theory was evident.<sup>19</sup> The lack of  
28 underpinning theory means that primary research often includes multiple outcome measures,  
29 none of which are identified as primary, adding further to the difficulties of ascribing cause  
30 and effect.

#### 45 **Implications for health care and research**

46 This updated meta-review identified some promising interventions for specific groups of  
47 carers, indicating improvements in mental health, burden and stress, wellbeing and quality of  
48 life. Interventions include shared learning, cognitive reframing, meditation, and computer-  
49 delivered psychosocial interventions for carers of people with dementia; psychosocial

57  
58  
59  
60

1 interventions, art therapy, and counselling for carers of people with cancer. Counselling may  
2 also help carers of people with stroke.  
3  
4

5 More good quality, theory-based, primary research is warranted. Evidence is needed on the  
6 differential impact of interventions for different types of carers, and on effectiveness of  
7 constituent parts in multicomponent programmes. Further research triangulating qualitative  
8 and quantitative evidence on respite care is urgently required. Overlap of primary studies is a  
9 problem in meta-reviews generally and warrants future methodological investigation.
