Regulation of inflammatory and anti-apoptotic responses through the IL-1RI/TILRR complex.

Eva E. Qwarnstrom
University of Sheffield, Sheffield S102RX UK

Members of the toll-like and IL-1 receptor family (TIR) are central regulators of immune and inflammatory responses. Signal activation is induced through ligand binding and controlled by system specific co-receptors.

The IL-1RI co-receptor TILRR is a splice variant of FREM-1. TILRR association with the signalling receptor magnifies IL-1-induced activation of the canonical and non-canonical NF- κ B network, by enhancing signal amplification at the level of the receptor complex and potentiate recruitment of the MyD88 adapter and PI3 kinase.

TILRR-controlled MyD88 dependent activation of the canonical pathway is regulated in a Ras-dependent manner, reflected in alterations in cytoskeletal structure and cell adhesion. The changes induced provide a process for rapid control of NF- κ B, involving sequestration and release of cytoskeletal bound I κ B α through a mechanism controlled by TILRR signal amplification. *In silico* simulations using agent based modelling of the NF- κ B network predict cytoskeletal control of inhibitor levels to provide a mechanism for signal calibration, and to enable activation-sensitive regulation of NF- κ B induced inflammatory responses.

Our studies have identified two functional sites within the TILRR core protein, which selectively control inflammatory and anti-apoptotic responses. The mechanisms underlying distinct network amplification, and the relevance of pathway-specific regulation of canonical and non-canonical NF- κ B activation will be discussed.
