Abstract: Surfactant use throughout mankind is extensive, from their initial applications as detergents extending into use in medicine, lubricant, cosmetics and even enhanced oil recovery. However, the image of surfactant use has in the past been tarnished by of issues with low biodegradability and their synthesis from non-sustainable resources. Amino acid-based surfactants are a class of surfactants derived from a hydrophobe source coupled with simple amino acids, mixed amino acids from synthesis or from protein hydrolysates, and as such can be derived solely from renewable resources. There are several pathways for their synthesis and this allows for extensive structural diversity in this class of surfactants, resulting in widespread tuneable functionality in their physiochemical properties. This review includes the details of most of the available routes of synthesis for amino acid surfactants and the impact of the diverse routes on their final physiochemical properties, including solubility, dispersability, toxicity and biodegradability. The diversity offered by the structural variation in amino acids surfactants offers many exciting commercial opportunities for this ever growing class of surfactants. It also includes a discussion on current and future potential uses of amino acid surfactants.

Abstract

Surfactant use throughout mankind is extensive, from their initial applications as detergents extending into use in medicine, lubricant, cosmetics and even enhanced oil recovery. However, the image of surfactant use has in the past been tarnished by of issues with low biodegradability and their synthesis from non-sustainable resources. Amino acid-based surfactants are a class of surfactants derived from a hydrophobe source coupled with simple amino acids, mixed amino acids from synthesis or from protein hydrolysates, and as such can be derived solely from renewable resources. There are several pathways for their synthesis and this allows for extensive structural diversity in this class of surfactants, resulting in widespread tuneable functionality in their physicochemical properties. This review includes the details of most of the available routes of synthesis for amino acid surfactants and the impact of the diverse routes on their final physicochemical properties, including solubility, dispersability, toxicity and biodegradability. The diversity offered by the structural variation in amino acids surfactants offers many exciting commercial

54

55 **1. Introduction**
56

57 Surfactants are the group of organic compounds which continue to attain great
58 interest from researchers due to their wide range of applications including as laundry
59
60
61
62
63
64
65

1
2
3
4 detergents, emulsifiers, corrosion inhibitors, oil recovery and pharmaceuticals. These are the
5
6 most representative chemical products to be consumed in major quantities daily and globally
7
8 and have in the past led to adverse effects on the aquatic environment. Many studies have
9
10 previously revealed the adverse impact of widespread use of conventional surface-active
11
12 agents on the environment (Ivanković & Hrenović, 2010). As such non-toxicity,
13
14 biodegradability and biocompatibility of surfactants have become almost equally important
15
16 for the consumers as their functional performance.
17
18
19
20

21 Biosurfactants are a class of green and sustainable surface active agents naturally
22
23 synthesized from microorganisms such as bacteria, fungi and yeast or excreted
24
25 extracellularly. Synthetic equivalents to biosurfactants can therefore be prepared by
26
27 designing molecules that imitate natural amphiphilic structures such as phospholipids,
28
29 alkylglucosides and acyl amino acids. Amino acid surfactants (AAS) are one such type of
30
31 surfactant which can generally be originated from animal or agricultural-derived feedstocks.
32
33 AAS have been gaining great interest of scientists over the last two decades as novel
34
35 surfactants as they can be synthesized using renewable sources and their ease of
36
37 degradability and harmless by-product make them safer for our environment (Kango, 2010).
38
39
40
41
42

43 AAS can be defined as a group of surfactants made up of amino acids comprising of
44
45 amino acid group ($\text{HO}_2\text{C}-\text{CHR}-\text{NH}_2$) or its residue ($\text{HO}_2\text{C}-\text{CHR}-\text{NH}_2$). These two functional
46
47 regions of amino acids give the possibility to derive an extensive range of surfactants. There
48
49 are total of 20 standard proteinogenic amino acids known in nature which are responsible
50
51 for growth and all physiological reactions of living kingdom. They differ from each other
52
53 only on the basis of the residue, R (Taubeneck, 1977) (Fig .1). Some are non-polar and
54
55 hydrophobic, others are polar and hydrophilic, some are basic and some are acidic. As
56
57
58
59
60
61
62
63
64
65

1
2
3
4 amino acids are renewable compounds, surfactants synthesized from amino acids also have
5
6 great potential as sustainable and eco-friendly substances (Infante *et al.*, 1997). Simple and
7
8 natural structure, low toxicity and fast biodegradation often make them superior over their
9
10 conventional counterparts. Their production can be via different biotechnological and
11
12 chemical routes using renewable raw materials such as amino acids and vegetable oils.
13
14

15
16 Amino acids were first discovered as a substrate for surfactants in the early 20th
17
18 century (Morán *et al.*, 2004). Primarily they were used as preservatives in pharmaceuticals
19
20 and cosmetic formulations. Furthermore, they were found to be biologically active against a
21
22 variety of disease-causing bacteria, tumors, and viruses (Husmann, 2008). In 1988
23
24 availability of amino acid surfactants at low cost increased the interest of researchers to
25
26 study their surface activity (Takehara, 1989). Nowadays, along with the growth of
27
28 biotechnology, a few amino acids are also able to be synthesized commercially at large scale
29
30 by yeasts, thus justifying their production to be more environmental friendly (Diniz Rufino
31
32 *et al.*, 2014).
33
34
35
36
37

38 **2. History**

39

40
41 The value of the structures of naturally occurring amino acids as raw materials for
42
43 preparing amphiphiles was predicted as soon as they were discovered early in the 19th
44
45 century. The first research on amino acid surfactant synthesis was reported in 1909 by
46
47 Bondi (Bondi, 1909). In this research N-acylglycine and N-acylalamine as hydrophilic
48
49 moieties of surfactants have been introduced. Subsequent work involved the synthesis of
50
51 lipo-amino acid using glycine and alanine (Gallot & Hassan, 1989). Hentrich and co-workers
52
53 published a series of findings and filed the first patent on the applications of acylsarcosinate
54
55 and acylaspartate as surfactants in household cleaning products such as shampoos,
56
57
58
59
60
61
62
63
64
65

1
2
3
4 detergents and toothpastes (Hentrich *et al.*, 1936). Subsequently the synthesis and
5
6 physicochemical properties of acyl amino acids have been studied by many researchers
7
8 (Heitmanr, 1968; Presenz, 1996). To date a significant number of research publications have
9
10 been published on the synthesis (Heitmanr, 1968; Perez *et al.*, 2009; Lundberg *et al.*, 2011;
11
12 Seguer *et al.*, 1994a; Seguer *et al.*, 1994b; Piera *et al.*, 1998; Clapes & Infante, 2002),
13
14 properties (Franklin & Snow 1981; Solans *et al.*, 1989; Kunieda *et al.*, 1992; Fördedal *et*
15
16 *al.*, 1993; Wang *et al.*, 2001; Dana *et al.*, 2011), industrial applications (Infante *et al.*, 1984;
17
18 Infante *et al.*, 1992; Infante *et al.*, 1994) and biodegradability (Piera *et al.*, 1998; Clapes *et*
19
20 *al.*, 1999; Burczyk, 2003; Trivedi *et al.*, 2011; Pinazo, 2011) of amino acid surfactants.
21
22
23
24
25

26 **3. Structural properties**

27
28 Non-polar hydrophobic fatty acid chains of amino acid surfactants may vary in their
29
30 structure, length and number. Structural variety and high surface activities of amino acid
31
32 surfactants explain their wide compositional diversity and broad range of physicochemical
33
34 and biological properties. The difference in the amino acid or peptide head group of amino
35
36 acid surfactants determines the adsorption, aggregation and biological activity of these
37
38 surfactants. Their types in terms of cationic, anionic, non-ionic and amphoteric, depends on
39
40 the functional groups present in them. The combination of hydrophilic polar amino acids
41
42 and non-polar long chain hydrophobic moiety for building up the amphiphilic structure has
43
44 created molecules with high surface activity (Infante *et al.*, 1997; Rentsch, 2002; Abdullah
45
46 *et al.*, 2009). In addition asymmetric carbons present in the molecule help in the formation
47
48 of chiral molecules (Solans *et al.*, 1990; Walther & Netscher, 1996).
49
50
51
52
53
54

55 **4. Chemistry**

56
57
58
59
60
61
62
63
64
65

1
2
3
4 All peptides and polypeptides are the polymerization product of 20 or so
5
6 proteinogenic α -amino acids. All 20 α -amino acids are comprised of a carboxylic acid ($-$
7
8 COOH) functional group and an amino ($-\text{NH}_2$) functional group attached to the same
9
10 tetrahedral α -carbon atom (Morán *et al.*, 2004). Amino acids differ from each other on the
11
12 basis of distinct R-groups attached to the α -carbon (except in the case of glycine where the
13
14 R-group is hydrogen). R groups may differ from each other in structure, size and electric
15
16 charge (acidity/basicity). These differences also determine the solubility of amino acids in
17
18 water.
19
20
21
22

23
24 Presence of 4 different substituent attached to α -carbon makes amino acids chiral in
25
26 nature (except glycine) and hence optically active. Amino acids have two possible
27
28 configurations; both are non-superimposable mirror images of each other, though in nature
29
30 the L-stereoisomers are significantly more abundant. Presence of aromatic R-groups in some
31
32 amino acids (phenylalanine, tyrosine and tryptophan) results in the absorption of ultraviolet
33
34 light with an absorbance maximum in the range of 280 nm (Solans *et al.*, 1990). Both, the
35
36 acidic α -COOH and basic α -NH₂ groups present in amino acids are able to ionize and create
37
38 ionic equilibrium as follows:
39
40
41

44
45
46
47
48 Amino acids contain at least two weakly acidic groups; however, the carboxyl group
49
50 is a far stronger acid than the amino group. At pH 7.4, the carboxyl group is unprotonated
51
52 and the amino group protonated. An amino acid with no ionizable R-group would be
53
54 electrically neutral at this pH and form zwitterions (Tamarkin *et al.*, 2014).
55
56

57 **5. Classification**

58
59
60
61
62
63
64
65

1
2
3
4 Four parameters are taken into consideration to classify amino acid surfactants, these
5
6 are sequentially addressed below:
7

8 9 **5.1 On the basis of origin**

10
11 On the basis of their origin amino acid surfactants can be categorized into two classes:
12

13 14 **5.1.1 Natural** (Pathak & Keharia, 2014; Walia & Cameotra, 2015)

15
16 Some naturally occurring amino acid containing compounds also possess the
17
18 ability to reduce surface and interfacial tension, some even surpassing the efficacy of
19
20 glycolipids. These types of amino acid surfactants are also known as lipopeptides.
21
22 Lipopeptides are low molecular weight compounds, which are generally produced by
23
24 *Bacillus* species. This class of amino acid surfactants are further classified into three
25
26 subclasses: surfactin, iturin and fengycin (Fig. 2).
27
28
29

30
31 The surfactin (Hathout *et al.*, 2000; Arima *et al.*, 1968) family covers the
32
33 heptapeptide variants of the esperin, pumilacidin, lichenysin and surfactin groups. In such
34
35 types of surfactants, the peptide moiety is linked with a C₁₂-C₁₆ unsaturated linear, iso or
36
37 anteiso β-hydroxyl fatty acid chain. Surfactins are the macrolactone rings, in which ring
38
39 closure is catalysed in between the β-hydroxyl fatty acid and the C-terminal peptide.
40
41

42
43 In the iturin (Peypoux *et al.*, 1999) subclass, there are mainly six variants i.e. iturin
44
45 A and C, mycosubtilin and bacillomycin D, F and L. In all the cases, the heptapeptide is
46
47 attached with a varied C₁₄-C₁₇ chain of β-amino fatty acids. In Iturins, because of its β-
48
49 amino nature, an amide bond is formed with the C-terminal group and thus forms
50
51 amacrolactame structure.
52
53

54
55 The Fengycins (Winkelmann *et al.*, 1983; Ongena *et al.*, 2007; Kim *et al.*, 2010)
56
57 subclass encompasses fengycins A and B, which are also known as plipastatins when Tyr⁹
58
59
60
61
62
63
64
65

1
2
3
4 is D-configured. These decapeptides are also linked with a C₁₄-C₁₈, saturated or unsaturated
5
6 linear, iso or anteiso-β-hydroxyl fatty acid chain. Structurally, fengycins are also a
7
8 macrolactone ring that includes a Tyr side chain at third position in the peptide sequence
9
10 and form an ester bond with the C-terminal residue, thus form an internal ring like structure
11
12
13 in many *Pseudomonas* lipopeptides.
14

15 16 **5.1.2 Synthetic (Xia, 2001)** 17

18
19 Amino acid surfactants can also be synthesized experimentally by use of any of the
20
21 acidic, basic and neutral amino acids. Common amino acids used for their synthesis are
22
23 glutamic acid, serine, proline, aspartic acid, glucine, arginine, alanine, leucine and protein
24
25 hydrosylates. Surfactants of this subclass can be prepared chemically, enzymatically and
26
27 chemoenzymatically however, chemical synthesis has been found more economically
28
29 feasible for their production. Common examples of this include N-lauroyl-L-glutamic acid,
30
31 N-palmitoyl-L-glutamic acid.
32
33
34

35 36 **5.2. On the basis of the substitution of aliphatic chain** 37

38
39 On the basis of the substitution of aliphatic chain amino acid based surfactants can
40
41 be classified into two types (Clapes & Infante, 2002):
42

43 **5.2.1. On the basis of substitution site** 44

45
46 In this type, there are three different categories:
47

48 **5.2.1.1. N-substituted amino acid surfactants** 49

50
51 In N-substituted compounds an amino group is substituted either with a lipophilic
52
53 moiety or a carboxylic group, resulting in the loss of alkalinity. The simplest examples of N-
54
55 substituted amino acid surfactants are N-acyl amino acids, which are anionic in nature. N-
56
57 substituted amino acid surfactants have an amide linkage formed in between the
58
59
60
61
62
63
64
65

1
2
3
4 hydrophobic moiety and the hydrophilic moiety. The ability of amide linkage to form
5
6 hydrogen bond eases the degradation of such surfactants under acidic environment and
7
8 hence makes them biodegradable.
9

10 11 **5.2.1.2. C-substituted amino acid surfactants**

12
13
14 In C-substituted compounds substitution takes place on the carboxylic group through
15
16 an amide or an ester bond. C-substituted compounds are typically cationic in nature such as
17
18 esters or amides.
19

20 21 **5.2.1.3. N- and C- substituted amino acid surfactants**

22
23
24 In second type of the surfactants, both the amino and the carboxylic groups are
25
26 present as part of the hydrophilic moiety. These types are amphoteric in nature.
27

28 29 **5.3 On the basis of number of hydrophobic tail**

30
31 On the basis of number of hydrophobic tail and head groups, amino acid surfactants
32
33 are classified into four groups (Moran *et al.*, 2004). Single or linear chain amino acid
34
35 surfactants, dimeric or gemini amino acid surfactants, glycerolipids type amino acid
36
37 surfactants and bolaamphiphiles amino acid surfactants. Linear chain surfactants are the
38
39 surfactants, comprised of amino acids with the minimum one hydrophobic tail (Fig. 3).
40
41 Dimeric amino acid surfactants have two amino acids polar head group and two
42
43 hydrophobic tails per molecule (Fig. 4). In this class, two linear amino acids surfactants are
44
45 joined together via spacer and hence also called dimerics. Glycerolipids type amino acid
46
47 surfactants contain two hydrophobic tails attached to a one common amino acid head group
48
49 (Fig.5). These surfactants can be considered as an analogue of monoglycerides, diglycerides
50
51 and phospholipids. Bolaamphiphiles amino acid surfactants are a group of surfactants that
52
53 has two polar amino acid heads that are joined together via single hydrophobic tails (Fig. 6).
54
55
56
57
58
59
60
61
62
63
64
65

1
2
3
4 **5.4. On the basis of head group type**
5

6 On the basis of polar head group amino acid based surfactants are further classified
7 into cationic, anionic, zwitterionic and non-ionic amino acid surfactants.
8
9

10
11 **5.4.1 Cationic**
12

13
14 In this class of surfactants, the head group bears positive charge. The first
15 commercially available cationic amino acid surfactant is cocoyl arginine ethyl ester (CAE)
16 as a PCA (pyrrolidone carboxylic acid) salt. This surfactant has unique and varied properties
17 that make it useful in disinfectants, antimicrobial agents, antistatic agents, hair conditioner
18 and it is also very mild to eyes and skin and easily biodegradable (Xia., 2001). Singare &
19 Mhatre, 2012 have synthesized arginine based cationic amino acid surfactants and evaluated
20 them on the basis of their physicochemical properties. In this study, they claimed the good
21 yield of product using Schotten Baumann reaction conditions. Increase in the surface
22 activity and decrease in the critical micelle concentration (CMC) of surfactants was found
23 with the increase in alkyl chain length and the hydrophobicity. Quaternary acyl protein is
24 another known example of this class which is generally used as conditioner in hair care
25 products (Kim *et al.*, 2010).

43 **5.4.2. Anionic**
44

45 In anionic surfactants, negative charge is present on the polar head group of
46 surfactants. Sarcosinate surfactants are an example of anionic amino acid surfactants.
47 Sarcosine ($\text{CH}_3\text{-NH-CH}_2\text{-COOH}$, *N*-methyl glycine) is an amino acid normally found in sea
48 urchins and starfish and is chemically related to glycine ($\text{NH}_2\text{-CH}_2\text{-COOH}$), a basic amino
49 acid found in the cells of mammals. Lauric acid, myristic acid and oleic acid and their
50 halides and esters are generally used to synthesize sarcosinate surfactants. Sarcosinate are

3
4 mild in nature, due to which they are generally used in mouthwashes, shampoos, aerosol
5
6 shaving lathers, sunscreens, skin cleansers and other cosmetics (Castillo *et al.*, 2001).
7
8

9 Other commercial anionic amino acid surfactants include Amisoft CS-22 and
10 Amilite GCK-12, which are the trade names of Sodium N-Cocoyl-L-Glutamate and
11 Potassium N-Cocoylglycinate, respectively. Amilite is generally used as foaming agent,
12
13 detergent, solubilizer, emulsifier and as a dispersing agent and has numerous applications in
14 cosmetics as shampoo and bath soap, body wash, toothpaste, face wash, facial soap, contact
15 lens cleaners and household tensides (Aubert & Dussault, 2008). Amisoft is used as a mild
16 skin and hair cleansers and predominantly used in face and body cleansers, synthetic
17
18 detergent bars, body care hair shampoos and other skin care products (Castillo *et al.*, 2000).

26
27

28 **5.4.3. Zwitterionic (Amphoteric)**

29
30
31 Amphoteric surfactants contain both acidic and basic sites and thus change charge by
32
33 varying pH. They behave like anionics in alkaline medium, behave as cationics in acidic
34 environment and amphoteric in neutral medium. Lauroyl lysine (LL) and Alkoxy (2-
35 hydroxypropyl) arginine are the only known amino acid based amphoteric surfactants. LL is a
36 condensation product of lysine and lauric acid. Due to its amphoteric structure, LL is
37 insoluble in almost all type of solvents except highly alkaline or acidic solvents. Excellent
38 adhesive property towards hydrophilic surfaces and low friction coefficient of LL as organic
39 powder imparts excellent lubricating ability in this surfactant. LL is widely used in skin
40
41 creams and hair conditioners or as a lubricant (Mohr *et al.*, 2000).

50
51

52 **5.4.4. Nonionic**

53
54
55 Nonionic surfactants are characterized with polar head groups that carry no formal
56
57 charge. Sabagh and his co-workers prepared eight novel ethoxylated nonionic surfactants
58
59

3
4 using oil soluble α -amino acids. In this process, esterification of L-phenylalanine and L-
5 leucine followed by amidation with cetyl alcohol and palmitic acid, respectively yielded
6
7 two amides and two esters of α -amino acids. The ethylene oxide was then condensed with
8
9 the amides and esters prepared and produced three different polyethylene oxide units of 40,
10
11 60, and 100 as phenylalanine derivatives. These nonionic type amino acid surfactants were
12
13 found to have good detergency and foaming properties (Sabagh *et al.*, 2009).

15
16
17
18

19 **6. Synthesis**

20 **6.1 Fundamental synthesis paths**

21
22 In amino acid surfactants, the hydrophobic group may be attached either at the amine
23
24 moiety, the carboxylic acid moiety, or through the side chain of the amino acid. On the basis
25
26 of this approach, four fundamental synthesis paths are available to researchers (Kimura *et*
27
28 *al.*, 1992) as given in figure 7.
29
30
31

32
33 **Path 1** shows the production of amphiphilic esteramine through esterification
34
35 reactions, in which surfactants synthesis is typically achieved by refluxing fatty alcohols and
36
37 amino acid in the presence of dehydrating agent and acidic catalyst. In some reactions
38
39 sulphuric acid plays the role of both catalyst and dehydrating agent.
40
41
42

43 **Path 2** shows the synthesis of amphiphilic amidoamine by creating the amide bond
44
45 through the reaction of an activated amino acid and alkyl amine to create the desired amide
46
47 bond.
48
49

50 **Path 3** shows the production of amidoacid through the reaction of amine group of
51
52 amino acid with fatty acid.
53
54

55 **Path 4** shows the synthesis of long chain alkyl amino acids via the reaction of amine
56
57 group with alkyl halogen.
58
59

65

1
2
3
4 **Path 5** involves the coupling of the specific function of the side group of the amino
5
6 acid. In this type of path, generally carboxylic group of aspartic acid and glutamic acid react
7
8 with fatty alcohol to form anhydride (Fig.8).
9

10 11 **6.2. Development in the synthesis/production**

12 13 **6.2.1. Synthesis of single-chain amino acid/peptide surfactants**

14
15 Synthesis of N-Acyl and O-acyl amino acids (Kimura *et al.*, 1992) or peptides can be
16
17 achieved by the enzyme-catalysed acylation reaction of amine or alcohol groups with fatty
18
19 acids. The first description of solvent-free lipase catalyzed synthesis of amino acid amide or
20
21 methyl ester derivatives was reported by using *Candida antarctica* with the yield in the
22
23 range of 25-90% depending on the target amino acid (Godtfredsen and Bjoerkling, 1990).In
24
25 some reactions, ethylmethyl ketone has also been used as solvent. Vonderhagen *et al.*, 1999
26
27 also illustrated the lipase and proteases catalyzed N-acylation of amino acids, protein
28
29 hydrolysates and/or their derivatives using the mixture of water with organic solvents such
30
31 as dimethylformamide/water and butylmethylketone. In these earlier examples, the major
32
33 issue with enzymatic synthesis of amino acid surfactants was typically very low yields.
34
35 Valivety *et al.*, 1997 reported yields of just 2– 10% of N-myristoyl amino acid derivatives
36
37 even after many days under incubation at 70°C by using different lipases. Problems
38
39 associated with the low yields of amino acid were also supported by Montet and his co-
40
41 workers (Montet *et al.*, 1990) during the synthesis of N-acyllysines using fatty acids and
42
43 vegetable oils. They reported a maximum 19% yield of the product under both the solvent-
44
45 free conditions as well as under organic solvents. Valivety *et al.*, 1998 also supported the
46
47 same issue while synthesizing N-Cbz-L-Lysine or N-Cbz- Lysine methyl ester derivatives.
48
49 In this study, they claimed 80 % yield of 3-O-myristoyl-L-serineusing N-protected serine as
50

3
4 substrate and Novozyme 435 as catalyst under melted solvent free environment. Nagao and
5
6 Kito studied the results of O-acylation of L-serine, L-homoserine, L-threonine and L-
7
8 tyrosine using lipases obtained by *Candida cylindracea* and *Rhizopusdelemar* in aqueous
9
10 buffered medium and reported the acylation of L-homoserine and L-serine upto some extent
11
12 with low yield whereas no acylation takes place on L-threonine and L-tyrosine (Nagao &
13
14 Kito, 1989). Various researchers supported the use of cheap and easily available substrate to
15
16 synthesize cost effective amino acid surfactants. Soo'sresearch group claimed the best
17
18 results of palm oil based surfactants using immobilized lipoenzyme. In this investigation
19
20 they stated that although reactions with palm oil fractions required long reaction duration of
21
22 6 days but resulted better yields of products (Soo *et al.*, 2003). Gerova and his co-workers
23
24 studied the synthesis and surface active properties of several optically active and racemic
25
26 mixtures chiral of *N*-palmitoyl amino acid surfactants based on methionine, proline, leucine,
27
28 threonine, phenylalanine and phenylglycine (Gerova *et al.*, 2008). Pang & Chu, 2010
29
30 described theco-polycondensation of amino acid based monomers and dicarboxylic acid
31
32 based monomers to synthesize a series of biodegradable functional amino acid-based
33
34 polyesteramides in solution.

7
8

9 **6.2.2. Synthesis of gemini amino acid/peptide surfactants**

10
11 Amino acid based gemini surfactants are comprised of two linear amino acid
12
13 surfactants molecules joined together head to head via a spacer (Yoshimura *et al.*, 2012).
14
15 Two possible Schemes have been derived for the chemo-enzymatic synthesis of gemini
16
17 types amino acid based surfactants (Schemes1, 2). In the first Scheme, two amino acid
18
19 derivatives react with the spacer followed by the introduction of the two hydrophobic
20
21 groups. In the second Scheme, the two linear structures are joined directly through
22
23 bifunctional spacer chain (Piera *et al.*, 2000). Valivety and his co-workers (Valivety *et al.*,
24
25 1997) were the first to develop the enzymatic synthesis of gemini lipoamino acids.
26
27 Yoshimura and his co-worker (Yoshimura *et al.*, 2012) studied the synthesis, adsorption,
28
29 and aggregation properties of an amino acid-based gemini surfactant based on cystine and n-
30
31 alkyl bromide. Comparisons of the synthesized surfactants have also been performed against
32
33 their corresponding monomeric counterparts. Faustino *et al.*, 2009 described the synthesis
34
35 of anionic urea-based monomeric amino acid surfactants and their corresponding geminis
36
37 based on L-cystine, D-cystine and DL cystine, as well as derived from L-cysteine, L-
38
39 methionine and L-cysteic acid and their characterization was achieved in terms of electrical
40
41 conductivity, equilibrium surface tension, and steady-state fluorescence spectroscopy
42
43 techniques. Comparison studies between monomeric forms and geminis stated that geminis
44
45 have lower critical micelle concentration (CMC) values.

53

54 **6.2.3. Synthesis of glycerolipidamino acid/peptide surfactants**

55
56
57
58
59
60
61
62
63
64
65

1
2
3
4 Glycerolipidamino acid/peptide surfactants comprises of a novel class of lipoamino
5
6 acids, which are the structural analogues of mono-diacylglycerides and phospholipids as one
7
8 or two aliphatic chains and one amino acid joined together via ester bonds in the glycerol
9
10 backbone. Synthesis of such types of surfactants starts with the preparation of glyceryl
11
12 esters of amino acid in the presence of an acid catalyst such as BF₃ at elevated temperatures
13
14 (Valivety *et al.*, 1997). Enzymatic synthesis using hydrolases, proteases and lipases as
15
16 catalyst was also found to be good alternative (Scheme 3) (Mitin *et al.*, 1997). Enzymatic
17
18 synthesis of dilauroylated arginine glyceride conjugate with papain enzyme has also been
19
20 reported. Synthesis of diacylglycerolipid conjugates from acetyl-arginine and evaluation of
21
22 their physicochemical properties have also been reported (Moran *et al.*, 2001; Perez *et al.*,
23
24 2004).

30 31 **6.2.4. Synthesis of bolaamphiphiles amino acid/peptide surfactants**

32
33 Amino acid-based bolaamphiphiles contain two amino acids connected with a
34
35 hydrophobic linker. Franceschi *et a.*, 1999 described the synthesis of bolaamphiphiles with
36
37 two amino acids (D- or L-alanine or L-histidine) and an alkyl chain of varying length and
38
39 studied their surface active properties. In this research work, they discussed the synthesis
40
41 and aggregation of novel bolaamphiphiles bearing amino acid moieties using unusual β -
42
43 amino acids or an alcohol and spacers with C₁₂-C₂₀. The unusual β -amino acids used may be
44
45 sugar amino acid, an AZT-derived amino acid, a norbornene amino acid, and an AZT-
46
47 derived amino alcohol (Scheme 4). Polidori *et al.*, 2006 has also given synthesis of
48
49 symmetric bolaamphiphiles derived from tris (hydroxymethyl) aminomethane (Tris)
50
51 (Scheme 4).

7. Physiochemical Properties

Amino acid based surfactants are known to have wide range of desirable properties that increase their applicability in varied applications such as good solubilization, good emulsifying properties, high efficiency, high surface activity and good lime resistance (calcium tolerance).

A variety of surface active properties of amino acids based surfactants like surface tension, CMC, phase behaviour and Krafft temperature have been studied by many scientists and it was concluded that amino acid surfactants have superior surface activity than their conventional counterparts. Properties of amino acid surfactants are discussed below:

7.1. Critical micelle concentration (CMC)

Critical micelle concentration (CMC) is an important phenomenon of surfactants as it governs a number of surface active properties such as solubilization, lytic action and their interaction with biological membranes etc. Commonly, increasing in the chain length of hydrocarbon tail (increasing hydrophobicity), resulted in decreased CMC values of surfactant solution and hence increased their surface activity (Mukerjee & Mysels, 1971). When compared to conventional surfactants, amino acid based surfactants generally have lower CMC values (Perez *et al.*, 2004).

Infante *et al.*, 1984 synthesized three arginine based amino acid surfactants by varying the combination of head group and hydrophobic tail (mono cationic amide, dicationic amide and di cationic amido-ester) and studied their CMC and gamma CMC values (surface tension at the CMC and the results showed a decrease in CMC and Gamma CMC values by increasing the length of hydrophobic tail. In a different study Mhatre & Singare, 2012 also

1
2
3
4 confirmed the CMC decreases with an increase in the number of carbon atoms in
5
6 hydrophobic tail of N α -acyl arginine surfactants [Table1].
7
8

9 Yoshimura *et.al.*, 2012 investigated the CMC values of amino acid based gemini
10
11 surfactants derived from cysteine and showed the decreasing pattern in CMC values by
12
13 increasing the carbon length from 10 to 12 within the hydrophobic chain. Further increases
14
15 in the carbon chain length upto 14 resulted in an increase in CMC values, confirming the
16
17 low aggregation tendency of gemini surfactants.
18
19

20
21 Faustino *et al.*, 2011 reported the formation of mixed micelles in aqueous solutions
22
23 of cystine based anionic gemini surfactants. The comparison has also been made with the
24
25 gemini surfactant with its conventional monomeric counterpart, C₈Cys. CMC values for
26
27 lipid-surfactant mixtures were reported to be lower than that of pure surfactant. The gemini
28
29 surfactant and 1,2-diheptanoyl-sn-glycero-3-phosphocholine, a water-soluble, micelle-
30
31 forming phospholipid was shown to have CMC values in the milimolar range.
32
33

34
35 Shrestha & Aramaki, 2009 studied the visco-elastic wormlike micelles formation in
36
37 the aqueous systems of mixed type amino acid-based anionic and non-ionic surfactants in
38
39 the absence of salt. In this investigation, N-dodecylglutamic acid was found to have higher
40
41 Krafft temperature; however, when neutralized with alkaline amino acid L-lysine, it
42
43 generated the micelles and the solution started behaving like a Newtonian fluid at 25°C.
44
45
46

47 48 **7.2. Good water solubility** 49

50 Good water solubility of amino acid surfactants is due to presence of additional CO-
51
52 NH linkage (Moran *et al.*, 2004).This ability makes them readily biodegradable and
53
54 environmentally friendly in comparison to their conventional counterparts. The presence of
55
56 two carboxylic groups leads to even better solubility of N-acyl-L-glutamic acid in
57
58
59
60
61
62
63
64
65

1
2
3
4 water.Presence of two ionic arginine groups in one molecule of $C_n(CA)_2$ also exhibits good
5
6 water solubility thus resulting in more effective adsorption and diffusion on the cell
7
8 interface and showing effective antimicrobial action even at lower concentrations.
9

10 11 **7.3 Krafft temperature and Krafft point**

12
13
14 Krafft temperature can be understood as the unusual solubility behaviour of surfactants and
15
16 rapid increase in their solubilities above specific temperature (Pilemand, 2002). Ionic
17
18 surfactants have the affinity to produce solid hydrates through precipitation from the
19
20 aqueous medium. The solubility of the surfactants will commonly be observed to undergo a
21
22 sharp and discontinuous increase at some distinctive temperature, which is referred to as the
23
24 Krafft temperature. Krafft point of ionic surfactants is the Krafft temperature at their critical
25
26 micelle concentration (Malik & Ali, 2016).
27
28
29

30
31 This solubility characteristic is generally observed in ionic type surfactants and can
32
33 be explained on the basis of limited solubility of non-associated surfactants below Krafft
34
35 temperature and the solubility increasing gradually until the Krafft point is reached, which
36
37 was due to micelle formation. To achieve complete solubility it is necessary to prepare
38
39 surfactant formulations above their Krafft point (Puerto, 2001).
40
41
42

43
44 Krafft temperature of amino acids surfactants have been studied by various
45
46 researchers and comparison were made with the Krafft temperature of conventional
47
48 synthetic surfactants. Shrestha et. al., 2009 studied the Krafft temperature of arginine based
49
50 amino acid surfactants which were found to exhibit premicellar aggregation CMC values
51
52 above $2-5 \times 10^{-6}$ M followed by the normal micellization at $3-6 \times 10^{-4}$. Ohta *et al.*, 2003
53
54 synthesized six different types of N-hexadecanoyl amino acid surfactants, and discussed
55
56 their relationship between the Krafft temperature and the amino acid residue.
57
58
59
60
61
62
63
64
65

1
2
3
4 In an experiment, an increase in the Krafft temperature of N-hexadecanoyl amino
5 acid surfactant was found with decrease in the size of the amino acid residue (phenylalanine
6 is an exceptional case). Whereas, an increase in the enthalpy of solution was found
7 endothermic with decrease in the size of the amino acid residue (except for glycine and
8 phenylalanine). From these observations it was concluded that D-L interaction was superior
9 to the L-L interaction in solid state of N-hexadecanoyl amino acid surfactant salt in both the
10 alanine system and the phenylalanine system.
11
12
13
14
15
16
17
18
19
20

21 Brito *et al.*, 2011 also determined the Krafft temperatures of three series of novel
22 amino acid based surfactants using differential scanning micro calorimetry and found the
23 change from trifluoroacetate ion to iodide which causes a relative large increase ($\approx 6^\circ\text{C}$) in
24 Krafft temperature from 47 to 53 $^\circ\text{C}$. Presence of a cis-double bond and unsaturation present
25 in long chain Ser-derivative significantly decreases the Krafft temperature. N-
26 Dodecylglutamic acid was reported to have higher Krafft temperature. However,
27 neutralization with alkaline amino acid L-lysine resulted in micelles formation in the
28 solution which behaves like a Newtonian fluid at 25 $^\circ\text{C}$.
29
30
31
32
33
34
35
36
37
38
39
40

41 **7.4. Surface tension**

42
43 Surface tension of surfactants increased with increasing chain length of the
44 hydrophobic moiety. Zhang *et al.*, 2013 determined the surface tension values of sodium
45 cocoylglycinate by Wilhelmy plate method using a DCAT11 tensiometer at 25 $^\circ\text{C} \pm 0.2^\circ\text{C}$
46 and obtained surface tension values of 33 $\text{mN}\cdot\text{m}^{-1}$ at the CMC of 0.21 $\text{mmol}\cdot\text{L}^{-1}$. Yoshimura

2
3
4 length up to $n=8$, whereas the trend reversed for surfactants with $n=12$ or longer chain
5
6 lengths.
7

8
9 The effect of CaCl_2 on surface tension of dicarboxylic amino acids type surfactants
10 has also been studied (Bordes *et al.*, 2009). In this investigation addition of CaCl_2 in
11 aqueous solutions of three dicarboxylic amino acid-based surfactants ($\text{C}_{12}\text{MalNa}_2$,
12 $\text{C}_{12}\text{AspNa}_2$ and $\text{C}_{12}\text{GluNa}_2$) was carried out. Surface tensions were found to be lower at very
13
14 low CaCl_2 compared compared to that at the plateau value beyond the CMC. This was due
15
16 to the effect of calcium ions on the packing of the anionic surfactants at the air-water
17
18 interface. Surface tension of the salts of N-dodecyl aminomalonic acid and N-dodecyl
19
20 aspartic acid remained almost constant up to a 10 mM concentration of CaCl_2 . Above 10
21
22 mM a rapid increase in surface tension was observed, which was due to the formation of
23
24 calcium salt precipitate of the surfactant. In case of disodium salt of N-dodecylglutamic
25
26 acid, a considerable decrease in surface tension was observed by moderate addition of CaCl_2
27
28 that remained almost constant over a broad range of CaCl_2 concentrations.
29
30
31
32
33
34
35
36
37

38 For the determination of adsorption kinetics at air/water interface for gemini amino
39 acid surfactants, dynamic surface tension measurements were carried out via the maximum
40
41 bubble pressure method. Results revealed no change in the dynamic surface tension for
42
43 $2\text{C}_{12}\text{Cys}$ for the longest measurement time. Reduction in the dynamic surface tension only
44
45 depends on the length of hydrocarbon tail, number of hydrocarbon tails and the
46
47 concentration. Faster decay was observed by increasing the concentration and decreasing the
48
49 chain length and chain numbers of the surfactants. Results obtained at higher concentrations
50
51 of C_nCys ($n=8-12$) were found very close to the γ_{cmc} obtained through Wilhelmy surface
52
53 tension.

2
3
4 In other research (Fan *et al.*, 2008) the dynamic surface tension of SDLC (sodium
5 dilauroylcystine) and SDDC (sodium didecaminocystine) was determined using Khan DCA-
6
7
8
9 315 tensiometer through Wilhelmy plate technique and the equilibrium surface tension of
10
11 their aqueous solution was measured by drop volume method. Further studies on the
12
13 reaction of the disulfide bond were also performed by other methods. Addition of
14
15 mercaptoethanol to 0.1 mmol L⁻¹ SDLC solution resulted in the rapid increase in surface
16
17 tension from 34 to 53 mNm⁻¹. As NaClO can oxidize the disulfide groups of SDLC to
18
19 sulfonic groups, when NaClO (5 mmol L⁻¹) was added into 0.1 mM L⁻¹SDLC solution.
20
21
22
23
24 Transmission Electron Microscopy (TEM) and Differential Light Scattering (DLS) results
25
26 showed no aggregate formation in the solution. The surface tension of SDLC was found to
27
28 increase from 34 to 60 mNm⁻¹ over the duration of 20 min.
29
30

31 **7.5 Binary surface interaction**

32
33 The vibrant properties of the mixture of cationic type amino acid surfactants (diacyl-
34
35 glycerol-arginine based surfactant) with phospholipids at the air-water interface for life
36
37 sciences have been reported by many research groups and it was finally concluded this non-
38
39 ideal characteristic as an asset to the pervasiveness of electrostatic interactions (Hines *et al.*,
40
41 1997; Wu *et al.*, 2017).
42
43
44

45 **7.6. Aggregation properties**

46
47 DLS measurements are commonly used to determine the aggregation properties of
48
49 amino acid based monomeric and gemini surfactants, at concentrations higher than the CMC
50
51 and the diffusion coefficient so obtained is converted into the apparent hydrodynamic
52
53 diameter $D_H (=2R_H)$. When compared to the other surfactants, C_nCys and $2C_nCys$ formed
54
55 relatively large aggregates with a wide size distribution. Surfactants other than $2C_{12}Cys$
56
57
58
59
60
61
62
63
64
65

1
2
3
4 generally form aggregates of about 10 nm. The micelle size for gemini surfactants was
5
6 found significantly larger than their monomeric counterparts (Faustino *et al.*, 2009).
7
8 Increase in the hydrocarbon chain length also results in the increase micellular size (Brito *et*
9
10 *al.*, 2009). Ohta *et al.*, 2007 described the aggregation properties of aqueous solutions of
11
12 three different stereoisomers of tetramethyl ammonium N- dodecyl phenyl alanyl phenyl
13
14 alaninate and revealed that the diastereomers have same critical aggregation concentrations
15
16 in aqueous solutions. Iwahashi *et al.*, 2009 investigated the formation of chiral aggregates of
17
18 optically active N-lauroyl-L-glutamic acid (L-LGA), N-lauroyl-L-valine (L-LVA) and its
19
20 methyl ester in different solvents like tetrahydrofuran, acetonitrile, 1,4-dioxane and 1,2-
21
22 dichloroethane through measurement of circular dichroism (CD), NMR chemical shift of N-
23
24 H proton and vapour pressure osmometry.
25
26
27
28
29

30 31 **7.7. Interfacial adsorption**

32
33 Amino acids based surfactants have also been characterized in terms of their
34
35 interfacial adsorption and compared to their conventional counterparts. Dodecyl ester of
36
37 aromatic amino acids obtained from l-tyrosine (LET) and l-phenylalanine (LEP) were
38
39 subjected to assess their interfacial adsorption characteristics (Vijay *et al.*, 2008). Results
40
41 revealed that LET and LEP exhibit lower interfacial area at the air/solution and in
42
43 water/hexane interface, respectively.
44
45
46

47
48 Bordes *et al.*, 2009 investigated the solution behaviour and adsorption of three
49
50 dicarboxylic amino acid-based surfactants, the disodium salts of dodecylglutamic acid,
51
52 dodecylaspartic acid and dodecylaminomalonic acid with three, two and one carbon atoms,
53
54 respectively between the carboxyl groups at the air–water interface. It was reported that
55
56 CMC of dicarboxylic surfactants was 4-5 times higher than mono carboxyl group containing
57
58
59
60
61
62
63
64
65

1
2
3
4 dodecylglycinate. This was attributed to the presence of hydrogen bonding between adjacent
5
6 molecules through the amide groups in the dicarboxylic surfactants.
7
8

9 **7.8. Phase behaviour**

10
11 Phase behaviour of the surfactants can be determined using sealed ampoules
12
13 containing requisite quantities of reagents which were mixed at higher temperatures and get
14
15 homogenized with a vortex mixer through repeated centrifugation. After mixing properly,
16
17 the samples are kept in a thermostatically controlled water bath at 25°C for a few days to
18
19 ensure equilibrium. The equilibrated phases were acknowledged by visual observations
20
21 using normal and crossed polarizer. At high concentration of surfactant, the isotropic
22
23 discontinuous cubic phase was observed. A large hydrophilic head group of the surfactant
24
25 molecule favoured the small and discrete aggregates of positive curvature (Johnsson &
26
27 Edwards, 2001). Marques *et al.*, 2008 studied the phase behaviour of 12 Lys12/12 and 8
28
29 Lys8/16 Sersystems and stated that the 12 Lys12/12 Sersystem has phase separation
30
31 between the micellar and vesicle solution. Small micelles were found to coexist in between
32
33 the vesicles in the former whereas 8 Lys8/16 Sersystems showed a continuous transition
34
35 process (where the elongated micelles were found to be present in between the small
36
37 micelles and vesicles).
38
39
40
41
42
43
44

45 **7.9. Emulsification**

46
47 Kouchi *et al.*, 2001 examined the emulsification potency of N-[3-lauryl-2-
48
49 hydroxypropyl]-L-arginine, L-glutamate, along with other amino acid surfactants, in terms
50
51 of interfacial tension, dispersability and viscosity. Comparison of synthesized surfactants
52
53 has also been made with their conventional non-ionic and amphoteric counterparts and
54
55
56
57
58
59
60
61
62
63
64
65

1
2
3
4 results revealed that the amino acid surfactants have greater emulsification potency than
5
6 conventional surfactants.
7

8
9 Baczko *et al.*, 2004 synthesized novel amino acid-based anionic surfactants and
10 investigated their usability as chiral oriented NMR spectroscopy solvents. A series of
11 sulfonated amphiphilic L-Phe or L-Ala derivatives with pentyl to tetradecyl tails were
12 synthesized by reacting the corresponding amino acid esters with o-sulfobenzoic anhydride.
13
14 Wu *et al.*, 2014 synthesized SFAAA (sodium N-fatty acyl amino acid) surfactant using pupa
15 oil and obtained PPH (pupa protein hydrolysates) as a waste by-product of the silk industry.
16
17 Studies on the emulsifying power of PPH and SFAAA in an oil/water emulsion revealed
18 that these surfactants were found superior with ethyl acetate as the oil phase over n-hexane.
19
20
21
22
23
24
25
26
27

28 **7.10. Lime tolerance**

29
30
31 Lime tolerance can be understood as the resistance of surfactant to precipitate as lime
32 soap in the presence of calcium, magnesium like ions present in hard water. Surfactants with
33 high tolerance against water hardness were found useful for detergent formulations and
34 personal care products. Determination of the lime tolerance can be achieved by calculating
35 the solubility and the surface activity change of surfactants in the presence of calcium ions
36 (Bordes *et al.*, 2009). Another method used to determine lime tolerance involve the
37 calculation of percentage or the number of grams of surfactant required for the dispersion of
38 lime soap formed from 100 g sodium oleate in water (Holmberg *et al.*, 2004). In hard water
39 areas, high concentrations of calcium and magnesium ions and mineral content can lead to
40 difficulties in some practical applications. Sodium ions are generally used as the counter
41 ions in the synthesis of anionic surfactants. By virtue of being bivalent calcium ions bind to
42 two surfactant molecules resulting in the easier surfactant precipitation from solution and
43
44
45
46
47
48
49
50
51
52
53
54

56
57
58
59
60
61
62
63
64
65

1
2
3
4 thus reducing detergency. Studies on lime tolerance of amino acid surfactants showed that
5
6 'Acid and lime tolerance' is vividly augmented by additional carboxyl group and they
7
8 further increase with increase in the length of spacer group between two carboxyl groups
9
10 increase. The order of acid and lime tolerance found was C₁₂Glycinate<C₁₂Aspartate<
11
12 C₁₂Glutamate. Comparison of dicarboxylamido linkage surfactants with dicarboxyl amino
13
14 linkage surfactants revealed that dicarboxyl amino linkage surfactants have wider pH range
15
16 in which surface activity increases with moderate addition of acid. Dicarboxyl N-alkyl
17
18 amino acids have a chelating effect in the presence of calcium ions and C₁₂Aspartate forms
19
20 white gel. C₁₂Glutamate shows high surface activity at high concentration of Ca⁺⁺ and has
21
22 the potential to get used in seawater desalination (Li, 2012).
23
24
25
26
27

28 **7.11. Dispersability**

29
30
31 Dispersability is the ability of surfactants to inhibit the agglomeration and settling down
32
33 of surfactants in solution. Dispersability is an important property of surfactants that make
34
35 them suitable for detergents, cosmetics and pharmaceuticals (Satyanarayana, 2012).
36
37 Dispersing agents must contain an ester, ether, amido, or amino linkage between the
38
39 hydrophobic group and the terminal hydrophilic group, as well as a straight-chain
40
41 hydrophobic group (Rosen & Kunjappu, 2012). Generally the anionic surfactants like
42
43 sulphated alkanolamide and zwitterionic surfactants such as amidosulfobetaine are found to
44
45 be very effective as lime soap dispersing agents (Linfield, 1978; Weil *et al.*, 1970; Parris *et*
46
47 *al.*, 1973; Parris *et al.*, 1976).
48
49
50
51
52

53 Various studies have been made to determine the dispersability of amino acid
54
55 surfactants, in which N-lauroyllysine was found to have poor compatibility with water and
56
57 was found difficult to make cosmetic formulations. In this series, N-acyl basic amino acid
58
59
60
61
62
63
64
65

1
2
3
4 was found to have superior dispersability and is being utilized in cosmetic industries to
5
6 improve formulations (Sagawa *et al.*, 2015).
7
8

9 **8. Toxicity**

10
11 Conventional surfactants, especially cationic surfactants are intensely toxic against
12
13 aquatic life which includes algae, fish and molluscs. Their acute toxicity is because of their
14
15 tendency to disrupt the integral membrane which is due to the adsorption-ionic interaction
16
17 phenomenon of surfactant at the cell water interface. Lowering the CMC of surfactants
18
19 typically results in greater adsorption of surfactants onto interfaces, typically raising their
20
21 acute toxicity. Increasing the length of hydrophobic chain of the surfactant molecule also
22
23 results in the increase of acute toxicity of surfactant. Low or non-toxicity of the majority of
24
25 amino acid surfactants to human and the environment, specifically to marine organisms,
26
27 make them suitable as food ingredients, medicines and cosmetics (Ito & Inoue, 1982; Berger
28
29 & Gacon, 1992; Davila *et al.*, 1997; George *et al.*, 1998; Myers, 2005; Obata *et al.*, 2008;
30
31 Sagawa *et al.*, 2015). Various researchers have verified amino acid-based surfactants as mild
32
33 and non-irritating to the skin (George *et al.*, 1998). Arginine based surfactants are known to
34
35 be less toxic than their conventional counterparts. Brito *et al.*, 2009 studied the
36
37 physicochemical and toxicological properties of amino acid-based amphiphiles and their
38
39 spontaneously formed cationic vesicles derived using tyrosine (Tyr), hydroxyproline (Hyp),
40
41 serine (Ser) and lysine (Lys and presented data for their acute toxicity to *Daphnia magna*
42
43 (IC₅₀). In this research work they synthesized cationic vesicles of
44
45 dodecyltrimethylammonium bromide (DTAB)/Lys-derivative and or Ser-/Lys-derivative
46
47 mixtures and tested their ecotoxicity and hemolytic potential and stated that all amino acid
48
49 surfactants along with their vesicle-containing mixtures showed lower ecotoxicity than the
50
51
52
53
54
55
56
57
58
59
60
61
62
63
64
65

1
2
3
4 conventionally used surfactant DTAB. Rosa *et al.*, 2007 studied the association of DNA and
5
6 stable cationic amino acid-based vesicles. As compared to conventionally used cationic
7
8 surfactants that are generally toxic, the interaction of cationic amino acid-based surfactants
9
10 appeared to be nontoxic. This cationic amino acid surfactant based on arginine, ALA, gives
11
12 spontaneously stable vesicles with some with anionic surfactants. Corrosion inhibitors based
13
14 on amino acids were also reported to be non-toxic by various researchers (Morad, 2008; de
15
16 Souza & Spinelli, 2009; Umoren *et al.*, 2009; Singh & Quraishi, 2010; Abiola & James,
17
18 2010; Barouni *et al.*, 2014). These surfactants were also found to be easy to synthesize with
19
20 high purities (up to 99%), low in cost, readily biodegradable and were completely soluble in
21
22 aqueous media. In various studies, sulfur containing amino acids based surfactants were
23
24 found to be more competent corrosion inhibitors (El-Naby, 1985; Rahim *et al.*, 1997;
25
26 Abiola, 2005; Morad, 2008; Özcan *et al.*, 2008; Chandra & Tyagi, 2013).

27
28
29
30
31
32
33 Perinelli *et al.*, 2017 in their latest investigation reported the favorable toxicological
34
35 profile of Rhamnolipids over conventional synthetic surfactants. Rhamnolipids were already
36
37 known as permeability enhancers. They have also reported the impact of Rhamnolipids on
38
39 the epithelial permeability of macromolecular drugs.
40
41

42 43 **9. Antimicrobial activity**

44
45 Antimicrobial activity of surfactants can be calculated on the basis of minimal
46
47 inhibitory concentration (MIC) (Infante *et al.*, 1984). Arginine based surfactants have been
48
49 studied in detail for their antimicrobial properties by many researchers (Franklin & Snow,
50
51 1981; Infante & Moses, 1994; Clapes *et al.*, 1999; Xia., 2001; Burczyk, 2003; Yoshimura *et*
52
53 *al.*, 2012). The gram negative bacteria were found to be more resistant to arginine based
54
55 surfactants than gram positive bacteria. Antimicrobial activity of surfactants typically
56
57
58
59
60
61
62
63
64
65

1
2
3
4 increases by the presence of hydroxyl group, cyclopropane or unsaturation within the acyl
5
6 chain. Castillo *et al.*, 2006 stated that the length of acyl chains and the positive charge that
7
8 determine the HLB of the molecule do affect their membrane disrupting property. $N\alpha$ -
9
10 acylarginine methyl ester is another important class of cationic surfactants that are known to
11
12 have broad spectrum antimicrobial activity with easy biodegradability and less or no toxicity
13
14 (Kamimura, 1973; Piera *et al.*, 1998). Studies on the interaction of $N\alpha$ -acyl arginine methyl
15
16 ester based surfactants with 1, 2-dipalmitoyl-*sn*-glycero-3-phosphocoline (DPPC) and 1, 2-
17
18 dimiristoyl-*sn*-glycero-3-phosphocoline (DMPC), model membranes, as well as with living
19
20 organisms with or without external barriers also revealed their good antimicrobial activity
21
22 (Singare & Mhatre, 2012).
23
24
25
26
27

28 **10. Biodegradability**

29
30
31 Kamimura, 1973, Shida *et al.*, 1973 and 1975, and Kubo *et al.*, 1976 extensively
32
33 studied the biodegradability of amino acid based surfactants and found that N-acylamino
34
35 acids are easily biodegrade through decomposition into amino acid and fatty acids.
36
37

38
39 Single hydrophobic chain containing surfactants are comparatively more
40
41 biodegradable than their branched counterpartssuch as Bis (Args). Typically, the more
42
43 hydrophobic the surfactant the poorer will be their biodegradability. Akinari *et al.*,
44
45 2004synthesized the amino acid surfactants based on fatty acids rich amino acid surfactants
46
47 and studied their physicochemical properties and biodegradability. Biodegradation studies
48
49 of these surfactants showed their microbial degradation between 57-73% over 14 days.
50
51 Zhang *et al.*, 2016 prepared supramolecular hydrogels mixtures of the biosurfactants based
52
53 on sodium deoxycholate (NaDC) and amino acids such as glycine (Gly), alanine (Ala),
54
55 lysine (Lys) and arginine (Arg) using different buffered solutions and claimed their unique
56
57
58
59
60
61
62
63
64
65

1
2
3
4 sensitivity towards multi-stimuli environments, their facile biodegradability and pH-
5
6 sensitiveness makes them promising and versatile vehicles for dye (or drug) delivery.
7
8

9 **11. Haemolytic activity**

10
11 Nogueira *et al.*, 2011 investigated the five anionic lysine-based amino acid
12
13 surfactants that differ on the basis of their counter ion and examined their ability to disrupt
14
15 the cell membrane under varied pH range, concentrations and incubation period. For this
16
17 purpose they used a standard hemolysis assay as a model for endosomal membranes. Results
18
19 confirmed the pH sensitive hemolytic activity and better kinetics of these surfactants at the
20
21 endosomal pH range.
22
23
24

25
26 Surfactants are known to have the capability to interact with lipid bilayer of cell
27
28 membranes. R.B.C. (red blood cell) is one of the most frequently used cellular membranes
29
30 as reference model to investigate the mechanisms of fundamental surfactant-induced
31
32 osmotic cell resistance. Pérez *et al.*, 2009 studied the mechanisms of surfactant membrane
33
34 interaction by monitoring the action of three arginine-based cationic amino acid surfactants
35
36 and five lysine-based anionic amino acid surfactants on hypotonic hemolysis. Results
37
38 revealed the dissimilar anti-haemolytic behaviours among amino acid-based surfactants,
39
40 both linked to the maximal protective concentration. Physicochemical and structural
41
42 properties of these compounds dictated the protection against hypotonic hemolysis. A good
43
44 correlation was found in between the CMC and the concentrations of cationic surfactants
45
46 that resulted in maximum protection against hypotonic hemolysis. In contrast, no correlation
47
48 was observed for the anionic surfactants. Lysine based surfactants differ only in their
49
50 counterions, this difference being responsible for their anti-hemolytic potency and the
51
52 hemolytic activities.
53
54
55
56
57
58
59
60
61
62
63
64
65

1
2
3
4 Toxicological study revealed that the capability of arginine based monomeric and
5
6 gemini surfactants to disrupt the erythrocyte membranes depends is size as well as
7
8 hydrophobicity dependent (Tavano *et al.*, 2013).
9

10
11 Pinheiro & Faustino, 2017 discussed erythrocyte interaction with N α , N ϵ -dioctyl
12
13 lysinate salts with different counterions (Li⁺, Na⁺, K⁺, Lys⁺, and Tris⁺). Surfactants
14
15 interacted with erythrocyte membranes in a biphasic way, at low concentrations through
16
17 protecting against hypotonic hemolysis and at high concentrations by inducing hemolysis.
18
19

20 21 **12. Rheological Properties** 22

23
24 Rheological properties of surfactants play a very important role to decide/predict
25
26 their applications in different industries such as food, pharmaceuticals, oil extraction and in
27
28 personal/home care products (Yang, 2002; Lin *et al.*, 2016; Kumar & Mandal, 2017). The
29
30 relation of viscoelastic characteristics and CMC of amino acid based surfactants have been
31
32 discussed by many researchers (Shrestha & Aramaki, 2009; Singh *et al.*, 2015; Saavedra *et*
33
34 *al.*, 2017).
35
36
37

38 39 **13. Industrial Applications** 40

41
42 Special structural characteristics, non-toxicity and biodegradability of AAS make
43
44 them suitable for various industrial applications.
45

46 47 **13.1. In agriculture** 48

49
50 Amino acid surfactant can be used as insecticides, herbicides and plant growth
51
52 inhibitors for agricultural means. Betaine ester surfactants are a class of cationic surfactants
53
54 that can be used as ‘temporary biocides’ and can be hydrolyzed very easily into harmless
55
56 components (Shida, *et al.*, 1973; Solans *et al.*, 1990; Tamarkin *et al.*, 2014).
57
58
59
60
61
62
63
64
65

1
2
3
4 A lawn pesticide was also reported in an US patent, that was synthesized using the
5
6 mixture of refined oils extracted from the plants of *Cupressaceae* family and an amino acid
7
8 derived surfactant solution, in which amino acid derived surfactant contributed 20 to 50%
9
10 by weight of the said solution. Herbicidal action of nonionic type amino acid-surfactant has
11
12 also been reported by various workers (Shida *et al.*, 1975).
13
14
15

16 **13.2. In laundry detergents**

17

18
19 Nowadays, the demand for amino acid based detergent formulations is increasing
20
21 globally. Amino acid surfactants are known to have better cleaning ability, foaming ability
22
23 and fabric softening properties that make them suitable to be used in house hold detergents,
24
25 shampoos, body wash etc. An amino acid surfactant derived from aspartic acid is reported as
26
27 an effective detergent with ampholytic and chelating characteristics. Less skin irritating
28
29 effects were observed by using detergent compositions made up of N-Alkyl- β -amino-
30
31 ethoxyacids (Leonard, 1976). Liquid detergent compositions made up of N-coco- β -
32
33 aminopropionate was claimed as an effective cleaning agent for grease mark on metallic
34
35 surfaces (Kennedy *et al.*, 1980; Cooper *et al.*, 1988). An aminocarboxylic surfactant,
36
37 $C_{14}CHOHCH_2NHCH_2COONa$, was also proved to have better detergency and used to clean
38
39 textiles, carpets, hair, glass etc (Miyamoto *et al.*, 1988). 2-hydroxy-3-aminopropionic acid
40
41 N,N di acetic acid derivatives were also known to incorporate stability in bleaching agents
42
43 with good complexing ability.
44
45
46
47
48
49

50
51 Detergent composition based on N-(N'-long chain acyl- β -alanyl)- β -alanine were
52
53 reported to have better ability and stability, foam breakage and good softening properties
54
55 (Miyamoto *et al.*, 1988). Keigo & Tatsuya, 1996 prepared and patented acyl amino acid
56
57 based detergent compositions. Kao formulated N-acyl-1-N-hydroxy- β -alanine based
58
59
60
61
62
63
64
65

1
2
3
4 detergent compositions and claimed their low skin irritation property, high water resistance
5
6 and high detergency (Nozaki, 1995). Ajinomoto company used low toxic and easily
7
8 degradable, L-glutamic acid, L-arginine and L-Lysine based amino acid surfactants as the
9
10 principal ingredients in shampoos, detergents and cosmetics (Fig. 9). Ability of enzymatic
11
12 additives in detergent compositions to remove protein based soilings has also been
13
14 documented in the literature (Keshwani *et al.*, 2015). Glutamic acid, alanine, methyl
15
16 glycine, serine and aspartic acid derived N-acyl amino acid surfactants were reported as
17
18 good liquid cleaning agents in aqueous solutions. These surfactants did not show any
19
20 increase in viscosity even at very low temperatures and can easily transfer from foamer
21
22 container, thus providing uniform foam (Moriyama, 1998).
23
24
25
26
27

28 **13.3. Lubricants**

30
31 Amphoteric type amino acid surfactants are generally used as lubricants. Having
32
33 excellent adhesive property for hydrophilic surfaces and low friction coefficient make them
34
35 ideally suited to be lubricants. Various researchers prepared and studied the lubricating
36
37 properties of AAS specifically glutamic acid (Jiang *et al.*, 2005; Jiang *et al.*, 2006; Xia &
38
39 Jianhua, 2007).
40
41
42

43 **13.4. In medicine**

44 **13.4.1. Drug carriers and preparation of functional liposomes**

45
46 In the recent years, various researchers have claimed the ability of synthetic acyl
47
48 amino acid/peptide as drug carrier and for preparing functional liposomes with lipopeptide
49
50 ligands. As compared to the conventional liposomes of lecithin, vesicles of long aliphatic
51
52 chain N α -acyl amino acids also showed encapsulation efficiencies for solutes (Boeckler *et*
53
54 *al.*, 1998; Yagi *et al.*, 2000).

60
61
62
63
64
65

13.4.2. Gene therapy and DNA transfection

Gene therapy is a very important technique currently used in life science to safely introduce selected gene into living cells. Gemini surfactants have been found to have potential to be used as a carrier for the transportation of bioactive molecules. Lysine and 2,4-diaminobutyric acid based polycationic gemini surfactants can be easily synthesized using standard peptide chemistry (Kirby *et al.*, 2003).

McGregor *et al.*, 2001 prepared a new class of amino acid based gemini surfactants as carrier for gene delivery into cells. Preliminary results revealed that combining these amino acid based gemini surfactants with dioleoylphosphatidylethanolamine (DOPE) allowed the synthesis of liposomes of different sizes and lipid compositions. Investigation revealed that suspensions of DOPE/surfactants mixtures in water, leads to a mixture of lipid vesicles with more complex structures corresponding to particles e500 nm in diameter. Different molar ratios of DOPE and surfactants (50/50, 60/40, and 70/30) were found to effect luciferase expression in CHO cells at comparable levels. The size of colloid and the molecular composition of the gemini surfactants matter in delivering optimum gene expression in living models.

DNA transfection efficiency of cysteine based amino acid surfactants with low molecular weight and its corresponding gemini were evaluated by Pena *et al.*, 2017. These surfactants showed no cytotoxicity and had greater efficacy than their commercially available counterparts to transfect CHO-K1 cells.

13.4.3. Antiviral agents

Lipoamino acids are attracting researchers due to their significant antiviral activity. Some acyl amino acid derivatives have also been reported to inhibit influenza

1
2
3
4 neuraminidase (Kondoh *et al.*, 2009). Several $N\alpha$ -palmitoylated amino acids/peptides when
5
6 integrated into model membranes, affected the transition temperature between the surface
7
8 tension at their critical micelle concentration (CMC).
9

10
11 Amino acid surfactants derived cationic surfactants obtained by condensation of
12
13 fatty acids such as lauric acid and esterified dibasic amino acids such as Arginine may be
14
15 exploited for the protection against the microorganism and these cationic surfactants were
16
17 also found to be effective against viral infections. Furthermore, the addition of LAE into the
18
19 cultures of Herpes virus type 1 Vaccinia virus and bovine parainfluenzae 3 virus leads to
20
21 almost complete diminution of the virus organisms in these cultures, such effects being
22
23 observed from 5 to 60 minutes (Bonvila *et al.*, 2006).
24
25
26
27

28 **13.5. In food processing industry**

29
30 Amino acid surfactants are widely used as emulsifiers in the food sectors such as in
31
32 margarine, dairy products, low-calorie spreads and dressings (Flack, 1997). In addition, new
33
34 insights into eating habits and health aspects need the changes in the food formulations time
35
36 to time in terms of calories, fat content, vitamins or minerals that lead to a constant demand
37
38 of optimizing product formulations. These surfactants also include optimal selection of raw
39
40 materials. Formerly, Industries were giving great attention to the different glycerides, most
41
42 commonly of monoglyceride derivatives but due to health consciousness, Arginine based
43
44 amino acid surfactants with antimicrobial activity and wide antibacterial spectra are
45
46 receiving great interest as a promising alternative of commercially available pure glycerides
47
48 in food formulations. These surfactants additionally show considerable antimicrobial
49
50 activity against *Escherichia coli* and *Salmonella*, which are the most common food borne
51
52 pathogens and create a serious health hazard due to increased drug resistance (Lynde, 2001).
53

61
62
63
64
65

13.6. In cosmetic industry

AAS are used in the formulation of various personal care products. Potassium N-cocoylglycinate was found to be mild to skin and applied and used in face cleansers to remove soil and make-up. N-acyl-L-glutamic acid has two carboxylic groups, which lead to better water solubility. Among these, AAS based upon C₁₂ fatty acid are extensively used in face cleansers in order to clean soil and make up. AAS with C₁₈ have found to be used as emulsifiers in skin care cosmetics. N-dodecanoylalaninate is known to have ability to create non irritating creamy foam for skin, and therefore employed to formulate baby care products. N-lauroyl based AAS is used in toothpaste shows good detergency similar to soap and strong enzyme-inhibiting efficacy (Rosen & Kunjappu, 2012).

In the past few decades, in the selection of surfactants in cosmetics, personal care products and pharmaceuticals, less toxicity, mildness, gentleness and safety are becoming the major concerns. Consumers of these products are genuinely conscious for the potential irritation, toxicity and environmental factors. Nowadays, amino acids surfactants are used to formulate many shampoos, rinses, and body soaps because of the numerous merits over their conventional counterparts for use in cosmetics and personal care products. Protein based surfactants [PBS] possess desirable properties that a personal care product must have (Linfield, 1978). Some amino acid surfactants are known to have film forming ability whereas others have good foaming ability. Amino acids are important naturally occurring moisturizing factors (NMF) present in the stratum corneum. When epidermal cells die they become a part of the stratum corneum, and the proteins present in the cells gradually degrade into amino acids. These amino acids are then transported further into the stratum corneum, absorb the fat or fatlike substances into horny layer and thus improve the elasticity

1
2
3
4 of the skin surface. About 50% of the NMF present in the skin is made up of amino acids
5
6 and pyrrolidone (Cruz & Korchin,1994). Collagen, a common cosmetic ingredient also
7
8 comprises of amino acids, which keep the skin supple. Various skin problems such as
9
10 roughness and dark colouration of the skin are largely due to the deficiency of amino acids.
11
12 A case study revealed that mixing of an amino acid with ointment give relief to skin burn
13
14 and the affected area returned to the normal state and did not turn in to a keloid (Kiran *et al.*,
15
16
17
18
19 2010).

20
21 Amino acids are also found very useful for the care of damaged cuticles. Lacklustre
22
23 and dry hair can indicate a decrease of amino acid concentration in heavily damaged
24
25 cuticles. Amino acids have the ability to penetrate through the cuticle into hair shaft and
26
27 drawing in moisture from the skin. This capability of amino acid based surfactants make
28
29 them useful in shampoos, rinses, hair softeners, hair treatment agents, and the presence of
30
31 amino acids makes hair less breakable (Franklin & Snow, 1981).
32
33
34
35

36 **13.7. In microbial enhanced oil recovery**

37
38 Amino acid surfactants are also found useful in microbial enhanced oil recovery. A
39
40 bacterium strain, *B. aureum* MSA13 synthesized an amino acid surfactant that has potential
41
42 for use in microbial oil recovery. This surfactant has octadecanoic acid as a hydrophobic
43
44 moiety and hydrophilic group comprises of a tetrapeptide, a short sequence of four amino
45
46 acids pro-leu-gly-gly. Another example involve in microbial enhanced oil recovery in
47
48 marine surroundings is an actinobacterium, MSA13 produced surfactant (Zhou *et al.*, 2011).
49
50
51

52 **13.8. In nanomaterials**

53
54 Amino-acid-based polymerizable surfactants were also found to be useful in the
55
56 synthesis of chiral nanoparticles. Preiss *et al.*, 2016 reported the synthesis of an amino-acid-
57
58
59
60
61
62
63
64
65

1
2
3
4 based chiral surfactants with polymerizable moieties which were then exploited to prepare
5
6 nanoparticles with a chiral surface functionality. They also checked their potential as
7
8 nucleating agents in the enantioselective crystallization of amino acid conglomerate systems,
9
10 taking a model system of rac-asparagine. Comparison were made in the particles synthesized
11
12 from chiral surfactants having different tail groups and results revealed that only the chiral
13
14 nanoparticles made up of polymerizable surfactant were found to have ability to act
15
16 efficiently as nucleation agent in the enantioselective crystallization.
17
18
19
20

21 **13.9. Other applications**

22
23 Amino acid surfactants are also known for use in forming PEDOT [Poly (3,4
24
25 ethylene dioxythiophene)] films (Hernandaz *et al.*, 2011; Moral-Vico *et al.*, 2013; Ahuja *et*
26
27 *al.*, 2007; Lowe , 1989; Malhotra *et al.*, 2006; Malhotra *et al.*, 2005; Andreescu & Sadik,
28
29 2004; Guimard *et al.*, 2007; Sackmann *et al.*, 1968; Sarfati *et al.*, 2000).Poly PEDOT films
30
31 through direct anodic oxidation of EDOT (3, 4-ethylenedioxythiophene) in aqueous solution
32
33 comprisingofthe sodium N-lauroylsarcosinate (SLS), an eco-friendly amino acid surfactant
34
35 were also prepared. In addition to the above mentioned applications, amino acid surfactants
36
37 are also used in the optimization of dry-cleaning process with carbon dioxide and as chiral
38
39 solvents (Sarfati *et al.*, 2001; Weiss-López *et al.*, 2001; Roosmalen *et al.*, 2004; Bordes &
40
41 Holmberg, 2015)
42
43
44
45
46
47

48 Roosmalen *et al.*, 2004 have optimized the dry-cleaning process using carbon
49
50 dioxide along with the amino acid surfactants, and studied the impact of various reaction
51
52 parameters on the cleaning. The reaction parameters studied were the cleaning time,
53
54 temperature, and power involve in mechanical action. In addition, the influence of the
55
56
57
58
59
60
61
62
63
64
65

1
2
3
4 quantity of each substance used such as CO₂, isopropyl alcohol, water and surfactant was
5
6 also investigated.
7

8
9 Self-assembly of amino acid surfactants resulted into micelles with a chiral surface.
10
11 Such a property of amino acid surfactant micelles of being supra-molecularly chiral makes
12
13 them suitable for asymmetric organic synthesis (Liu *et al.*, 2006). The chiral micelles can
14
15 also impart chirality in mesoporous materials prepared through surfactant templating route
16
17 and make their pores chiral. Dicarboxylic based amino acid surfactants can also behave like
18
19 surface-active chelating agents. It has been observed that the interaction of dicarboxylic
20
21 amino acid surfactants with divalent ion like calcium is reliant on the distance between the
22
23 two carboxyl groups. For example, N-acyl glutamate that has three –CH₂ groups between
24
25 the carboxyl groups does not form an intramolecular chelate with calcium, and is not able to
26
27 precipitate in water with high concentrations of calcium. The binding property of chelating
28
29 surfactants can also be used in mineral ore flotation. Calcium containing minerals like
30
31 calcite and apatite can be separated by means of flotation reagent with the right distance
32
33 between the carboxyl groups. N-alkyl amino acid surfactants are true amphoteric type
34
35 surfactants that can provide exceptionally low values of surface tension at the CMC, which
36
37 is due to formation of self-assemblies consisting of alternating anionic and cationic species.
38
39 This represents the micellization-driven protonation of surfactants.
40
41
42
43
44
45
46
47

48 Amino acid surfactants can also be used to design switchable surfactants. Cysteine
49
50 derivatives are the best known example of this class that can readily convert into cystine
51
52 derivatives via reversible processes. For example, long chain N-acylcystine, a gemini
53
54 surfactant, is highly surface active and can be transformed into a cysteine derivative. Dithiothreitol, a
55
56 poor surface active agent, can also revert back to the gemini surfactant via an oxidation. The
57
58
59
60
61
62
63
64
65

1
2
3
4 exchange from one state to the other can also be achieved through electrochemical means
5
6 (Fiechter, 1992).
7
8

9 **14. Current Challenges for Amino acid Surfactants**

10
11 The economic feasibility of large scale production of amino acid surfactants is a
12 major issue to be surmounted. Biotechnological processes involved in their production are
13
14 not easily cost effective especially for the processes where bulk use of surfactants is
15
16 required such as petroleum and environmental application. Purification of substances is
17
18 another problem linked with these surfactants which is a needed for pharmaceutical,
19
20 cosmetic and food applications. Along with these disadvantages, denaturation and
21
22 dissociation of amino acid surfactants into their subunits and their activity are largely
23
24 affected by salt solutions.
25
26
27
28
29

30
31 Various researchers have suggested remedies to overcome these problems. The
32
33 overall cost cutting in their production can be achieved through the utilization of waste
34
35 substrate after combating their polluting effect. Development of efficient bioprocesses and
36
37 their successful optimization is also required, which include the optimization of the culture
38
39 conditions and cost-effective recovery processes for the maximum production and recovery
40
41 (Mohamed *et al.* 2017; Wang & Dado, 2017; Vecino *et al.*, 2017).
42
43
44

45 **15. Conclusions**

46
47 Although conceptually simple the process of combining amino acids with a
48
49 hydrophobic tail can by its very nature offer a variety of synthetic routes, this in turn leading
50
51 to many potential structures. Since the first studies on the synthesis of simple amino acid
52
53 surfactants in 1909 research has extended into the production of cationic, anionic, non-ionic
54
55 and amphoteric molecules, with detailed characterisation and assessment of physiochemical
56
57
58
59
60
61
62
63
64
65

1
2
3
4 properties performed throughout. Amino acid surfactants have been shown to have wide
5
6 reaching applications over different industrial sectors, and the diversity in properties borne
7
8 out of their potential for structural variety will in the future allow for this range of
9
10 applications to grow further. Additionally, facile biodegradability and non-toxicity of amino
11
12 acid surfactants can make them superior to their conventional synthetic counterparts when
13
14 selected for the right application. Examples even exist whereby the chirality of amino acid
15
16 surfactants has been exploited in use, such as imparting chirality into the surface of micelle
17
18 template mesoporous materials. Amino acid surfactants have been reported to have a wide
19
20 range of applications in different industrial sectors. Facile biodegradability and non-toxicity
21
22 of amino acid surfactants can make them superior to their conventional synthetic
23
24 counterparts when selected for the right application. The major challenges associated with
25
26 amino acid surfactants are their high production cost and their challenging isolation to high
27
28 purity. Various researchers are working to minimize these problems through selecting
29
30 suitable renewable alternatives as substrate along with designing cost effective and scalable
31
32 procedures. Amino acids surfactants have the potential to be widely accepted commercially
33
34 in various industrial sectors in near future, especially so when the diversity of their structure
35
36 and physiochemical properties are considered.

	Reviewers' Comments	Response
1	AAS applications (regarding several technological fields) are dependent on their toxicological profile. Authors should address in a more extensive and careful way, the toxicity issue and its relationship with the physicochemical properties of AAS. Recent papers like Perinelli et al, 2016 (Eur J Pharm Biopharm) could be added to the references list.	Section 8, Toxicity has been rewritten and incorporated all the suggestions and references given by the learned reviewer.
2	The same applies to the antimicrobial activity. There is currently a very broad database on AAS biomedical applications. It is mandatory to incorporate more up-to-date information. Examples of more recent papers are Tavano et al, 2013 (Soft Matter), Pinazo et al, 2016 (ACIS), and Coronel-Léon et al, 2017 (CSBB).	Section 9, Antimicrobial activity has been rewritten and all the suggestions and references given by the learned reviewer have been incorporated.
3	Did the authors considered the inclusion of a rheological appreciation of AAS? Besides Shrestha, R. G., &Aramaki, K. (2009), recent papers dealing with this subject seem quite appealing, since thickening, viscosity consistency and foaming are technological challenges related to many AAS industrial applications.	Rheological properties of AAS have been incorporated as a separate section (Section 12).
4	In terms of application in Medicine concerning drug delivery, the authors did not address the fact that AAS can be promising novel biomaterials in nano-particulate systems. Why?	It has been included in the manuscript in Section 12.8.
5	- Page 33, 12.4.2.: DNA transfection deserves also a more full approach. Literature reports, others than Claffe et al, 2000, are available. Furthermore, gene therapy could be included in DNA transfection item. Considering DNA transfection and Gene therapy, authors should rewrite the corresponding text in a more careful way, accurately relating the scientific results (e.g. what was the main achievement, in terms of transfection efficiency, after combining the Gemini AAS with DOPE?)	Gene therapy and DNA transfection have clubbed and the section 12.4.2. is dedicated to it.

<p>size for gemini surfactants was significantly larger than their monomeric counterparts." Any citation?</p> <p>- Page 23, line -3: rephrase "In an another study (Bordes et al.,2009) investigated the solution behavior and adsorption of three dicarboxylic amino acid-based surfactants....."</p> <p>- Page 24, 7.8: More details (although briefly) and references are needed for this part.</p> <p>- Page 29, 10: Change the order to: "Kamimura, 1973, Shida et al., 1973 & 1975 and Kubo et al., 1976 extensively....."</p> <p>- Page 30, line -12.: the reference "145" is not in the same style of referencing as the others.</p> <p>- Page 30, 11: a more comprehensible explanation is needed for the interaction surfactant-erythrocyte membrane.</p> <p>- Page 33, 12.4.2.: DNA transfection deserves also a more full approach. Literature reports, others than Claffe et al, 2000, are available.</p> <p>- Figure 1: a more careful use of capital letters must be taken into account (an example is the caption of Figure 1).</p> <p>- Figure 1: the information about the meaning of this pKa is missing. pKa presented here is the value of side chain.</p> <p>- Figure 3: should be presented in a more careful manner.</p> <p>Figures 4, 5, 6 and 7: better structures representations are needed.</p> <p>- Figure 7: authors should use always the same notation throughout the text (e.g. "bolaamphiphiles" or "bola amphiphiles").</p> <p>- Figure 10 should be better presented, in order to address the corresponding caption.</p>	<p>Correction has been made</p> <p>Correction has been made</p> <p>Correction has been made</p> <p>Correction has been made</p> <p>Explanation has been added as per reviewer suggestions</p> <p>Corrections have been made accordingly</p> <p>Corrections have been made accordingly</p> <p>Figure 3 has been deleted</p> <p>Corrections have been made</p> <p>Corrections have been made</p> <p>Figure 10, which is now Figure 9 has been redrawn.</p>

Scheme 4: Synthesis of symmetric bolaamphiphiles derived from tris(hydroxymethyl)aminomethane (Tris)

	CAE	NAE	LAE	MAE
CMC (mg/L)	>1500	820±50	410±10	350±30
γ (mN/m)	27.0±0.5	26.1±0.5	25.5±0.5	24.0±0.5

Table 1: CMC and surface tension of N α -Acyl arginine surfactants

CAE= N- α -Octanoyl-L-Arginine ethyl ester, NAE= N- α -Nonanoyl-L-Arginine ethyl ester, LAE= Ethyl-N- α - lauroyl-L-arginate, MAE= N- α -Myristoyl-L-Arginine ethyl ester
