# The structure of (theta, pyramid, 1-wheel, 3-wheel)-free graphs 

Valerio Boncompagni *, Marko Radovanović ${ }^{\dagger}$ and Kristina Vušković ${ }^{\ddagger}$

August 4, 2018

#### Abstract

In this paper we study the class of graphs $\mathcal{C}$ defined by excluding the following structures as induced subgraphs: thetas, pyramids, 1 -wheels and 3 -wheels. We describe the structure of graphs in $\mathcal{C}$, and we give a polynomial-time recognition algorithm for this class. We also prove that $K_{4}$-free graphs in $\mathcal{C}$ are 4 -colorable. We remark that $\mathcal{C}$ includes the class of chordal graphs, as well as the class of line graphs of triangle-free graphs.

Key words: structure, decomposition, clique cutsets, bisimplicial cutsets, 2-amalgams, recognition algorithm, vertex coloring

AMS Classification (2010): 05C75, 05C85

## 1 Introduction

Throughout the paper all graphs are finite and simple. We say that a graph $G$ contains a graph $F$, if $F$ is isomorphic to an induced subgraph of $G$, and it is $F$-free if it does not contain $F$. For a family of graphs $\mathcal{F}$ we say that $G$ is $\mathcal{F}$-free if $G$ is $F$-free for every $F \in \mathcal{F}$. A hole in a graph is a chordless cycle of length at least 4 , and it is even or odd depending on the parity of its length.
In 1982 Truemper [18] gave a theorem that characterizes graphs whose edges can be labeled so that all chordless cycles have prescribed parities. The characterization states that this can be done for a graph $G$ if an only if it can be done for all induced subgraphs of $G$ that are of few specific types (depicted in Figure 1, note that in all figures solid lines denote an edge and a dashed line denotes a chordless path containing one or more edges), which we will call Truemper configurations, and will describe precisely later. We observe that in Figure 1 we have depicted a wheel in which the center vertex has 4 neighbors on the outer hole, but in general it can have any number of neighbors, greater than 2 , on the outer hole. Truemper was originally motivated by the problem of obtaining a co-NP characterization of bipartite

[^0]graphs that are signable to be balanced (i.e. bipartite graphs whose vertex-vertex adjacency matrices are balanceable matrices, a class of matrices that have important polyhedral properties).

Figure 1: Truemper configurations and $K_{4}$

The configurations that Truemper identified in his theorem later played an important role in understanding the structure of several seemingly diverse classes of objects, such as regular matroids, balanceable matrices, perfect graphs, odd-hole-free and even-hole-free graphs (for a survey see [19]). All these classes were studied using the decomposition method. In these decomposition theorems Truemper configurations appear both as excluded structures that are convenient to work with, and as structures around which the actual decomposition takes place.
In this paper we study the class $\mathcal{C}$ of (theta, pyramid, 1 -wheel, 3 -wheel)-free graphs, which we formally define in Section 1.2. Observe that this is a hereditary class of graphs defined by excluding only cyclic structures. This class contains all chordal graphs and all line graphs of triangle-free graphs (or equivalently, (claw, diamond)-free graphs [10]). This class was first studied in [1] where it was shown that every graph in $\mathcal{C}$ has a vertex whose neighborhood is a disjoint union of two (possibly empty) cliques, and furthermore an ordering of such vertices can be found by LexBFS. A consequence of this is a linear-time algorithm for the maximum weight clique problem on $\mathcal{C}$, as well as a linear-time coloring algorithm that colors the graph with at most $2 \omega(G)-1$ colors, where $\omega(G)$ denotes the size of the largest clique in $G$. Coloring is NP-hard on line graphs of triangle-free graphs, and in fact it is NP-hard on ( $K_{4}$, claw, diamond)-free graphs [11]. The complexity of the stable set problem on $\mathcal{C}$ is open, and in fact it is open even for the subclass of $K_{4}$-free graphs in $\mathcal{C}$. On the other hand, stable set problem is polynomial-time solvable on line graphs - one just computes the root graph using the linear algorithm from [13] and then uses Edmond's algorithm from [8] to find a maximal matching in the root graph.
In this paper we describe the structure of graphs in $\mathcal{C}$, and as a consequence we obtain a series of decomposition theorems that use cutsets that combine star cutsets and 2-joins in the simplest possible ways. These theorems present a good setting for studying various problems, and in particular the stable set problem restricted to the class $\mathcal{C}$. Two much studied hereditary graph classes are even-hole-free graphs and perfect graphs (see for example surveys [19] and [17]). The complexity of the stable set problem on even-hole-free graphs is still not known, and also it is not known how to solve the stable set problem in polynomial time for perfect graphs by a purely graph theoretic algorithm (it is known that this problem can be solved in polynomial time for perfect graphs using the ellipsoid method [9]). The known decomposition theorems for these classes use star cutsets and 2-joins, as well as different generalizations of these. It is not clear how to make use of star cutsets for the stable set problem (and
other problems), and therefore it would be of interest to understand how very structured star cutsets, such as the ones used in this paper, behave in algorithms.
The paper is organized as follows. In Sections 1.1 and 1.2 we introduce the terminology and notation that will be used throughout the paper. In Section 1.3 we give an overview of subclasses of $\mathcal{C}$ that were studied in literature. In Section 1.4 we give an overview of the complexity of recognizing different Truemper configurations, and in Section 2 we give two polynomial-time recognition algorithms for $\mathcal{C}$. In Section 1.5 we describe the structure of graphs in $\mathcal{C}$, which we prove in Sections 3 and 4 . In Section 5, using the structure theorem for $\mathcal{C}$, we prove that $K_{4}$-free graphs in $\mathcal{C}$ are 4 -colorable.

### 1.1 Terminology and notation

Let $G$ be a graph. The vertex set of $G$ is denoted by $V(G)$. Sometimes, when clear from context, for notational simplicity we will refer to $V(G)$ with just $G$. For $x \in V(G), N(x)$ is the set of all neighbors of $x$ in $G$, and $N[x]=N(x) \cup\{x\}$. For $S \subseteq V(G), G[S]$ denotes the subgraph of $G$ induced by $S$, $G \backslash S=G[V(G) \backslash S], N(S)$ denotes the set of vertices in $V(G) \backslash S$ with at least one neighbor in $S$, and $N[S]=N(S) \cup S$. Note that, if $S$ is empty, then $N(S)=N[S]=\varnothing$.
Let $A$ and $B$ be two disjoint subsets of $V(G)$. $A$ is complete to $B$ if every vertex of $A$ is adjacent to every vertex of $B$, and $A$ is anticomplete to $B$ if no vertex of $A$ is adjacent to a vertex of $B$. Given a set $A \subset V(G)$ and a vertex $u \in V(G) \backslash A$, we will also say that $u$ is complete (resp. anticomplete) to $A$ if it is adjacent (resp. non-adjacent) to every vertex of $A$.
A path $P$ is a sequence of distinct vertices $x_{1}, \ldots, x_{k}, k \geq 1$, such that $x_{i} x_{i+1}$ is an edge for all $1 \leq i<k$. These are called the edges of $P$. Vertices $x_{1}$ and $x_{k}$ are the endpoints of the path. The vertices of $P$ that are not endpoints of $P$ are called the interior vertices of $P$. Let $x_{i}$ and $x_{j}$ be two vertices of $P$ such that $1 \leq i \leq j \leq k$. The path $x_{i}, x_{i+1}, \ldots, x_{j}$ is called the $x_{i} x_{j}$-subpath of $P$, and is denoted by $P^{x_{i} x_{j}}$. For a $x_{1} x_{k}$-path $P$ and a subset $S$ of the vertex set of $P$, we say that a vertex $u \in S$ is closest to $x_{1}$ if $V\left(P^{x_{1} u}\right) \cap S=\{u\}$. A cycle $C$ is a sequence of vertices $x_{1}, \ldots, x_{k}, x_{1}, k \geq 3$, such that vertices $x_{1}, \ldots, x_{k}$ form a path and $x_{1} x_{k}$ is an edge. The edges of the path $x_{1}, \ldots, x_{k}$, together with the edge $x_{1} x_{k}$, are called the edges of $C$. Let $Q$ be a path or a cycle. The vertex set of $Q$ is denoted by $V(Q)$. The length of $Q$ is the number of edges in $Q$.
Given a path or a cycle $Q$ in a graph $G$, any edge of $G$ between vertices of $Q$ that is not an edge of $Q$ is called a chord of $Q . Q$ is chordless if no edge of $G$ is a chord of $Q$. As mentioned earlier, a hole is a chordless cycle of length at least 4. It is called a $k$-hole if it has $k$ edges. A $k$-hole is even if $k$ is even, and it is odd otherwise.
In a graph $G$, a clique is a (possibly empty) subset of $V(G)$ consisting of pairwise adjacent vertices. The size of a largest clique in $G$ is denoted by $\omega(G)$. A complete graph is a graph whose vertex set is a clique in that graph. A complete graph on $n$ vertices is denoted by $K_{n}$, and a $K_{3}$ is also referred to as a triangle.
Given a graph $G$, a subset $S$ of vertices and edges is a cutset if its removal results in a disconnected graph. A cutset $S$ is a clique cutset if $S$ is a clique. Note that a graph with no clique cutset is connected. A cutset $S$ is a star cutset if, for some vertex $x \in S, S \subseteq N[x]$.
A wheel $(H, x)$ is a graph induced by a hole $H$, called the rim, and a vertex $x$, called the center, that has at least three neighbors on $H$. A sector of a wheel is a subpath of the rim, of length at least 1 , whose endpoints are adjacent to the center, but whose interior vertices are not. A sector is said to be short if it is of length 1 , and long otherwise.

Throughout the paper, when we refer to a wheel $(H, x)$, we will use the following associated terminology and notation. Let $x_{1}, \ldots, x_{n}$ be the neighbors of $x$ on $H$, appearing in this order when traversing $H$. For every $1 \leq i \leq n$, the sector of $(H, x)$ with endpoints $x_{i}$ and $x_{i+1}$ (we assume that $x_{n+1}=x_{1}$ ) will be denoted by $S_{i}$ (and throughout we will also assume that $S_{n+1}=S_{1}$ ). If $S_{i}$ is a long sector, then we denote by $x_{i}^{\prime}\left(\right.$ resp. $\left.x_{i+1}^{\prime}\right)$ the neighbor of $x_{i}$ (resp. $x_{i+1}$ ) in $S_{i}$. (We observe that the wheels in the class we will work with in this paper do not have consecutive long sectors, and hence $x_{i}^{\prime}$ and $x_{i+1}^{\prime}$ are well defined). Also, for a long sector $S_{i}$, the hole induced by $V\left(S_{i}\right) \cup\{x\}$ will be denoted by $H_{i}$.
A $k$-coloring of a graph $G$ is a function $c: V(G) \rightarrow\{1, \ldots, k\}$ such that $c(u) \neq c(v)$ whenever $u v \in E(G)$. A graph $G$ is $k$-colorable if there exists a $k$-coloring of $G$. The chromatic number of $G$, denoted by $\chi(G)$, is the least $k$ for which there exists a $k$-coloring of $G$.

### 1.2 Truemper configurations

The first three configurations in Figure 1 are referred to as 3-path-configurations ( $3 P C$ 's). They are structures induced by three paths $P_{1}, P_{2}$ and $P_{3}$, in such a way that, for every $i \neq j$, the vertices of $P_{i}$ and $P_{j}$ induce a hole. More specifically, a $3 P C(x, y)$ is a structure induced by three paths that connect two non-adjacent vertices $x$ and $y$; a $3 P C\left(x_{1} x_{2} x_{3}, y\right)$, where $x_{1} x_{2} x_{3}$ is a triangle, is a structure induced by three paths having endpoints $x_{1}, x_{2}$ and $x_{3}$ respectively and a common endpoint $y$; a $3 P C\left(x_{1} x_{2} x_{3}, y_{1} y_{2} y_{3}\right)$, where $x_{1} x_{2} x_{3}$ and $y_{1} y_{2} y_{3}$ are two vertex-disjoint triangles, is a structure induced by three paths $P_{1}, P_{2}$ and $P_{3}$ such that, for every $1 \leq i \leq 3$, path $P_{i}$ has endpoints $x_{i}$ and $y_{i}$. We say that a graph $G$ contains a $3 P C(\cdot, \cdot)$ if it contains a $3 P C(x, y)$ for some $x, y \in V(G)$, a $3 P C(\triangle, \cdot)$ if it contains a $3 P C\left(x_{1} x_{2} x_{3}, y\right)$ for some $x_{1}, x_{2}, x_{3}, y \in V(G)$, and a $3 P C(\triangle, \triangle)$ if it contains a $3 P C\left(x_{1} x_{2} x_{3}, y_{1} y_{2} y_{3}\right)$ for some $x_{1}, x_{2}, x_{3}, y_{1}, y_{2}, y_{3} \in V(G)$. Note that the condition that the vertices of $P_{i}$ and $P_{j}$, for $i \neq j$, must induce a hole, implies that all paths of a $3 P C(\cdot, \cdot)$ have length greater than one, and at most one path of a $3 P C(\triangle, \cdot)$ has length one. In literature a $3 P C(\cdot, \cdot)$ is also referred to as a theta, a $3 P C(\triangle, \cdot)$ as a pyramid, and a $3 P C(\triangle, \triangle)$ as a prism.
We refer to 3-path-configurations and wheels as Truemper configurations.
A wheel is a 1 -wheel if for some consecutive vertices $x, y, z$ of the rim, the center is adjacent to $y$, but not to $x$ and $z$. A wheel is a 2 -wheel if for some consecutive vertices $x, y, z$ of the rim, the center is adjacent to $x$ and $y$, but not to $z$. A wheel is a 3 -wheel if for some consecutive vertices $x, y, z$ of the rim, the center is adjacent to $x, y$ and $z$. Observe that a wheel can simultaneously be a 1 -wheel, a 2 -wheel and a 3 -wheel, and that every wheel is a 1 -wheel, a 2 -wheel or a 3 -wheel.
An alternating wheel is a wheel whose sectors alternate between short and long sectors. A line wheel is an alternating wheel with exactly two long sectors and two short sectors. A long alternating wheel is an alternating wheel that is not a line wheel.
From now on we will denote by $\mathcal{C}$ the class of (theta, pyramid, 1 -wheel, 3 -wheel)-free graphs. Note that the only Truemper configurations that these graphs may contain are prisms and alternating wheels.

### 1.3 Some subclasses of $\mathcal{C}$

The class $\mathcal{C}$ clearly contains all chordal graphs (i.e. hole-free graphs). We now describe some other subclasses of $\mathcal{C}$ that were studied in literature.
Let $G$ be a graph and $x$ and $y$ two non-adjacent vertices of $G$. The separability of $x$ and $y$, is the minimum cardinality of a set $S \subseteq V(G)$ such that $x$ and $y$ are in different components of $G \backslash S$. The separability
of $G$ is the maximum over all separabilities of pairs of non-adjacent vertices of $G$ (unless $G$ is complete, in which case it has separability 0 ). So the graphs of separability at most $k$ are precisely the graphs in which every two non-adjacent vertices can be separated by removing a set of at most $k$ other vertices. By Menger's Theorem, the separability of $G$ is equal to the maximum number of internally vertex-disjoint paths connecting two non-adjacent vertices. Graphs of separability at most 2 were studied in [4] where the following characterization is obtained, and a number of other properties of this class. $K_{5}^{-}$is the graph obtained from a $K_{5}$ by removing a single edge.

Theorem 1.1 (Cicalese and Milanič [4]) A graph $G$ is of separability at most 2 if and only if it is ( $K_{5}^{-}$, theta, pyramid, prism, wheel)-free.

Let $\gamma$ be a $\{0,1\}$-vector whose entries are in one-to-one correspondence with the holes of a graph $G$. A graph $G$ is universally signable if for all choices of vector $\gamma$, there exists a subset $F$ of the edge set of $G$ such that $|F \cap H| \equiv \gamma_{H}(\bmod 2)$, for all holes $H$ of $G$. By the above mentioned theorem of Truemper [18], it is easy to obtain the following characterization of universally signable graphs in terms of forbidden induced subgraphs.

Theorem 1.2 (Conforti, Cornuéjols, Kapoor and Vušković [5]) A graph is universally signable if and only if it is (theta, pyramid, prism, wheel)-free.

This characterization of universally signable graphs is then used to obtain the following decomposition theorem, which generalises the classical decomposition of chordal graphs with clique cutsets.

Theorem 1.3 (Conforti, Cornuéjols, Kapoor and Vušković [5]) A connected universally signable graph is either a complete graph or a hole, or it admits a clique cutset.

Clique cutsets have been studied extensively in literature and it is well understood how to use them in algorithms. So, in particular, Theorem 1.3 implies efficient algorithms for recognition of universally signable graphs, and for coloring, maximum clique and maximum stable set problems on this class.
As already observed, the only Truemper configurations that graphs in $\mathcal{C}$ may contain are prisms and alternating wheels. Graphs that may contain only prisms (and no other Truemper configuration) are studied in [6] where the following decomposition theorem is obtained. Given a graph $G$, its line graph $L(G)$ is a graph such that each vertex of $L(G)$ represents an edge in $G$ and two vertices of $L(G)$ are adjacent if and only if their corresponding edges share a common endpoint in $G$. A graph is chordless if all of its cycles are chordless.

Theorem 1.4 (Diot, Radovanović, Trotignon and Vušković [6]) If $G$ is (theta, pyramid, wheel)free, then $G$ is the line graph of a triangle-free chordless graph or it admits a clique cutset.

A claw is the complete bipartite graph with three vertices on one side of the bipartition and one vertex on the other. A diamond is the graph on four vertices that has exactly one pair of non-adjacent vertices. Note that the class of (claw, diamond)-free graphs is a subclass of $\mathcal{C}$.

Theorem 1.5 (Harary and Holzmann [10], see also Lemma 3.19 in [16]) A graph is the line graph of a triangle-free graph if and only if it is (claw, diamond)-free.

By Theorem 1.5, the class of line graphs of triangle-free graphs is a subclass of $\mathcal{C}$. The main result in this paper is to show that graphs in $\mathcal{C}$ that are not line graphs of triangle-free graphs have a particular structure.

### 1.4 Recognizing Truemper configurations

A natural question to ask is whether Truemper configurations can be recognized in polynomial time. These questions in fact arose when studying how to recognize even-hole-free graphs and perfect graphs in polynomial time. Observe that if a graph contains a prism or a theta, then it must contain an even hole, and if it contains a pyramid, then it must contain an odd hole. In fact, the class of even-hole-free graphs is included in the class of (theta, prism, even wheel)-free graphs (where an even wheel is a wheel with an even number of sectors), and the class of odd-hole-free graphs, and hence perfect graphs, is included in the class of (pyramid, odd wheel)-free graphs (where an odd wheel is a wheel with an odd number of short sectors). We now briefly describe different general techniques that were developed when trying to recognize whether a graph contains a particular Truemper configuration.
In [2] it is shown that detecting whether a graph contains a pyramid can be done in $\mathcal{O}\left(n^{9}\right)$ time. This algorithm is based on the shortest-paths detector technique developed by Chudnovsky and Seymour. The idea of their algorithm is as follows. If $G$ has a pyramid, then it has a pyramid $\Sigma$ with fewest number of vertices. The algorithm "guesses" some vertices of $\Sigma$, and then finds shortest paths in $G$ between the guessed vertices that are joined by a path in $\Sigma$. If the graph induced by the union of these paths is a pyramid, then clearly $G$ contains a pyramid. If it is not, then it turns out that $G$ is pyramid-free.
Chudnovsky and Seymour [3] show that detecting whether a graph contains a theta can be done in $\mathcal{O}\left(n^{11}\right)$ time. For this detection problem, the shortest-paths detector technique does not work. The detection of thetas relies on being able to solve a more general problem called the three-in-a-tree problem defined as follows: given a graph $G$ and three specified vertices $a, b$ and $c$, the question is whether $G$ contains a tree that passes through $a, b$ and $c$. It is shown in [3] that this problem can be solved in $\mathcal{O}\left(n^{4}\right)$ time. What is interesting is that the algorithm for the three-in-a-tree problem is based on an explicit construction of the cases when the desired tree does not exist, and that this construction can be directly converted into an algorithm. The three-in-a-tree algorithm is quite general, and can be used to solve different detection problems, including the detection of a theta, and of a pyramid (the latter in $\mathcal{O}\left(n^{10}\right)$ time).
Maffray and Trotignon show that detecting whether a graph contains a prism is NP-complete [14]. Also, detecting whether a graph contains a wheel is NP-complete, as shown by Diot, Tavenas and Trotignon [7]. In fact they prove that the problem remains NP-complete even when restricted to bipartite graphs. Since all wheels in bipartite graphs are 1-wheels, it follows that recognizing whether a graph is 1-wheel-free is NP-complete. A number of other detection problems related to graph classes defined by excluding some combination of Truemper configurations have been studied in literature. In Section 2 we will give two polynomial-time recognition algorithms for $\mathcal{C}$.

### 1.5 The structure of graphs in $\mathcal{C}$

We say that a connected graph $G$ is structured if there exists a partition

$$
\mathcal{S}=\left(\{x\}, X_{1}, X_{2}, X_{3}, Y_{1}, Y_{2}, Y_{3}, C_{1}, C_{2}, C_{3}, C_{X}, C_{Y}\right)
$$

of $V(G)$ that satisfies the following:
(i) For $1 \leq i \leq 2, X_{i}, Y_{i}$ and $C_{i}$ are all non-empty. There exist $x_{1} \in X_{1}, x_{2} \in X_{2}$ such that $x_{1}$ is complete to $X_{2} \cup X_{3}$ and $x_{2}$ is complete to $X_{1} \cup X_{3}$, and $y_{1} \in Y_{1}, y_{2} \in Y_{2}$ such that $y_{1}$ is complete to $Y_{2} \cup Y_{3}$ and $y_{2}$ is complete to $Y_{1} \cup Y_{3}$.
(ii) Let $X=X_{1} \cup X_{2} \cup X_{3}$ and $Y=Y_{1} \cup Y_{2} \cup Y_{3}$. Then $x$ is complete to $X \cup Y$ and $X$ is anticomplete to $Y$. Also, for every $1 \leq i, j \leq 3, i \neq j, X_{i} \cup Y_{i}$ is anticomplete to $C_{j}$, and for $1 \leq i \leq 3$ every vertex of $X_{i} \cup Y_{i}$ has a neighbor in $C_{i}$.
(iii) For every $1 \leq i \leq 3, X_{i}$ and $Y_{i}$ are both cliques, and $X_{3}$ (resp. $Y_{3}$ ) is complete to $X_{1} \cup X_{2}$ (resp. $\left.Y_{1} \cup Y_{2}\right)$.
(iv) $C_{1}, C_{2}, C_{3}, C_{X}$ and $C_{Y}$ are pairwise anticomplete to each other.
(v) $N\left(C_{X}\right) \subseteq X \cup\{x\}$ and $N\left(C_{Y}\right) \subseteq Y \cup\{x\}$.

If $G$ is structured, we also say that $\mathcal{S}$ is a structured partition of $G$. We prove the following theorem.
Theorem 1.6 If $G \in \mathcal{C}$ is not a line graph of a triangle-free graph and does not admit a clique cutset, then it is structured.

The following decomposition theorems are immediate corollaries of Theorem 1.6.
A cutset $S$ is a bisimplicial cutset if, for some vertex $x \in S, S \subseteq N(x) \cup\{x\}$ and $S \backslash\{x\}$ is the disjoint union of two cliques of size at least 2 that are anticomplete to each other.
A 2-amalgam $\left(K, V_{1}, V_{2}\right)$ of a connected graph $G$ is a partition of $V(G)$ into subsets $V_{1}, V_{2}$ and $K$ such that, for every $1 \leq i \leq 2, W_{i}$ and $Z_{i}$ are disjoint non-empty subsets of $V_{i}$ and the following hold:

- $V_{i} \backslash\left(W_{i} \cup Z_{i}\right) \neq \varnothing$ for every $1 \leq i \leq 2$.
- $W_{1}\left(\right.$ resp. $\left.Z_{1}\right)$ is complete to $W_{2}$ (resp. $Z_{2}$ ) and these are the only edges between $V_{1}$ and $V_{2}$.
- $K$ is a clique that is complete to $W_{1} \cup W_{2} \cup Z_{1} \cup Z_{2}$.

Note that the removal of $K$, together with the edges with one end in $V_{1}$ and one in $V_{2}$, disconnects $G$. A 2-amalgam is called special if $K$ consists of a single vertex, $W_{i}$ and $Z_{i}$ are cliques for every $1 \leq i \leq 2$ and $W_{1}\left(\right.$ resp. $\left.W_{2}\right)$ is anticomplete to $Z_{1}\left(\right.$ resp. $\left.Z_{2}\right)$. A 2-amalgam is small if it is special and $\left|W_{i}\right|=\left|Z_{i}\right|=1$ for every $1 \leq i \leq 2$. Note that if $G$ admits a special 2 -amalgam, then it has a bisimplicial cutset, that satisfies additional properties.

Theorem 1.7 If $G \in \mathcal{C}$, then $G$ is the line graph of a triangle-free graph or it admits a clique cutset or a bisimplicial cutset.

Proof. If $G$ is not the line graph of a triangle-free graph and does not admit a clique cutset then, by Theorem 1.6, it is structured. First observe that, for $1 \leq i \leq 2,\{x\} \cup X_{i} \cup Y_{i}$ is a cutset of $G$ separating $C_{i}$ from the rest of the graph. Now suppose that $\{x\} \cup X_{1} \cup Y_{1}$ is not a bisimplicial cutset. Then w.l.o.g. $\left|X_{1}\right|=1$. If $\left|Y_{1}\right|=1$ or $\left|Y_{2}\right|=1$ then $\{x\} \cup X_{1} \cup X_{2} \cup Y_{1} \cup Y_{2}$ is a bisimplicial cutset. So we may assume that $\left|Y_{1}\right| \geq 2$ and $\left|Y_{2}\right| \geq 2$. But then $\{x\} \cup X_{1} \cup X_{2} \cup Y_{1}$ is a bisimplicial cutset.

Theorem 1.8 If $G \in \mathcal{C}$ is a $K_{4}$-free graph, then $G$ is the line graph of a triangle-free graph or it admits a clique cutset or a small 2-amalgam.

Proof. Assume otherwise. By Theorem 1.6 we may assume that $G$ is structured. If $G$ is $K_{4}$-free, then $\left|X_{1}\right|=\left|X_{2}\right|=\left|Y_{1}\right|=\left|Y_{2}\right|=1$ and $X_{3} \cup Y_{3} \cup C_{3}=\varnothing$. Also, since $X$ and $Y$ are both cliques and $G$ does not admit a clique cutset, $C_{X}=C_{Y}=\varnothing$. Therefore, if we define $K=\{x\}, W_{1}=\left\{x_{1}\right\}, Z_{1}=\left\{y_{1}\right\}$, $W_{2}=\left\{x_{2}\right\}, Z_{2}=\left\{y_{2}\right\}, V_{1}=W_{1} \cup Z_{1} \cup C_{1}$ and $V_{2}=W_{2} \cup Z_{2} \cup C_{2}$, then $\left(K, V_{1}, V_{2}\right)$ is a small 2-amalgam of $G$, a contradiction.

Theorem 1.9 If $G \in \mathcal{C}$ is a $K_{5}^{-}$-free graph, then $G$ is the line graph of a triangle-free graph or it admits a clique cutset or a special 2-amalgam.

Proof. Assume not. By Theorem $1.6 G$ is structured. When $G$ is $K_{5}^{-}$-free, $X$ and $Y$ must both be cliques and therefore $C_{X}=C_{Y}=\varnothing$. So, if $K=\{x\}, W_{1}=X_{1}, Z_{1}=Y_{1}, W_{2}=X_{2} \cup X_{3}, Z_{2}=Y_{2} \cup Y_{3}$, $V_{1}=W_{1} \cup Z_{1} \cup C_{1}$ and $V_{2}=W_{2} \cup Z_{2} \cup C_{2} \cup C_{3}$, then $\left(K, V_{1}, V_{2}\right)$ is a special 2-amalgam of $G$, a contradiction.

As intermediate results, we also prove the following three theorems. Let $(H, x)$ be a wheel of a graph $G \in \mathcal{C}$. Then we say that a chordless path $P=p_{1}, \ldots, p_{k}, k>2$, in $G \backslash(V(H) \cup\{x\})$ is an appendix of $(H, x)$ that attaches to $S_{i}$ if, for some long sector $S_{i}$ of $(H, x), N\left(p_{1}\right) \cap(V(H) \cup\{x\})=\left\{x, x_{i}\right\}$, $N\left(p_{k}\right) \cap(V(H) \cup\{x\})=\left\{x_{i}, x_{i}^{\prime}\right\}$ and $N\left(p_{j}\right) \cap(V(H) \cup\{x\}) \subseteq\left\{x_{i}\right\}$ for every $1<j<k$.

Theorem 1.10 If $G \in \mathcal{C}$ does not contain a wheel with an appendix nor a long alternating wheel, then $G$ is the line graph of a triangle-free graph or it admits a clique cutset.

Theorem 1.11 If $G \in \mathcal{C}$ does not contain a wheel with an appendix, then $G$ is the line graph of a triangle-free graph, or it admits a clique cutset or a special 2-amalgam.

Theorem 1.12 If $G \in \mathcal{C}$ contains a wheel with an appendix or a long alternating wheel, then $G$ admits a clique cutset or $G$ is structured.

Theorem 1.6 follows directly from Theorem 1.10 and Theorem 1.12. Theorem 1.10 is proved in Section 3 , and Theorems 1.11 and 1.12 are proved in Section 4.
The following result is proved in Section 5.
Theorem 1.13 If $G \in \mathcal{C}$ is a $K_{4}$-free graph, then $G$ is 4 -colorable.

## 2 Recognizing graphs in $\mathcal{C}$

In this section we give two polynomial-time algorithms that decide whether an input graph $G$ belongs to $\mathcal{C}$. The first algorithm is obtained by a direct search for certain Truemper configurations, so, although it is slower than the second one, we believe that its intermediate steps are of independent interest. The second algorithm has running time $\mathcal{O}\left(n^{5}\right)$ and is based on the description of the local structure of graphs in $\mathcal{C}$ that is obtained in [1]. (Throughout the section, for a graph $G$ we let $n=|V(G)|$ and $m=|E(G)|)$. Both of these algorithms do not use our main decomposition theorem for $\mathcal{C}$ (Theorem 1.7).
In [15], Maffray, Trotignon and Vušković give an $\mathcal{O}\left(n^{7}\right)$-time algorithm that decides whether a graph contains a theta or a pyramid. Recall that deciding whether a graph contains a 1 -wheel is NP-complete [7]. In Lemma 2.1 we give an $\mathcal{O}\left(n^{6}\right)$-time algorithm that decides whether a graph contains a theta, a
pyramid or a 1 -wheel. In Lemma 2.2 we give an $\mathcal{O}\left(n^{6}\right)$-time algorithm that decides whether a graph contains a 3 -wheel. Together these two algorithms give our first recognition algorithm for $\mathcal{C}$.

Lemma 2.1 There is an algorithm with the following specifications:
Input: $A$ graph $G$.
Output: YES if $G$ contains a theta, a pyramid or a 1-wheel, and NO otherwise.
Running time: $\mathcal{O}\left(n^{4} m+n^{5}\right)$.

Proof. Consider the following algorithm.
Step 1: Let $\mathcal{L}$ be the set of all 4-element subsets of $V(G)$.
Step 2: If $\mathcal{L}=\varnothing$, then return NO. Otherwise, take $S \in \mathcal{L}$ and remove $S$ from $\mathcal{L}$.
Step 3: If $S$ does not induce a claw, go to Step 2. Otherwise, let $S=\{u, a, b, c\}$ be such that $u$ is complete to $\{a, b, c\}$.

Step 4: If there exists a connected component $C$ of $G \backslash N[u]$ such that $a, b$ and $c$ all have a neighbor in $C$, then return YES. Otherwise, go to Step 2.

Since $\mathcal{L}$ has $\mathcal{O}\left(n^{4}\right)$ elements, and Step 4 takes $\mathcal{O}(n+m)$ time, the running time of this algorithm is $\mathcal{O}\left(n^{4} m+n^{5}\right)$.
Let us now prove its correctness. First suppose that, for some connected component $C$ of $G \backslash N[u]$ (in Step 4), all $a, b$ and $c$ have a neighbor in $C$, and let $C^{\prime}$ be a minimal connected subgraph of $C$ such that all $a, b$ and $c$ have a neighbor in $C^{\prime}$. Let $P$ be a chordless $a c$-path in the graph induced by $V\left(C^{\prime}\right) \cup\{a, c\}$. If $b$ has a neighbor in $P$, then $V(P) \cup\{u, b\}$ induces a theta or a 1-wheel. Otherwise, let $Q$ be a chordless $b v$-path of $G\left[V\left(C^{\prime}\right) \cup\{b\}\right]$ such that $v$ has a neighbor in $P \backslash\{a, c\}$ and no vertex of $Q \backslash\{v\}$ has a neighbor in $P \backslash\{a, c\}$. By minimality of $C^{\prime}$, not both $a$ and $c$ can have a neighbor in $Q$, and $v$ has one or two adjacent neighbors in $P$. So w.l.o.g. $N(c) \cap V(Q)=\varnothing$. Let $H$ be the hole contained in $G[(V(P) \backslash\{a\}) \cup V(Q) \cup\{u\}]$ that contains $Q, u$ and $c$. If $a$ has at least three neighbors in $H$, then $(H, a)$ is a 1-wheel. If $a$ has exactly two neighbors in $H$, then $V(H) \cup\{a\}$ induces a theta. So we may assume that $a$ has no neighbors in $H \backslash\{u\}$. But then the graph induced by $V(P) \cup V(Q) \cup\{u\}$ is a theta or a pyramid. It follows that the algorithm correctly returns YES in Step 4.
So, let us assume that the output is NO, but that $G$ contains a theta, pyramid or a 1 -wheel $D$. Let $\{u, a, b, c\}$ induce a claw contained in $D$ and let $u$ be complete to $\{a, b, c\}$. Additionally, in case $D$ is a 1 -wheel, then w.l.o.g. we assume that $b$ is its center. So, clearly a connected component of $G \backslash N[u]$ has neighbors from all of $a, b$ and $c$, and hence the algorithm returns YES in Step 4, a contradiction.

Lemma 2.2 There is an algorithm with the following specifications:
Input: $A$ graph $G$.
Output: YES if $G$ contains a 3-wheel, and NO otherwise.
Running time: $\mathcal{O}\left(n^{4} m+n^{5}\right)$.

Proof. Consider the following algorithm.
Step 1: Let $\mathcal{L}$ be the set of all 4-element subsets of $V(G)$.
Step 2: If $\mathcal{L}=\varnothing$, then return NO. Otherwise, take $S \in \mathcal{L}$ and remove $S$ from $\mathcal{L}$.
Step 3: If $S$ does not induce a diamond, go to Step 2. Otherwise, let $S=\{a, b, x, y\}$ be such that $a b$ is not an edge.

Step 4: Let $N_{x}=N[x] \backslash\{a, b\}$ and $N_{y}=N[y] \backslash\{a, b\}$. If $a$ and $b$ are in the same connected component of $G \backslash N_{x}$ or in the same component of $G \backslash N_{y}$, then return YES. Otherwise, go to Step 2.

Since $\mathcal{L}$ has $\mathcal{O}\left(n^{4}\right)$ elements, and Step 4 takes $\mathcal{O}(n+m)$ time, the running time of this algorithm is $\mathcal{O}\left(n^{4} m+n^{5}\right)$.
Let us now prove that the algorithm is correct. First, if the output is YES, then $G$ contains a 3 -wheel with center $x$ or $y$. Indeed, if $a$ and $b$ are in the same connected component $C$ of $G \backslash N_{z}$, for some $z \in\{x, y\}$, then a shortest path from $a$ to $b$ in $C$, together with $\{x, y\}$, induces a 3 -wheel with center $t$, where $t \in\{x, y\} \backslash\{z\}$.

So, let us assume that the output is NO, but that $G$ contains a 3 -wheel. Let $(H, x)$ be this 3 -wheel, and let $a, b, y \in V(H) \cap N(x)$ be such that $a$ and $b$ are distinct neighbors of $y$. The vertex set $\{a, b, x, y\}$ induces a diamond and $a$ and $b$ are in the same connected component of $G \backslash N_{y}$. Therefore, the algorithm returns YES in Step 4, a contradiction.

To describe our second algorithm, we first recall some definitions from [1]. Let $\mathcal{F}$ be a set of graphs. A graph $G$ is locally $\mathcal{F}$-decomposable if for every vertex $v$ of $G$, every $F \in \mathcal{F}$ contained in $N(v)$ and every connected component $C$ of $G \backslash N[v]$, there exists $y \in F$ such that $y$ has a non-neighbor in $F$ and no neighbors in $C$. A class of graphs $\mathcal{G}$ is locally $\mathcal{F}$-decomposable if every graph $G \in \mathcal{G}$ is locally $\mathcal{F}$-decomposable.

Let $S_{3}$ denote the stable graph on three vertices and $P_{3}$ the path on three vertices. The following theorem is the key for our second algorithm (we note that the class $\mathcal{C}$ is denoted by $\mathcal{C}_{4}$ in [1] - see also Table 1 from the same paper).

Theorem 2.3 ([1]) The class $\mathcal{C}$ is exactly the class of locally $\left\{S_{3}, P_{3}\right\}$-decomposable graphs.
Theorem 2.4 There is an algorithm with the following specifications:
Input: $A$ graph $G$.
Output: YES if $G$ is in $\mathcal{C}$, and $N O$ otherwise.
Running time: $\mathcal{O}\left(n^{5}\right)$.
Proof. Consider the following algorithm.
Step 1: Let $\mathcal{L}=V(G)$.
Step 2: If $\mathcal{L}=\varnothing$, then return YES. Otherwise, take $v \in \mathcal{L}$ and remove $v$ from $\mathcal{L}$. Let $\mathcal{L}_{v}$ be the set of all 3-element subsets of $N(v)$ and $\mathcal{C}_{v}$ the set of all connected components of $G \backslash N[v]$.

Step 3: If $\mathcal{L}_{v}=\varnothing$, go to Step 2. Otherwise, take $S \in \mathcal{L}_{v}$ and remove $S$ from $\mathcal{L}_{v}$.
Step 4: If $S$ does not induce $S_{3}$ nor $P_{3}$, go to Step 3. Otherwise, for every $y \in S$ and every $C \in \mathcal{C}_{v}$ find $N(y) \cap C$ and $N(y) \cap S$. If the first set is empty and the second is not equal to $S \backslash\{y\}$ for some $y \in S$ and $C \in \mathcal{C}_{v}$, go to Step 3. Otherwise, return NO.

Let $v \in \mathcal{L}$. The set $\mathcal{L}_{v}$ has $\mathcal{O}\left(n^{3}\right)$ elements and $\mathcal{C}_{v}$ can be found in time $\mathcal{O}(n+m)$, so Step 2 takes $\mathcal{O}\left(n^{3}\right)$ time (for every $v \in \mathcal{L}$ ). Step 4 takes $\mathcal{O}(n)$ time (since $\left|\bigcup_{C \in \mathcal{C}_{v}} C\right|<n$ and $|S|=3$ ), so the running time of the algorithm is $\mathcal{O}\left(n \cdot n^{3} \cdot n\right)=\mathcal{O}\left(n^{5}\right)$.

The correctness of the algorithm follows directly from Theorem 2.3.

## 3 Proof of Theorem 1.10

The following easy observation will be used throughout the paper.
Lemma 3.1 Let $G \in \mathcal{C}$ and let $H$ be a hole contained in $G$. If $x \in V(G) \backslash V(H)$ has at least two non-adjacent neighbors in $H$, then $(H, x)$ is an alternating wheel.

Proof. If $x$ has exactly two neighbors in $H$, and they are not adjacent, then $G[V(H) \cup\{x\}]$ is a theta. So assume $x$ has at least three neighbors in $H$. Then $(H, x)$ is a wheel, and hence an alternating wheel.

Theorem 1.10 immediately follows from Theorem 1.5 and from the two results below, whose proof is postponed to Section 3.1 and Section 3.2, respectively.

Theorem 3.2 Assume that $G \in \mathcal{C}$ does not contain a wheel with an appendix. If $G$ contains a diamond, then it admits a clique cutset.

Theorem 3.3 Assume that $G \in \mathcal{C}$ is a diamond-free graph that does not contain a long alternating wheel. If $G$ contains a claw, then it admits a clique cutset.

### 3.1 Proof of Theorem 3.2

In order to prove Theorem 3.2, it is convenient to work with extended diamonds. Given a graph $G$, let $K=\left\{v_{1}, \ldots, v_{\ell}\right\}, \ell \geq 2$, be a clique of $G$ of size $\ell$. An extended diamond $D=(K, x, y)$ of $G$ is an induced subgraph of $G$ with vertex set $V(D)$ given by the disjoint union of $K$ and $\{x, y\}$, and such that $x$ and $y$ are distinct, non-adjacent and both complete to $K$. We say that an extended diamond $D$ of $G$ is maximum if $G$ does not contain an extended diamond with more vertices. The above terminology and notation will be used throughout. Note that $D$ is a diamond when $\ell=2$.

Lemma 3.4 Let $D=(K, x, y)$ be a maximum extended diamond of a graph $G \in \mathcal{C}$. Then for every vertex $u \in V(G) \backslash V(D), N(u) \cap V(D)$ is a clique of size at most $\ell+1$.

Proof. Assume not. Then $x, y \in N(u) \cap V(D)$. Since, for every $1 \leq i, j \leq \ell, i \neq j,\left\{x, y, v_{i}, v_{j}, u\right\}$ cannot induce a 3-wheel, $u$ is complete to $V(D)$. Let $K^{\prime}=K \cup\{u\}$. Then the extended diamond induced by $K^{\prime} \cup\{x, y\}$ contradicts the maximality of $D$.

Proof of Theorem 3.2. Let $D=(K, x, y)$ be a maximum extended diamond of $G$. We prove that $K$ is a clique cutset of $G$ separating $x$ from $y$. Assume not and let $Q=q_{1}, \ldots, q_{r}$ be a shortest path in $G \backslash V(D)$ such that $q_{1}$ (resp. $q_{r}$ ) is adjacent to $x$ (resp. $y$ ). By Lemma 3.4, $r \geq 2$. By minimality of $Q$, $Q$ is chordless, no vertex of $Q \backslash\left\{q_{1}\right\}$ is adjacent to $x$ and no vertex of $Q \backslash\left\{q_{r}\right\}$ is adjacent to $y$, so that $N\left(q_{i}\right) \cap V(D) \subseteq K$ for every $1<i<r$.
Since the graph induced by $V(Q) \cup V(D)$ cannot contain a 3 -wheel, $v_{i}$ has a neighbor in $Q$ for every $1 \leq i \leq \ell$. Let $q_{j}$ be the vertex of $Q$ with lowest index that has a neighbor in $K$. W.l.o.g. $v_{1} q_{j} \in E(G)$.
(1) $q_{j}$ is not complete to $K$.

Proof of (1). Suppose it is. If $j>1$, then $V\left(Q^{q_{1} q_{j}}\right) \cup\left\{x, v_{2}\right\}$ induces a hole $H$ and $\left(H, v_{1}\right)$ is a 3 -wheel, a contradiction. So, $j=1$.
We now prove that $q_{2}$ is complete to $K$. Assume otherwise and w.l.o.g. suppose that $v_{2} q_{2}$ is not an edge. Since $V(Q) \cup\left\{v_{1}, v_{2}, y\right\}$ cannot induce a 3 -wheel, $v_{1}$ and $v_{2}$ both have a neighbor in $Q^{q_{2} q_{r}}$. Let $q_{k}$ (resp. $q_{h}$ ) be the vertex of $Q^{q_{2} q_{r}}$ with lowest index that is adjacent to $v_{1}$ (resp. $v_{2}$ ). If $k=h$ then $k>2$, and hence $V\left(Q^{q_{1} q_{k}}\right) \cup\left\{v_{1}, v_{2}\right\}$ induces a 3 -wheel, a contradiction. So w.l.o.g. $k<h$. Let $H$ be the hole induced by $V\left(Q^{q_{1} q_{h}}\right) \cup\left\{v_{2}\right\}$. Then, by Lemma 3.1, $\left(H, v_{1}\right)$ is an alternating wheel and hence $v_{1}$ is not adjacent to $q_{h}$. Let $q_{m}$ be the neighbor of $v_{1}$ in $Q^{q_{1} q_{h}}$ with highest index. Note that $k<m<h$. Suppose that $N\left(v_{1}\right) \cap V\left(Q^{q_{h+1} q_{r}}\right)=\varnothing$. Since, by Lemma 3.1, $V\left(Q^{q_{m} q_{r}}\right) \cup\left\{y, v_{1}, v_{2}\right\}$ must induce an alternating wheel with center $v_{2}$, then $h<r-1$ and $v_{2}$ is adjacent to $q_{h+1}$. It follows that the chordless path induced by $V\left(Q^{q_{h+1} q_{r}}\right) \cup\{y\}$ is an appendix of $\left(H, v_{1}\right)$, a contradiction. So, let $q_{s}$ be the neighbor of $v_{1}$ in $Q^{q_{h+1} q_{r}}$ with lowest index and let $H^{\prime}$ be the hole induced by $V\left(Q^{q_{m} q_{s}}\right) \cup\left\{v_{1}\right\}$. By Lemma 3.1, $\left(H^{\prime}, v_{2}\right)$ is an alternating wheel. Also, $s>h+2$ and $q_{h+1}$ and $q_{s}$ are both adjacent to $v_{2}$. But then $Q^{q_{h+1} q_{s}}$ is an appendix of $\left(H, v_{1}\right)$, a contradiction. So, $q_{2}$ is complete to $K$.
Now let $K^{\prime}=K \cup\left\{q_{1}\right\}$. Since $q_{1}$ is complete to $K, K^{\prime}$ is a clique. Also, $q_{2}$ is complete to $K^{\prime}$ and hence the extended diamond induced by $K^{\prime} \cup\left\{x, q_{2}\right\}$ contradicts the maximality of $D$.
By (1), w.l.o.g. $v_{2} q_{j} \notin E(G)$. Let $q_{k}$ be the neighbor of $v_{2}$ in $Q^{q_{j+1} q_{r}}$ with lowest index. Then $V\left(Q^{q_{1} q_{k}}\right) \cup$ $\left\{x, v_{2}\right\}$ induces a hole $H^{\prime}$ and, by Lemma 3.1, $\left(H^{\prime}, v_{1}\right)$ is an alternating wheel. So, $j>1, k>j+1$ and $v_{1}$ is adjacent to $q_{j+1}$ and not adjacent to $q_{k}$. For some $j+1 \leq h<k$, let $q_{h}$ be the neighbor of $v_{1}$ in $Q$ with highest index.
First suppose that $v_{1}$ has no neighbors in $Q^{q_{k+1} q_{r}}$. By Lemma 3.1, $V\left(Q^{q_{h} q_{r}}\right) \cup\left\{y, v_{1}, v_{2}\right\}$ must induce an alternating wheel with center $v_{2}$, and hence $k<r-1$ and $v_{2}$ is adjacent to $q_{k+1}$. But then the chordless path induced by $V\left(Q^{q_{k+1} q_{r}}\right) \cup\{y\}$ is an appendix of $\left(H^{\prime}, v_{1}\right)$, a contradiction.
Therefore, let $q_{m}$ be the neighbor of $v_{1}$ in $Q^{q_{k+1} q_{r}}$ with lowest index and let $H^{\prime \prime}$ be the hole induced by $V\left(Q^{q_{h} q_{m}}\right) \cup\left\{v_{1}\right\}$. By Lemma 3.1, $\left(H^{\prime \prime}, v_{2}\right)$ is an alternating wheel. So, $m>k+2$ and $q_{k+1}$ and $q_{m}$ are both adjacent to $v_{2}$. But then $Q^{q_{k+1} q_{m}}$ is an appendix of ( $H^{\prime}, v_{1}$ ), a contradiction. This concludes the proof of Theorem 3.2.

### 3.2 Proof of Theorem 3.3

In order to prove Theorem 3.3, we first need some preliminary results. Throughout this subsection we assume that $G$ is a diamond-free graph that belongs to $\mathcal{C}$ and does not contain a long alternating wheel.

## Extended triangles.

An extended triangle $E=\left(K, S_{1}, S_{2}\right)$ of $G$ is an induced subgraph of $G$ defined as follows: $K=\left\{u, v_{1}, v_{2}\right\}$ is a clique of $G$ of size 3 , and $S_{1}=x_{1}, \ldots, x_{n}$ and $S_{2}=y_{1}, \ldots, y_{m}$ are vertex-disjoint chordless paths in $G \backslash K$ such that

- $N\left(x_{1}\right) \cap\left(V\left(S_{2}\right) \cup K\right)=\{u\}, N\left(x_{n}\right) \cap\left(V\left(S_{2}\right) \cup K\right)=\left\{v_{1}\right\}$ and $N\left(x_{i}\right) \cap\left(V\left(S_{2}\right) \cup K\right)=\varnothing$ for every $1<i<n$.
- $N\left(y_{1}\right) \cap\left(V\left(S_{1}\right) \cup K\right)=\{u\}, N\left(y_{m}\right) \cap\left(V\left(S_{1}\right) \cup K\right)=\left\{v_{2}\right\}$ and $N\left(y_{i}\right) \cap\left(V\left(S_{1}\right) \cup K\right)=\varnothing$ for every $1<i<m$.

Note that it follows that $m, n \geq 2$. For $1 \leq i \leq 2$, let $H_{i}$ be the hole induced by $V\left(S_{i}\right) \cup\left\{u, v_{i}\right\}$. We say that an extended triangle $E$ of $G$ is minimum if $G$ does not contain an extended triangle with a smaller number of vertices. This terminology and notation will be used in Lemma 3.5 and Lemma 3.6.

Lemma 3.5 Let $E=\left(K, S_{1}, S_{2}\right)$ be a minimum extended triangle of $G$. For every vertex $z \in V(G) \backslash V(E)$, either $z$ has at most one neighbor in $K$ or $z$ is complete to $K$. Also, one of the following holds:
(i) $N(z) \cap V(E)$ is a clique of size at most 3 .
(ii) $N(z) \cap V(E)=\left\{v_{i}, w_{1}, w_{2}\right\}$, where $1 \leq i \leq 2$ and $w_{1}, w_{2}$ are adjacent vertices of $S_{3-i}$.

Proof. Assume otherwise. Since $G$ is diamond-free, either $z$ has at most a single neighbor in $K$ or $z$ is complete to $K$. W.l.o.g. we may assume that $z$ has a neighbor in $S_{1}$. Suppose that $N(z) \cap V(E) \subseteq V\left(H_{1}\right)$. Since (i) does not hold, by Lemma 3.1, $\left(H_{1}, z\right)$ is an alternating wheel. But then $G[V(E) \cup\{z\}]$ contains an extended triangle with fewer vertices than $E$, a contradiction. It follows that $z$ has a neighbor in $H_{2} \backslash\{u\}$.
Suppose that $v_{2} \in N(z) \cap V(E) \subseteq V\left(S_{1}\right) \cup K$. If $z$ has a single neighbor in $H_{1}$, then such a neighbor belongs to $S_{1}$ and $V\left(H_{1}\right) \cup\left\{z, v_{2}\right\}$ induces a pyramid. So, since (ii) does not hold, by Lemma 3.1, $\left(H_{1}, z\right)$ is an alternating wheel. Then $z$ is complete to $K$, since otherwise the graph induced by $V\left(H_{1}\right) \cup\left\{z, v_{2}\right\}$ contains a $3 P C\left(u v_{1} v_{2}, z\right)$. Let $x_{i}$ be the neighbor of $z$ in $S_{1}$ with lowest index. Then $\left(K \backslash\left\{v_{1}\right\}\right) \cup$ $V\left(S_{1}^{x_{1} x_{i}}\right) \cup V\left(S_{2}\right) \cup\{z\}$ induces an extended triangle that contradicts our choice of $E$.
Therefore $z$ has a neighbor in both $S_{1}$ and $S_{2}$. Let $x_{i}$ (resp. $y_{j}$ ) be the neighbor of $z$ in $S_{1}$ (resp. $S_{2}$ ) with highest index. Assume that $z u$ is an edge but $z$ is not complete to $K$. Then $v_{1}, v_{2} \notin N(z)$, and hence (by Lemma 3.1) $x_{1}, y_{1} \in N(z)$, and so $\left\{u, z, x_{1}, y_{1}\right\}$ induces a diamond. If $z$ is complete to $K$, then by Lemma 3.1, $\left(H_{1}, z\right)$ and $\left(H_{2}, z\right)$ are both alternating wheels and $(K \backslash\{u\}) \cup V\left(S_{1}^{x_{i} x_{n}}\right) \cup V\left(S_{2}^{y_{j} y_{m}}\right) \cup\{z\}$ induces an extended triangle with a smaller number of vertices. It follows that $z$ is not adjacent to $u$. Let $x_{l}$ (resp. $y_{k}$ ) be the neighbor of $z$ in $S_{1}$ (resp. $S_{2}$ ) with lowest index and let $H=V\left(H_{1}\right) \cup V\left(S_{2}^{y_{1} y_{k}}\right) \cup\{z\}$. If $V\left(H_{1}\right) \cup\{z\}$ induces an alternating wheel, then $G[H]$ contains a $3 P C(u, z)$. If $z$ has two neighbors in $H_{1}$ and they are adjacent, then $H$ induces a pyramid. So, by symmetry, $x_{l}$ and $y_{k}$ are the only neighbors of $z$ in $E$. If $x_{l} \neq x_{1}$, then $H$ induces a $3 P C\left(u, x_{l}\right)$. If $x_{l}=x_{1}$, then $V\left(H_{1}\right) \cup V\left(S_{2}^{y_{k} y_{m}}\right) \cup\left\{z, v_{2}\right\}$ induces a 1-wheel with center $u$, a contradiction.

Lemma 3.6 If $G$ contains an extended triangle, then it admits a clique cutset.

Proof. Let $E=\left(K, S_{1}, S_{2}\right)$ be a minimum extended triangle of $G$, and let $W$ be the set of vertices of $G \backslash V(E)$ that are complete to $K$. We prove that $K \cup W$ is a clique cutset of $G$ separating $S_{1}$ from $S_{2}$. First consider the following claim.
(1) $K \cup W$ is a clique of $G$.

Proof of (1). Assume not. Then there exist two vertices $w_{1}, w_{2} \in W, w_{1} \neq w_{2}$, such that $w_{1} w_{2}$ is not an edge. It follows that $\left\{v_{1}, v_{2}, w_{1}, w_{2}\right\}$ induces a diamond, a contradiction.

By (1), we only need to show that $K \cup W$ is a cutset of $G$ separating $S_{1}$ from $S_{2}$. Assume otherwise and let $Q=q_{1}, \ldots, q_{r}$ be a shortest path in $G \backslash(K \cup W)$ such that $q_{1}$ (resp. $q_{r}$ ) has a neighbor in $S_{1}$ (resp. $S_{2}$ ). By Lemma 3.5, $r \geq 2$. By minimality of $Q, Q$ is chordless and no vertex of $Q \backslash\left\{q_{1}\right\}$ (resp. $Q \backslash\left\{q_{r}\right\}$ ) has a neighbor in $S_{1}$ (resp. $S_{2}$ ), and so $N\left(q_{i}\right) \cap V(E) \subset K$ for every $1<i<r$. By Lemma 3.5, every vertex of $Q$ has at most one neighbor in $K$.
(2) $q_{1}\left(\right.$ resp. $\left.q_{r}\right)$ has a single neighbor in $S_{1}\left(\right.$ resp. $\left.S_{2}\right)$.

Proof of (2). Suppose that $q_{1}$ has two adjacent neighbors in $S_{1}$ and no other neighbors in $H_{1}$. Let $y_{i}$ be the neighbor of $q_{r}$ in $S_{2}$ with lowest index. If $u$ and $v_{1}$ do not have a neighbor in $Q \backslash\left\{q_{1}\right\}$, then $V\left(H_{1}\right) \cup V\left(S_{2}^{y 1 y_{i}}\right) \cup V(Q)$ induces a pyramid. So, for some $1<j \leq r$, let $q_{j}$ be the vertex of $Q$ with lowest index that is adjacent to a vertex of $\left\{u, v_{1}\right\}$. But then $V\left(H_{1}\right) \cup V\left(Q^{q_{1} q_{j}}\right)$ induces a pyramid, a contradiction. By Lemma 3.5, it follows that $q_{1}$ has a single neighbor in $S_{1}$ and, by symmetry, $q_{r}$ has a single neighbor in $S_{2}$.

By Lemma 3.5 and $(2), N\left(q_{1}\right) \cap V(E) \subset V\left(H_{1}\right)$ and $N\left(q_{r}\right) \cap V(E) \subset V\left(H_{2}\right)$ are both cliques of size at most 2. Assume that $K$ is not anticomplete to $V(Q)$ and let $q_{i}$ (resp. $q_{j}$ ) be the vertex of $Q$ with lowest (resp. highest) index that has a neighbor in $K$.
(3) $q_{i}$ and $q_{j}$ are adjacent to $u$.

Proof of (3). Suppose that $q_{i}$ is not adjacent to $u$. If $q_{i}$ is adjacent to $v_{2}$, then $i>1$, and by (2), $V\left(H_{1}\right) \cup V\left(Q^{q_{1} q_{i}}\right) \cup\left\{v_{2}\right\}$ induces a pyramid, a contradiction. So, $q_{i}$ is adjacent to $v_{1}$. If $x_{n} q_{1}$ is not an edge then, by (2), $V\left(H_{1}\right) \cup V\left(Q^{q_{1} q_{i}}\right)$ induces a theta. So, $q_{1}$ is adjacent to $x_{n}$ and has no other neighbors in $S_{1}$. Let $R$ be the chordless $u q_{i}$-path contained in the graph induced by $V\left(S_{2}\right) \cup V\left(Q^{q_{i} q_{r}}\right) \cup\{u\}$. Then $V\left(H_{1}\right) \cup V\left(Q^{q_{1} q_{i}}\right) \cup V(R)$ induces a 1-wheel with center $v_{1}$, a contradiction. It follows that $q_{i}$ is adjacent to $u$ and, by symmetry, so is $q_{j}$.
Note that $N\left(q_{1}\right) \cap V\left(S_{1}\right)=\left\{x_{1}\right\}$, since otherwise, by (2) and (3), $V\left(H_{1}\right) \cup V\left(Q^{q_{1} q_{i}}\right)$ induces a theta. By symmetry, $N\left(q_{r}\right) \cap V\left(S_{2}\right)=\left\{y_{1}\right\}$. Also, $i \neq j$, since otherwise the vertex set $V(E) \cup V(Q)$ induces a 1-wheel with center $u$.
(4) $\left\{v_{1}, v_{2}\right\}$ is anticomplete to $V(Q)$.

Proof of (4). Assume not, w.l.o.g. suppose that $v_{1}$ has a neighbor in the interior of $Q^{q_{i} q_{j}}$ and, for some $i<k<j$, let $q_{k}$ be the vertex of $Q$ with lowest index that is adjacent to $v_{1}$. Then $V\left(H_{1}\right) \cup V\left(Q^{q_{1} q_{k}}\right)$ induces a 1 -wheel with center $u$, a contradiction.
By (4), $V(E) \cup V(Q)$ induces a 1 -wheel, a 3 -wheel or a long alternating wheel with center $u$. It follows that $K$ is anticomplete to $V(Q)$. By $(2), q_{1}$ (resp. $q_{r}$ ) has a single neighbor in $E$ which belongs to $S_{1}$ (resp. $S_{2}$ ). If $N\left(q_{1}\right) \cap V\left(S_{1}\right)=\left\{x_{1}\right\}$ and $N\left(q_{r}\right) \cap V\left(S_{2}\right)=\left\{y_{1}\right\}$, then $V\left(S_{1}\right) \cup V\left(S_{2}\right) \cup V(Q) \cup\left\{v_{1}, v_{2}\right\}$
induces a hole $H$ and $(H, u)$ is a 1 -wheel. So w.l.o.g. $x_{1}$ is not the neighbor of $q_{1}$ in $S_{1}$. But then the graph induced by $\left(V(E) \backslash\left\{v_{2}\right\}\right) \cup V(Q)$ contains a theta, a contradiction.

## Unichord cycles.

A unichord cycle $U=\left(u, v, S_{1}, S_{2}\right)$ of $G$ is an induced subgraph of $G$ defined as follows: $u$ and $v$ are adjacent vertices of $G$ and, for some $m, n \geq 2, S_{1}=x_{1}, \ldots, x_{n}$ and $S_{2}=y_{1}, \ldots, y_{m}$ are vertex-disjoint chordless paths in $G \backslash\{u, v\}$ such that

- $N\left(x_{1}\right) \cap\left(V\left(S_{2}\right) \cup\{u, v\}\right)=\{u\}, N\left(x_{n}\right) \cap\left(V\left(S_{2}\right) \cup\{u, v\}\right)=\{v\}$ and $N\left(x_{i}\right) \cap\left(V\left(S_{2}\right) \cup\{u, v\}\right)=\varnothing$ for every $1<i<n$.
- $N\left(y_{1}\right) \cap\left(V\left(S_{1}\right) \cup\{u, v\}\right)=\{u\}, N\left(y_{m}\right) \cap\left(V\left(S_{1}\right) \cup\{u, v\}\right)=\{v\}$ and $N\left(y_{i}\right) \cap\left(V\left(S_{1}\right) \cup\{u, v\}\right)=\varnothing$ for every $1<i<m$.

For $1 \leq i \leq 2$, let $H_{i}$ be the hole induced by $V\left(S_{i}\right) \cup\{u, v\}$. We say that a unichord cycle $U$ of $G$ is minimum if $G$ does not contain a unichord cycle with a smaller number of vertices. This terminology and notation will be used in Lemma 3.7 and Lemma 3.8.

Lemma 3.7 Let $U=\left(u, v, S_{1}, S_{2}\right)$ be a minimum unichord cycle of $G$. For every vertex $z \in V(G) \backslash V(U)$, one of the following holds:
(i) $N(z) \cap V(U)$ is a clique of size at most 2 .
(ii) $|N(z) \cap V(U)|=4,\{u, v\} \subset N(z)$ and $\left(H_{i}, z\right)$ is a line wheel for some $1 \leq i \leq 2$.

Proof. Assume otherwise. W.l.o.g. we may assume that $z$ has a neighbor in $S_{1}$. If $z$ has non-adjacent neighbors in $H_{1}$ then, by Lemma 3.1, $\left(H_{1}, z\right)$ is a line wheel. Suppose that $N(z) \cap V(U) \subseteq V\left(H_{1}\right)$. Since (i) and (ii) do not hold, $V\left(H_{1}\right) \cup\{z\}$ induces a line wheel and $z$ is not complete to $\{u, v\}$. But then $G[V(U) \cup\{z\}]$ contains a unichord cycle that contradicts our choice of $U$.
It follows that $z$ has a neighbor in both $S_{1}$ and $S_{2}$. Let $x_{i}$ (resp. $y_{j}$ ) be the neighbor of $z$ in $S_{1}$ (resp. $\left.S_{2}\right)$ with highest index. If $z$ is complete to $\{u, v\}$, then $\left(H_{1}, z\right)$ and $\left(H_{2}, z\right)$ are both line wheels and $V\left(S_{1}^{x_{i} x_{n}}\right) \cup V\left(S_{2}^{y_{j} y_{m}}\right) \cup\{v, z\}$ induces a unichord cycle with a smaller number of vertices. Therefore, w.l.o.g. $z$ is not adjacent to $v$. Let $H=V\left(H_{1}\right) \cup V\left(S_{2}^{y_{j} y_{m}}\right) \cup\{z\}$. Suppose that $\left(H_{1}, z\right)$ is a line wheel. If $j>1$ then $G[H]$ contains a $3 P C(v, z)$. So $j=1$, and hence either $G[H]$ contains a $3 P C\left(u z y_{1}, v\right)$ (if $z u$ is an edge) or $G\left[V\left(H_{1}\right) \cup\left\{y_{1}, z\right\}\right]$ contains a $3 P C(u, z)$ (otherwise). Therefore, $\left(H_{1}, z\right)$ is not a line wheel. If $z$ has two neighbors in $H_{1}$, then by Lemma 3.1 they are adjacent, and hence $G[H]$ is a pyramid (if $j>1$ ) or $G\left[V\left(H_{1}\right) \cup\left\{y_{1}, z\right\}\right]$ is a pyramid (if $j=1$ and $z$ is not adjacent to $u$ ), or $G[V(U) \cup\{z\}]$ is a 3 -wheel with center $u$ (otherwise). So by symmetry we may assume that $N(z) \cap V(U)=\left\{x_{i}, y_{j}\right\}$. If $i=j=1$ (resp. $i=n$ and $j=m$ ) then $V(U) \cup\{z\}$ induces a 1 -wheel with center $u$ (resp. $v$ ). If $i<n$ then either $G[H]$ is a $3 P C\left(v, x_{i}\right)$ (if $j>1$ ) or $G\left[V\left(H_{1}\right) \cup\left\{y_{1}, z\right\}\right]$ is a $3 P C\left(u, x_{i}\right)$ (otherwise). So $i=n$. But then $V\left(H_{1}\right) \cup V\left(S_{2}^{y_{1} y_{j}}\right) \cup\{z\}$ induces a $3 P C\left(u, x_{n}\right)$, a contradiction.

Lemma 3.8 If $G$ contains a unichord cycle, then it admits a clique cutset.

Proof. Assume not and let $U=\left(u, v, S_{1}, S_{2}\right)$ be a minimum unichord cycle of $G$. By Lemma 3.6, $G$ does not contain an extended triangle. Since $\{u, v\}$ is not a clique cutset of $G$ separating $S_{1}$ from $S_{2}$, let $Q=q_{1}, \ldots, q_{r}$ be a shortest path in $G \backslash\{u, v\}$ such that $q_{1}$ (resp. $q_{r}$ ) has a neighbor in $S_{1}$ (resp. $S_{2}$ ). By Lemma 3.7, $r \geq 2$. By minimality of $Q, Q$ is chordless and no vertex of $Q \backslash\left\{q_{1}\right\}$ (resp. $Q \backslash\left\{q_{r}\right\}$ ) has a neighbor in $S_{1}\left(\right.$ resp. $\left.S_{2}\right)$, so that $N\left(q_{i}\right) \cap V(U) \subseteq\{u, v\}$ for every $1<i<r$.
(1) No vertex of $Q$ is complete to $\{u, v\}$.

Proof of (1). Assume not and let $q_{i}$ be such a vertex with lowest index. Suppose that a vertex of $Q^{q_{1} q_{i-1}}$ has a neighbor in $\{u, v\}$, and let $q_{j}$ be such a vertex with highest index. Then $V\left(H_{2}\right) \cup V\left(Q^{q_{j} q_{i}}\right)$ induces an extended triangle, a contradiction. So, $V\left(Q^{q_{1} q_{i-1}}\right)$ is anticomplete to $\{u, v\}$. If $i=1$ then by Lemma 3.7, $G\left[V(U) \cup\left\{q_{1}\right\}\right]$ contains an extended triangle. So $i>1$, and by symmetry $i<r$. Let $x_{l}$ be the neighbor of $q_{1}$ in $S_{1}$ with lowest index. If $l=n$ then $V\left(H_{1}\right) \cup V\left(Q^{q_{1} q_{i}}\right)$ induces a pyramid. So $l<n$, and hence, by Lemma 3.7, $V\left(H_{2}\right) \cup V\left(S_{1}^{x_{1} x_{l}}\right) \cup V\left(Q^{q_{1} q_{i}}\right)$ induces an extended triangle, a contradiction.
(2) $\{u, v\}$ is anticomplete to $V(Q)$.

Proof of (2). Assume not and let $q_{i}$ be the vertex of $Q$ with lowest index that has a neighbor in $\{u, v\}$. W.l.o.g. suppose that $q_{i}$ is adjacent to $u$. By (1), vqi is not an edge. If $N\left(q_{1}\right) \cap V\left(S_{1}\right) \neq\left\{x_{1}\right\}$ then, by Lemma 3.7, $V\left(H_{1}\right) \cup V\left(Q^{q_{1} q_{i}}\right)$ either induces a theta or a pyramid. So, $q_{1}$ is adjacent to $x_{1}$ and has no other neighbors in $S_{1}$. Let $R$ be the chordless $v q_{i}$-path contained in the graph induced by $V\left(S_{2}\right) \cup V\left(Q^{q_{i} q_{r}}\right) \cup\{v\}$. Then by (1), $V\left(H_{1}\right) \cup V\left(Q^{q_{1} q_{i}}\right) \cup V(R)$ induces a 1-wheel with center $u$, a contradiction.
(3) $q_{1}\left(\right.$ resp. $\left.q_{r}\right)$ has a single neighbor in $S_{1}\left(\right.$ resp. $\left.S_{2}\right)$.

Proof of (3). Suppose that $q_{1}$ has at least two neighbors in $S_{1}$. Then, by Lemma 3.7 and (1), $q_{1}$ has two adjacent neighbors in $S_{1}$ and no other neighbors in $U$. Let $y_{i}$ be the neighbor of $q_{r}$ in $S_{2}$ with lowest index. By (2), $u$ and $v$ do not have a neighbor in $Q$. W.l.o.g. we may assume that $i<m$. But then $V\left(H_{1}\right) \cup V\left(S_{2}^{y_{1} y_{i}}\right) \cup V(Q)$ induces a pyramid, a contradiction. So by symmetry, (3) holds.

By (2) and (3), N( $\left.q_{1}\right) \cap V(U)=\left\{x_{i}\right\}$ for some $1 \leq i \leq n, N\left(q_{r}\right) \cap V(U)=\left\{y_{j}\right\}$ for some $1 \leq j \leq m$ and no interior vertex of $Q$ has a neighbor in $U$. If either $i=j=1$ or $i=n$ and $j=m$, then the vertex set $V(U) \cup V(Q)$ induces a 1-wheel with center $u$ or $v$. So w.l.o.g. $1<i \leq n$ and $1 \leq j<m$. But then $V\left(H_{1}\right) \cup V\left(S_{2}^{y_{1} y_{j}}\right) \cup V(Q)$ induces a $3 P C\left(u, x_{i}\right)$, a contradiction.

## Putting things together.

We are now ready to prove Theorem 3.3.
Proof of Theorem 3.3. Let $C$ be a claw contained in $G$, with vertex set $V(C)=\left\{u, v_{1}, v_{2}, v_{3}\right\}$ and edge set $E(C)=\left\{u v_{1}, u v_{2}, u v_{3}\right\}$, and assume that $G$ does not admit a clique cutset. Since $u$ is not a cut vertex of $G$, there exists a path $Q=q_{1}, \ldots, q_{r}$ in $G \backslash\left\{u, v_{1}, v_{2}, v_{3}\right\}$ such that $q_{1}$ is adjacent to $v_{i}$ for some $1 \leq i \leq 3$ and $q_{r}$ has a neighbor in $\left\{v_{1}, v_{2}, v_{3}\right\} \backslash\left\{v_{i}\right\}$. Assume that the claw and the path are chosen so that $Q$ is of shortest length, and w.l.o.g. suppose that $q_{1}$ is adjacent to $v_{1}$ and $q_{r}$ is adjacent to $v_{2}$. It follows that $Q$ is chordless, no vertex of $Q \backslash\left\{q_{1}\right\}$ is adjacent to $v_{1}$, no vertex of $Q \backslash\left\{q_{r}\right\}$ is adjacent to $v_{2}$, and $v_{3}$ is anticomplete to $V(Q) \backslash\left\{q_{1}, q_{r}\right\}$. Also, $G$ is diamond-free, so, by minimality of $Q$, $u$ has no neighbors in $Q$, and hence $V(Q) \cup\left\{u, v_{1}, v_{2}\right\}$ induces a hole $H$. If $v_{3}$ is adjacent to $q_{1}$ or $q_{r}$, then $V(H) \cup\left\{v_{3}\right\}$ either induces a theta or a 1 -wheel with center $v_{3}$. So, $v_{3}$ has no neighbors in $Q$.

Since $\{u\}$ is not a clique cutset of $G$, there exists a path $T=t_{1}, \ldots, t_{\ell}$ in $G \backslash\left(V(H) \cup\left\{v_{3}\right\}\right)$ such that $t_{1}$ is adjacent to $v_{3}$ and $t_{\ell}$ has a neighbor in $V(H) \backslash\{u\}$. In particular, let $T$ be such a path of shortest length. Then $T$ is chordless, no vertex of $T \backslash\left\{t_{1}\right\}$ is adjacent to $v_{3}$ and no vertex of $T \backslash\left\{t_{\ell}\right\}$ has a neighbor in $V(H) \backslash\{u\}$. If $t_{\ell}$ has non-adjacent neighbors in $H$ then, by Lemma 3.1, $\left(H, t_{\ell}\right)$ is a line wheel.
First assume that $t_{\ell}$ is not adjacent to $u$ and let $T^{\prime}$ be the chordless $u t_{\ell}$-path contained in the graph induced by $V(T) \cup\left\{u, v_{3}\right\}$. Then $t_{\ell}$ must have a single neighbor in $H$, and this vertex must belong to $\left\{v_{1}, v_{2}\right\}$, since otherwise the graph induced by $V(H) \cup V\left(T^{\prime}\right)$ contains a theta or a pyramid. But then $V(H) \cup V\left(T^{\prime}\right)$ induces a unichord cycle, contradicting Lemma 3.8.
Therefore $u t_{\ell}$ is an edge. Then $N\left(t_{\ell}\right) \cap\left\{v_{1}, v_{2}\right\} \neq \varnothing$, since otherwise $V(H) \cup\left\{t_{\ell}\right\}$ either induces a theta or a 1 -wheel with center $t_{\ell}$. W.l.o.g. let $t_{\ell}$ be adjacent to $v_{1}$. Since $G$ is diamond-free, it follows that $v_{2} t_{\ell}$ and $v_{3} t_{\ell}$ are not edges and hence $\ell \geq 2$. If ( $H, t_{\ell}$ ) is a line wheel, then the claw induced by $\left\{u, t_{\ell}, v_{2}, v_{3}\right\}$ and a proper subpath of $Q$ contradict our choice of $C$ and $Q$. So, $N\left(t_{\ell}\right) \cap V(H)=\left\{u, v_{1}\right\}$. Since $G$ is diamond-free, $u$ is not adjacent to $t_{\ell-1}$ and hence the graph induced by $V(H) \cup V(T)$ contains an extended triangle, contradicting Lemma 3.6. This concludes the proof of Theorem 3.3.

## 4 Proof of Theorem 1.12

Throughout this section we assume that $G \in \mathcal{C}$ contains a wheel with an appendix or a long alternating wheel, but does not admit a clique cutset. We want to show that $G$ is structured. By our assumptions, w.l.o.g. $G$ satisfies exactly one of the properties below, and we define a graph $H^{\star}$ depending on which property is satisfied.

Property 1: $G$ contains a wheel with an appendix. Let $(H, x)$ be a wheel with an appendix of $G$ with shortest $\operatorname{rim}$ and let $P=p_{1}, \ldots, p_{k}$ be its appendix with shortest length. Assume that ( $H, x$ ) has short odd sectors and $P$ is attached to $S_{2}$, and let $H^{\star}=G[V(H) \cup V(P) \cup\{x\}]$.
Property 2: $G$ does not contain an alternating wheel with an appendix, but contains a long alternating wheel. Let $(H, x)$ be a long alternating wheel of $G$ with shortest rim, assume that $(H, x)$ has short odd sectors and let $H^{\star}=G[V(H) \cup\{x\}]$.
Suppose that Property 1 holds and let $W$ be the hole induced by the vertex set $\left(V\left(S_{2}\right) \backslash\left\{x_{2}\right\}\right) \cup V(P) \cup\{x\}$. Then we say that $y \in V(G) \backslash(V(H) \cup V(P) \cup\{x\})$ is a special vertex of $G$ if it is complete to $\left\{x, x_{1}, x_{2}\right\}$, $N(y) \cap\left(V(H) \backslash\left\{x_{1}, x_{2}\right\}\right)=\varnothing$ and $\left\{p_{1}\right\} \subset N(y) \cap V(P)$ in such a way that $V(W) \cup\{y\}$ induces an alternating wheel.
We prove Theorem 1.12 by the following sequence of lemmas.
Lemma 4.1 For every vertex $y \in V(G) \backslash V\left(H^{\star}\right)$, either $N(y) \cap V\left(H^{\star}\right)$ is a clique of size at most 3, or $G$ satisfies Property 1 and $y$ is special.

We postpone the proof of Lemma 4.1 to Section 4.2.
Now let $M=V(H) \backslash\left(V\left(S_{2}\right) \cup\left\{x_{1}, x_{4}\right\}\right)$ and

$$
N= \begin{cases}\left(V\left(S_{2}\right) \backslash\left\{x_{2}, x_{3}\right\}\right) \cup V(P) & \text { if Property } 1 \text { holds }, \\ V\left(S_{2}\right) \backslash\left\{x_{2}, x_{3}\right\} & \text { if Property } 2 \text { holds } .\end{cases}
$$

Also, we denote by $A$ (resp. $B$ ) the set of vertices in $V(G) \backslash V\left(H^{\star}\right)$ that are complete to $\left\{x, x_{1}, x_{2}\right\}$ (resp. $\left.\left\{x, x_{3}, x_{4}\right\}\right)$. Note that, by Lemma $4.1, A \cap B=\varnothing$. In particular, if $u \in A$, either $u$ is a special vertex of $G$ (when Property 1 holds) or $N(u) \cap V\left(H^{\star}\right)=\left\{x, x_{1}, x_{2}\right\}$. If $u \in B$, then $N(u) \cap V\left(H^{\star}\right)=\left\{x, x_{3}, x_{4}\right\}$.

Lemma 4.2 $A \cup B \cup\left\{x, x_{1}, x_{2}, x_{3}, x_{4}\right\}$ is a cutset of $G$ that separates $N$ from $M$.
Proof. Assume not. Then $G \backslash\left(V\left(H^{\star}\right) \cup A \cup B\right)$ contains a chordless path $T=t_{1}, \ldots, t_{m}$ such that no vertex in $T \backslash\left\{t_{1}, t_{m}\right\}$ has a neighbor in $H^{\star} \backslash\left\{x, x_{1}, x_{2}, x_{3}, x_{4}\right\}, t_{1}$ has a neighbor in $N$ and $t_{m}$ has a neighbor in $M$. By Lemma 4.1, $m \geq 2, N\left(t_{1}\right) \cap V\left(H^{\star}\right) \subset N \cup\left\{x, x_{2}, x_{3}\right\}$ and $N\left(t_{m}\right) \cap V\left(H^{\star}\right) \subset M \cup\left\{x, x_{1}, x_{4}\right\}$. It suffices to consider the following two cases.

Case 1: $(H, x)$ is a line wheel, and hence Property 1 holds.
We have $N\left(t_{m}\right) \cap V\left(H^{\star}\right) \subset V\left(S_{4}\right)$. Let $u$ (resp. $v$ ) be the neighbor of $t_{m}$ in $S_{4}$ that is closest to $x_{1}$ (resp. $x_{4}$ ). By Lemma 4.1, either $u=v$ (and if that is the case, $u \notin\left\{x_{1}, x_{4}\right\}$ ) or $u v \in E(G)$.
(1) At least one of the sets $\left\{x_{1}, x_{2}\right\},\left\{x_{3}, x_{4}\right\}$ is anticomplete to $V(T) \backslash\left\{t_{1}, t_{m}\right\}$.

Proof of (1). Assume otherwise. Then there exists a minimal subpath $T^{t_{i} t_{j}}$ of $T \backslash\left\{t_{1}, t_{m}\right\}$ such that $t_{i}$ is adjacent to a vertex of $\left\{x_{1}, x_{2}\right\}$ and $t_{j}$ is adjacent to a vertex of $\left\{x_{3}, x_{4}\right\}$. Note that no interior vertex of $T^{t_{i} t_{j}}$ has a neighbor in $H$. Also, by Lemma 4.1, $i \neq j$. So, since $V\left(T^{t_{i} t_{j}}\right) \cup V(H)$ cannot induce a theta nor a pyramid, it follows that $N\left(t_{i}\right) \cap V(H)=\left\{x_{1}, x_{2}\right\}$ and $N\left(t_{j}\right) \cap V(H)=\left\{x_{3}, x_{4}\right\}$, and hence (by definition of $T$ ) neither $t_{i}$ nor $t_{j}$ is adjacent to $x$. But then $V\left(S_{4}\right) \cup V\left(T^{t_{i} t_{j}}\right) \cup\{x\}$ either induces a theta or a 1-wheel with center $x$, a contradiction.
(2) $x$ has a neighbor in $T \backslash\left\{t_{1}, t_{m}\right\}$.

Proof of (2). Assume not and let $R$ be the chordless $x_{1} t_{1}$-path contained in the graph induced by the $u x_{1}$-subpath of $S_{4}$ together with $V(T)$. First suppose that $t_{1}$ is adjacent to $x$, so that, by Lemma 4.1, $N\left(t_{1}\right) \cap N=\left\{p_{1}\right\}$. If $x_{2} t_{1}$ is not an edge, let $R^{\prime}$ be the chordless $x_{2} t_{1}$-path contained in the graph induced by the $u x_{2}$-subpath of $H \backslash\left\{x_{2}^{\prime}\right\}$ together with $V(T)$. Then $V\left(R^{\prime}\right) \cup\left\{p_{1}\right\}$ induces a hole $H^{\prime}$ and $\left(H^{\prime}, x\right)$ is a 3-wheel. So, $N\left(t_{1}\right) \cap V\left(H^{\star}\right)=\left\{x, x_{2}, p_{1}\right\}$. But then $V(R) \cup\left\{x, x_{2}\right\}$ induces a 3 -wheel with center $x_{2}$. It follows that $t_{1}$ is not adjacent to $x$. Let $D$ be the chordless $t_{1} p_{1}$-path contained in the graph induced by $N \cup\left\{t_{1}\right\}$. Then $V(R) \cup V(D) \cup\{x\}$ induces a hole $H^{\prime \prime}$ and $\left(H^{\prime \prime}, x_{2}\right)$ is a 3 -wheel, a contradiction.

By (2), let $t_{i}$ be the neighbor of $x$ in $T \backslash\left\{t_{1}, t_{m}\right\}$ with highest index.
(3) Either $x_{1}$ or $x_{4}$ is adjacent to $t_{i}$.

Proof of (3). Assume otherwise. If $x_{1}$ and $x_{4}$ have no neighbors in $T^{t_{i} t_{m-1}}$, then $V\left(S_{4}\right) \cup V\left(T^{t_{i} t_{m}}\right) \cup\{x\}$ either induces a theta or a pyramid. So, let $t_{j}$ be the vertex of $T^{t_{i+1} t_{m-1}}$ with highest index that has a neighbor in $\left\{x_{1}, x_{4}\right\}$. W.l.o.g. let $t_{j}$ be adjacent to $x_{1}$, and hence, by Lemma 4.1, not adjacent to $x_{4}$. Then it must be that either $u=x_{1}$ or $u=v=x_{1}^{\prime}$, since otherwise $V\left(S_{4}\right) \cup V\left(T^{t_{j} t_{m}}\right) \cup\{x\}$ induces a theta or a pyramid. Also, by (1), N( $\left.x_{4}\right) \cap V\left(T^{t_{i+1} t_{j-1}}\right)=\varnothing$. So, let $H^{\prime}$ be the hole induced by $\left(V\left(S_{4}\right) \backslash\left\{x_{1}\right\}\right) \cup V\left(T^{t_{i} t_{m}}\right) \cup\{x\}$. Then $\left(H^{\prime}, x_{1}\right)$ is a 1 -wheel, a contradiction.
(4) $x_{1}$ is adjacent to $t_{i}$.

Proof of (4). Assume not. Then, by (3), $t_{i}$ is adjacent to $x_{4}$ and hence, since $t_{i} \notin B$, not adjacent to $x_{3}$. By (1), $x_{1}$ and $x_{2}$ have no neighbors in the interior of $T$. Let $R$ be a chordless $x_{2} t_{1}$-path contained
in the graph induced by $N \cup\left\{x_{2}, t_{1}\right\}$. If $N\left(x_{4}\right) \cap V\left(T^{t_{2} t_{i-1}}\right) \neq \varnothing$, let $t_{j}$ be the neighbor of $x_{4}$ in $T^{t_{2} t_{i-1}}$ with lowest index. Then $t_{j}$ is adjacent to $x$, since otherwise $V\left(S_{4}\right) \cup V(R) \cup V\left(T^{t_{1} t_{j}}\right) \cup\{x\}$ induces a 1 -wheel with center $x$. So, $x_{3} t_{j}$ is not an edge. Now let $R^{\prime}$ be the chordless $x_{3} t_{j}$-path contained in the graph induced by $N \cup V\left(T^{t_{1} t_{j}}\right) \cup\left\{x_{3}\right\}$. It follows that $V\left(R^{\prime}\right) \cup\left\{x, x_{4}\right\}$ induces a 3 -wheel with center $x$, a contradiction. So, $N\left(x_{4}\right) \cap V\left(T^{t_{2} t_{i-1}}\right)=\varnothing$. If we denote by $D$ the chordless $x_{3} t_{i}$-path contained in the graph induced by $N \cup V\left(T^{t_{1} t_{i}}\right) \cup\left\{x_{3}\right\}$, then $V(D) \cup\left\{x_{4}\right\}$ induces a hole $H^{\prime}$ and $\left(H^{\prime}, x\right)$ is a 3 -wheel, a contradiction.
(5) $\left\{x_{3}, x_{4}\right\}$ is anticomplete to $V(T) \backslash\left\{t_{1}, t_{m}\right\}$.

Proof of (5). It follows from (1) and (4).
By (4), $t_{i}$ is adjacent to $x_{1}$. Since $t_{i} \notin A, t_{i}$ is not adjacent to $x_{2}$. Let $R$ be the chordless $x_{3} t_{1}$-path contained in the graph induced by $N \cup\left\{x_{3}, t_{1}\right\}$. If $N\left(x_{1}\right) \cap V\left(T^{t_{2} t_{i-1}}\right) \neq \varnothing$, let $t_{j}$ be the neighbor of $x_{1}$ in $T^{t_{2} t_{i-1}}$ with lowest index. Then $t_{j}$ is adjacent to $x$, since otherwise, by (5), $V\left(S_{4}\right) \cup V(R) \cup V\left(T^{t_{1} t_{j}}\right) \cup\{x\}$ induces a 1 -wheel with center $x$. So, $x_{2} t_{j}$ is not an edge. Now let $R^{\prime}$ be a chordless $x_{2} t_{j}$-path contained in the graph induced by $N \cup V\left(T^{t_{1} t_{j}}\right) \cup\left\{x_{2}\right\}$. It follows that $V\left(R^{\prime}\right) \cup\left\{x, x_{1}\right\}$ induces a 3 -wheel with center $x$, a contradiction. So, $x_{1}$ has no neighbors in $T^{t_{2} t_{i-1}}$. If we denote by $D$ a chordless $x_{2} t_{i}$-path contained in the graph induced by $N \cup V\left(T^{t_{1} t_{i}}\right) \cup\left\{x_{2}\right\}$, then $V(D) \cup\left\{x_{1}\right\}$ induces a hole $H^{\prime}$ and ( $\left.H^{\prime}, x\right)$ is a 3 -wheel, a contradiction.

Case 2: $(H, x)$ is a long alternating wheel.
First assume that $t_{1}$ has a neighbor in $N \backslash V(P)$, and let $u$ (resp. $v$ ) be the neighbor of $t_{1}$ in $S_{2}$ that is closest to $x_{2}$ (resp. $x_{3}$ ). By Lemma 4.1, $t_{1}$ is not adjacent to $x$.
(6) A vertex of $\left\{x_{2}, x_{3}\right\}$ has a neighbor in $T \backslash\left\{t_{1}, t_{m}\right\}$.

Proof of (6). Assume otherwise and let $R$ be a chordless $x t_{1}$-path contained in the graph induced by $M \cup V(T) \cup\{x\}$. If $u=v$, then $u \notin\left\{x_{2}, x_{3}\right\}$ and hence $V\left(S_{2}\right) \cup V(R)$ induces a $3 P C(x, u)$. So, by Lemma 4.1, $u v$ is an edge. But then the same vertex set induces a $3 P C\left(u v t_{1}, x\right)$, a contradiction.

By (6), let $t_{i}$ be the vertex of $T \backslash\left\{t_{1}, t_{m}\right\}$ with highest index that has a neighbor in $\left\{x_{2}, x_{3}\right\}$. W.l.o.g. let $t_{i}$ be adjacent to $x_{2}$. Then, by Lemma 4.1, $t_{i}$ is anticomplete to $\left\{x_{3}, x_{4}\right\}$.
(7) $t_{i}$ is adjacent to $x$.

Proof of (7). The graph induced by $\left(V(H) \backslash\left\{x_{1}\right\}\right) \cup V\left(T^{t_{i} t_{m}}\right)$ contains a hole $H^{\prime}$ that contains $x_{4}, V\left(S_{2}\right)$ and $t_{i}$. By Lemma 3.1, $\left(H^{\prime}, x\right)$ is an alternating wheel, and hence (7) holds.

By (7), Lemma 4.1 and definition of $T, N\left(t_{i}\right) \cap(V(H) \cup\{x\})=\left\{x, x_{2}\right\}$. Let $R$ be the chordless $x_{1} t_{i}$-path contained in the graph induced by $M \cup V\left(T^{t_{i} t_{m}}\right) \cup\left\{x_{1}\right\}$. By our choice of $t_{i}, V(R) \cup\left\{x_{2}\right\}$ induces a hole $H^{\prime}$ and $\left(H^{\prime}, x\right)$ is a 3 -wheel, a contradiction.
So, $N\left(t_{1}\right) \cap N \subseteq V(P)$. Let $p_{j}$ be the neighbor of $t_{1}$ in $P$ with highest index. Instead of $T$, consider the chordless path induced by $\left\{p_{k}, \ldots, p_{j}, t_{1}, \ldots, t_{m}\right\}$, and the arguments above still apply. This concludes the proof of Lemma 4.2.

## Attachments.

Let $u \in A \cup B$ and let $Q=q_{1}, \ldots, q_{r}$ be a chordless path in $G \backslash\left(V\left(H^{\star}\right) \cup A \cup B\right)$ such that $N(u) \cap V(Q)=$ $\left\{q_{1}\right\}$, no vertex in $Q \backslash\left\{q_{r}\right\}$ has a neighbor in $H^{\star} \backslash\left\{x, x_{1}, x_{2}, x_{3}, x_{4}\right\}$ and $q_{r}$ has a neighbor in $M$. Then we say that $Q$ is an attachment of $u$ to $M$. By Lemma 4.1, $N\left(q_{r}\right) \cap V\left(H^{\star}\right) \subset M \cup\left\{x, x_{1}, x_{4}\right\}$. Also, let $X_{1}^{\prime} \subseteq A$ (resp. $Y_{1}^{\prime} \subseteq B$ ) be the set of vertices in $A$ (resp. $B$ ) that have an attachment to $M$, and let $X_{1}=X_{1}^{\prime} \cup\left\{x_{1}\right\}\left(\right.$ resp. $\left.Y_{1}=Y_{1}^{\prime} \cup\left\{x_{4}\right\}\right)$.

Lemma 4.3 Let $u \in X_{1}^{\prime}$ and $Q=q_{1}, \ldots, q_{r}$ be an attachment of $u$ to $M$. Then the following hold:
(i) $x_{2}$ and $x_{3}$ have no neighbors in $Q$.
(ii) $x_{4}$ has no neighbors in $Q \backslash\left\{q_{r}\right\}$.

Proof. Let $v\left(\right.$ resp. $w$ ) be the neighbor of $q_{r}$ in $H \backslash V\left(S_{2}\right)$ that is closest to $x_{1}$ (resp. $x_{4}$ ). Since $N\left(q_{r}\right) \cap V\left(H^{\star}\right) \subset M \cup\left\{x, x_{1}, x_{4}\right\}$, the following hold.
(1) $q_{r}$ is anticomplete to $\left\{x_{2}, x_{3}\right\}$.
(2) $x_{3}$ and $x_{4}$ have no neighbors in $Q \backslash\left\{q_{r}\right\}$. In particular, (ii) holds.

Proof of (2). Assume otherwise. Let $q_{i}$ be the lowest indexed vertex of $Q \backslash\left\{q_{r}\right\}$ that has a neighbor in $\left\{x_{3}, x_{4}\right\}$ and let $R$ be the chordless $x_{2} q_{i}$-path contained in the graph induced by $V\left(Q^{q_{1} q_{i}}\right) \cup\left\{x_{2}, u\right\}$. First suppose that $q_{i}$ is adjacent to $x_{4}$. Then the graph induced by $\left(V(H) \backslash V\left(S_{2}\right)\right) \cup V\left(Q^{q_{1} q_{i}}\right) \cup\{u\}$ contains a hole $H^{\prime}$ that contains $V(H) \backslash V\left(S_{2}\right)$ and $q_{i}$. Also, by Lemma 3.1, $\left(H^{\prime}, x\right)$ is an alternating wheel. So, $q_{i}$ is adjacent to $x$. By definition of $Q, q_{i}$ is not adjacent to $x_{3}$. But then $V\left(S_{2}\right) \cup V(R) \cup\left\{x, x_{4}\right\}$ induces a 3 -wheel with center $x$. It follows that $q_{i}$ is adjacent to $x_{3}$ and not adjacent to $x_{4}$. Then $q_{i}$ is adjacent to $x$, since otherwise $V\left(S_{2}\right) \cup V(R) \cup\{x\}$ either induces a theta or a 1-wheel with center $x$. Furthermore, the graph induced by the vertex set $\left(V(H) \backslash V\left(S_{2}\right)\right) \cup V\left(Q^{q_{1} q_{i}}\right) \cup\left\{x_{3}, u\right\}$ contains a hole $H^{\prime \prime}$ that contains $V(H) \backslash V\left(S_{2}\right), x_{3}$ and $q_{i}$. But then $\left(H^{\prime \prime}, x\right)$ is a 3 -wheel, a contradiction.
(3) $x_{2}$ has no neighbors in $Q \backslash\left\{q_{r}\right\}$.

Proof of (3). Assume not and let $q_{i}$ be the highest indexed vertex of $Q \backslash\left\{q_{r}\right\}$ that is adjacent to $x_{2}$. Then $q_{i}$ must be adjacent to $x$, since otherwise, by (1) and (2), the $x_{2} w$-subpath of $H \backslash\left\{x_{1}\right\}$, together with $V\left(Q^{q_{i} q_{r}}\right) \cup\{x\}$, induces a 1 -wheel with center $x$. Let $R$ be the chordless $x_{1} q_{i}$-path contained in the graph induced by $V\left(Q^{q_{i} q_{r}}\right)$ together with the $x_{1} v$-subpath of $H \backslash\left\{x_{2}\right\}$. Since $q_{i} \notin A, q_{i}$ is not adjacent to $x_{1}$ and hence $V(R) \cup\left\{x_{2}\right\}$ induces a hole $H^{\prime}$ that contains $x_{1}, x_{2}$ and $q_{i}$, and $\left(H^{\prime}, x\right)$ is a 3 -wheel, a contradiction.

By (1), (2) and (3), (i) holds.
Analogous arguments prove Lemma 4.4.
Lemma 4.4 Let $u \in Y_{1}^{\prime}$ and $Q=q_{1}, \ldots, q_{r}$ be an attachment of $u$ to $M$. Then the following hold:
(i) $x_{2}$ and $x_{3}$ have no neighbors in $Q$.
(ii) $x_{1}$ has no neighbors in $Q \backslash\left\{q_{r}\right\}$.

Now let $u \in A \cup B$ be a vertex that is not special, and let $Q=q_{1}, \ldots, q_{r}$ be a chordless path in $G \backslash\left(V\left(H^{\star}\right) \cup A \cup B\right)$ such that $N(u) \cap V(Q)=\left\{q_{1}\right\}$, no vertex in $Q \backslash\left\{q_{r}\right\}$ has a neighbor in $H^{\star} \backslash$
$\left\{x, x_{1}, x_{2}, x_{3}, x_{4}\right\}$ and $q_{r}$ has a neighbor in $N$. Then we say that $Q$ is an attachment of $u$ to $N$. By Lemma 4.1, $N\left(q_{r}\right) \cap V\left(H^{\star}\right) \subset N \cup\left\{x, x_{2}, x_{3}\right\}$. Let $X_{2}^{\prime} \subseteq A$ be the set of vertices in $A$ that are either special or that have an attachment to $N$, let $Y_{2}^{\prime} \subseteq B$ be the set of vertices in $B$ that have an attachment to $N$, and let $X_{2}=X_{2}^{\prime} \cup\left\{x_{2}\right\}$ and $Y_{2}=Y_{2}^{\prime} \cup\left\{x_{3}\right\}$.

Lemma 4.5 Let $u \in X_{2}^{\prime}$ be a vertex that is not special and let $Q=q_{1}, \ldots, q_{r}$ be an attachment of $u$ to $N$. Then the following hold:
(i) $x_{1}$ and $x_{4}$ have no neighbors in $Q$.
(ii) $x_{3}$ has no neighbors in $Q \backslash\left\{q_{r}\right\}$.

Proof. Since $N\left(q_{r}\right) \cap V\left(H^{\star}\right) \subset N \cup\left\{x, x_{2}, x_{3}\right\}$, the following holds.
(1) $q_{r}$ is anticomplete to $\left\{x_{1}, x_{4}\right\}$.
(2) $x_{3}$ and $x_{4}$ have no neighbors in $Q \backslash\left\{q_{r}\right\}$. In particular, (ii) holds.

Proof of (2). Assume otherwise. Let $q_{i}$ be the lowest indexed vertex of $Q \backslash\left\{q_{r}\right\}$ that has a neighbor in $\left\{x_{3}, x_{4}\right\}$ and let $R$ be the chordless $x_{1} q_{i}$-path contained in the graph induced by $V\left(Q^{q_{1} q_{i}}\right) \cup\left\{x_{1}, u\right\}$. First suppose that $q_{i}$ is not adjacent to $x_{4}$, so $x_{3} q_{i} \in E(G)$. The graph induced by $V\left(S_{2}\right) \cup V\left(Q^{q_{1} q_{i}}\right) \cup\{u\}$ contains a hole $H^{\prime}$ that contains $V\left(S_{2}\right)$ and $q_{i}$. By Lemma 3.1, $\left(H^{\prime}, x\right)$ is an alternating wheel. So, $q_{i}$ is adjacent to $x$ and $\left(V(H) \backslash V\left(S_{2}\right)\right) \cup V(R) \cup\left\{x, x_{3}\right\}$ induces a 3 -wheel with center $x$, a contradiction. So, $x_{4} q_{i}$ is an edge. Then $q_{i}$ is adjacent to $x$, since otherwise $\left(V(H) \backslash V\left(S_{2}\right)\right) \cup V(R) \cup\{x\}$ induces a 1 -wheel with center $x$ or a theta. Since $q_{i} \notin B, q_{i}$ is not adjacent to $x_{3}$. Therefore the graph induced by $V\left(S_{2}\right) \cup V\left(Q^{q_{1} q_{i}}\right) \cup\left\{x_{4}, u\right\}$ contains a hole $H^{\prime \prime}$ that contains $V\left(S_{2}\right), x_{4}$ and $q_{i}$. But then $\left(H^{\prime \prime}, x\right)$ is a 3 -wheel, a contradiction.
(3) $x_{1}$ has no neighbors in $Q \backslash\left\{q_{r}\right\}$.

Proof of (3). Assume not and let $q_{i}$ be the highest indexed vertex of $Q \backslash\left\{q_{r}\right\}$ that is adjacent to $x_{1}$. First suppose that $q_{r}$ has a neighbor in the interior of $S_{2}$ and let $v$ (resp. $w$ ) be the neighbor of $q_{r}$ in $S_{2}$ that is closest to $x_{2}$ (resp. $x_{3}$ ). Then $q_{i}$ must be adjacent to $x$, since otherwise, by (1) and (2), the $x_{1} w$-subpath of $H \backslash\left\{x_{2}\right\}$, together with $V\left(Q^{q_{i} q_{r}}\right) \cup\{x\}$, induces a 1 -wheel with center $x$. Let $R$ be the chordless $x_{2} q_{i}$-path contained in the graph induced by $V\left(Q^{q_{i} q_{r}}\right)$ together with the $x_{2} v$-subpath of $H \backslash\left\{x_{1}\right\}$. Since $q_{i} \notin A, q_{i}$ is not adjacent to $x_{2}$ and hence $V(R) \cup\left\{x_{1}\right\}$ induces a hole $H^{\prime}$ that contains $x_{1}, x_{2}$ and $q_{i}$, and $\left(H^{\prime}, x\right)$ is a 3 -wheel, a contradiction. It follows that $q_{r}$ has no neighbors in the interior of $S_{2}$ and therefore $N\left(q_{r}\right) \cap V(P) \neq \varnothing$. Let $p_{j}$ be the neighbor of $q_{r}$ in $P$ with highest index and, by (1) and (2), let $H^{\prime \prime}$ be the hole induced by the $x_{2}^{\prime} x_{1}$-subpath of $H \backslash\left\{x_{2}\right\}$ together with $V\left(Q^{q_{i} q_{r}}\right) \cup V\left(P^{p_{j} p_{k}}\right)$. Then $x q_{i} \in E(G)$, since otherwise $\left(H^{\prime \prime}, x\right)$ is a 1-wheel. Since $q_{i}$ cannot be complete to $\left\{x, x_{1}, x_{2}\right\}$, then $q_{i}$ is not adjacent to $x_{2}$. Let $R^{\prime \prime}$ be the chordless $x_{2} q_{i}$-path contained in the graph induced by $V\left(Q^{q_{i} q_{r}}\right) \cup V\left(P^{p_{j} p_{k}}\right) \cup\left\{x_{2}\right\}$. Then $V\left(R^{\prime \prime}\right) \cup\left\{x, x_{1}\right\}$ induces a 3 -wheel with center $x$, a contradiction.

By (1), (2) and (3), (i) holds.
Analogous arguments prove Lemma 4.6.
Lemma 4.6 Let $u \in Y_{2}^{\prime}$ and $Q=q_{1}, \ldots, q_{r}$ be an attachment of $u$ to $N$. Then the following hold:
(i) $x_{1}$ and $x_{4}$ have no neighbors in $Q$.
(ii) $x_{2}$ has no neighbors in $Q \backslash\left\{q_{r}\right\}$.

Note that, by Lemma 4.1, $X_{i} \cap Y_{j}=\varnothing$ for every $1 \leq i, j \leq 2$. We also have the following.
Lemma 4.7 $X_{1} \cap X_{2}=Y_{1} \cap Y_{2}=\varnothing$.
Proof. Assume that $X_{1} \cap X_{2} \neq \varnothing$ and let $u \in A$ be a vertex that is not special and has an attachment $Q=q_{1}, \ldots, q_{r}$ to $N$ and an attachment $T=t_{1}, \ldots, t_{m}$ to $M$. By Lemma 4.2, $V(Q) \cap V(T)=\varnothing$ and $V(Q)$ is anticomplete to $V(T)$. Let $v$ be the neighbor of $t_{m}$ in $H \backslash V\left(S_{2}\right)$ that is closest to $x_{4}$. Suppose that $q_{r}$ has a neighbor in the interior of $S_{2}$ and let $w$ be the neighbor of $q_{r}$ in $S_{2}$ that is closest to $x_{3}$.
First assume that $x$ is not adjacent to $t_{1}$. By Lemma $4.5, x_{3}$ (resp. $x_{4}$ ) has no neighbors in $Q \backslash\left\{q_{r}\right\}$ (resp. $Q$ ), and, by Lemma 4.3, $x_{4}$ (resp. $x_{3}$ ) has no neighbors in $T \backslash\left\{t_{m}\right\}$ (resp. $T$ ). So the $v w$-subpath of $H \backslash V\left(S_{1}\right)$, together with $V(Q) \cup V(T) \cup\{u\}$, induces a hole $H^{\prime}$ that contains $x_{3}, x_{4}$ and $u$. By Lemma 3.1, $\left(H^{\prime}, x\right)$ is an alternating wheel and hence $x$ is adjacent to $q_{1}$. By Lemma $4.5, x_{1}$ has no neighbors in $Q$, and therefore the $x_{1} w$-subpath of $H \backslash\left\{x_{2}\right\}$, together with $V(Q) \cup\{x, u\}$, induces a 3-wheel with center $x$, a contradiction. So, $x t_{1}$ is an edge. By Lemma 4.3, $x_{2}$ has no neighbors in $T$. It follows that the $x_{2} v$-subpath of $H \backslash\left\{x_{1}\right\}$, together with $V(T) \cup\{x, u\}$, induces a 3 -wheel with center $x$, a contradiction. It follows that $q_{r}$ has no neighbors in the interior of $S_{2}$ but has a neighbor in $P$. Instead of $Q$, consider now the chordless $p_{k} q_{1}$-path contained in the graph induced by $V\left(Q^{q_{1} q_{r}}\right) \cup V(P)$, and the arguments above still apply. The same approach works when $u$ is a special vertex. This proves that $X_{1} \cap X_{2}=\varnothing$. Analogously, it can be shown that $Y_{1} \cap Y_{2}=\varnothing$.

Lemma $4.8 X_{1}, X_{2}, Y_{1}$ and $Y_{2}$ are all cliques of $G$.
Proof. Suppose that $u, v \in X_{1}, u \neq v$ and $u v$ is not an edge, and let $Q$ (resp. $T$ ) be an attachment of $u$ (resp. $v$ ) to $M$. Let $R$ be a chordless $u v$-path contained in the graph induced by $M \cup V(Q) \cup V(T) \cup\{u, v\}$. By Lemma 4.3, $V(R) \cup\left\{x_{2}\right\}$ induces a hole $H^{\prime}$ and hence $\left(H^{\prime}, x\right)$ is a 3 -wheel, a contradiction. So, $X_{1}$ is a clique. Analogous arguments show that $X_{2}, Y_{1}$ and $Y_{2}$ are cliques too.

## Ears.

Let $T=t_{1}, \ldots, t_{m}$ be a chordless path in $G \backslash\left(V\left(H^{\star}\right) \cup A \cup B\right)$ such that $N\left(t_{i}\right) \cap\left(V\left(H^{\star}\right) \backslash\left\{x, x_{1}, x_{2}, x_{3}, x_{4}\right\}\right)=$ $\varnothing$, for every $1 \leq i \leq m$, and let $u \in A$ and $v \in B$ be such that $N(u) \cap V(T)=\left\{t_{1}\right\}$ and $N(v) \cap V(T)=\left\{t_{m}\right\}$. Then we say that $T$ is an ear of $H^{\star}$, while $u$ and $v$ are said to be the attachments of $T$. Let $X_{3}$ (resp. $Y_{3}$ ) be the set of vertices of $A \backslash\left(X_{1} \cup X_{2}\right)$ (resp. $\left.B \backslash\left(Y_{1} \cup Y_{2}\right)\right)$ that are attachments of an ear of $H^{\star}$.

Lemma 4.9 If $T=t_{1}, \ldots, t_{m}$ is an ear of $H^{\star}$, then $N\left(t_{i}\right) \cap V(H)=\varnothing$ for every $1 \leq i \leq m$.

Proof. By definition, $N\left(t_{i}\right) \cap V(H) \subseteq\left\{x_{1}, x_{2}, x_{3}, x_{4}\right\}$ for every $1 \leq i \leq m$. We now show that $t_{i}$ is anticomplete to $\left\{x_{1}, x_{2}\right\}$ for every $1 \leq i \leq m$. Assume otherwise and let $t_{j}$ be the vertex of $T$ with highest index that is adjacent to a vertex of $\left\{x_{1}, x_{2}\right\}$, and let $u \in A$ and $v \in B$ be the attachments of $T$. By Lemma 4.1, $t_{j}$ is anticomplete to $\left\{x_{3}, x_{4}\right\}$. Furthermore, let $R$ (resp. $R^{\prime}$ ) be the chordless $t_{j} x_{4}$-path (resp. $t_{j} x_{3}$-path) contained in the graph induced by $V\left(T^{t_{j} t_{m}}\right) \cup\left\{x_{4}, v\right\}$ (resp. $V\left(T^{t_{j} t_{m}}\right) \cup\left\{x_{3}, v\right\}$ ). First suppose that $t_{j} x_{1}$ is an edge, and let $H^{\prime}$ be the hole induced by the $x_{1} x_{4}$-subpath of $H \backslash\left\{x_{2}\right\}$ together
with $R$. Then by Lemma 3.1, $\left(H^{\prime}, x\right)$ is an alternating wheel, and hence $t_{j}$ is adjacent to $x$. Since $t_{j} \notin A$, it follows that $t_{j}$ is not adjacent to $x_{2}$. Now let $H^{\prime \prime}$ be the hole induced by $V\left(S_{2}\right) \cup V\left(R^{\prime}\right) \cup\left\{x_{1}\right\}$. Then $\left(H^{\prime \prime}, x\right)$ is a 3 -wheel, a contradiction. Hence, $t_{j}$ is adjacent to $x_{2}$ and not adjacent to $x_{1}$. Also, $t_{j}$ is adjacent to $x$, since otherwise $V\left(S_{2}\right) \cup V\left(R^{\prime}\right) \cup\{x\}$ either induces a theta or a 1 -wheel with center $x$. Therefore the $x_{2} x_{4}$-subpath of $H \backslash\left\{x_{3}\right\}$, together with $V(R) \cup\{x\}$, induces a 3 -wheel with center $x$, a contradiction. So $t_{i}$ is anticomplete to $\left\{x_{1}, x_{2}\right\}$ for every $1 \leq i \leq m$. Analogously it can be shown that $t_{i}$ is also anticomplete to $\left\{x_{3}, x_{4}\right\}$ for every $1 \leq i \leq m$.

Lemma $4.10 X_{3}\left(\right.$ resp. $\left.Y_{3}\right)$ is a clique of $G$ that is complete to $X_{1} \cup X_{2}\left(\right.$ resp. $\left.Y_{1} \cup Y_{2}\right)$.

Proof. We only prove that $X_{3}$ is a clique of $G$ and that it is complete to $X_{1} \cup X_{2}$, since similar arguments show that $Y_{3}$ is a clique of $G$ that is complete to $Y_{1} \cup Y_{2}$.
(1) $X_{3}$ is a clique of $G$.

Proof of (1). Assume not and let $u, v \in X_{3}, u \neq v$, be such that $u v \notin E(G)$. Let $T=t_{1}, \ldots, t_{m}$ (resp. $\left.D=d_{1}, \ldots, d_{h}\right)$ be an ear of $H^{\star}$ with attachments $u \in A$ and $w \in B$ (resp. $v \in A$ and $z \in B$ ). Let $R$ be a chordless $u v$-path contained in the graph induced by $V(T) \cup V(D) \cup\left\{x_{3}, u, v, w, z\right\}$. By Lemma 4.9, $V(R) \cup\left\{x_{1}\right\}$ induces a hole $H^{\prime}$, and $\left(H^{\prime}, x\right)$ is a 3 -wheel, a contradiction.
(2) $X_{3}$ is complete to $X_{1} \cup X_{2}$.

Proof of (2). Assume that $X_{3}$ is not complete to $X_{2}$. Let $u \in X_{3}$ and $v \in X_{2}$ ( $v$ not special), be such that $u v \notin E(G)$. Let $Q$ be an attachment of $v$ to $N$ and let $T$ be an ear of $H^{\star}$ with attachments $u \in A$ and $w \in B$. Let $R$ be a chordless $u v$-path contained in the graph induced by $N \cup V(Q) \cup V(T) \cup\left\{u, v, w, x_{3}\right\}$. By Lemma 4.5 and Lemma 4.9, $V(R) \cup\left\{x_{1}\right\}$ induces a hole $H^{\prime}$. But then $\left(H^{\prime}, x\right)$ is a 3 -wheel, a contradiction. A similar argument applies when $v$ is special. So $X_{3}$ is complete to $X_{2}$. Analogously, it can be shown that $X_{3}$ is also complete to $X_{1}$.

This proves the lemma.
Let $X=X_{1} \cup X_{2} \cup X_{3}$ and $Y=Y_{1} \cup Y_{2} \cup Y_{3}$.
Lemma $4.11 X$ and $Y$ are disjoint and anticomplete.

Proof. Sets $X$ and $Y$ are disjoint by Lemma 4.1. Suppose that $u \in X$ and $v \in Y$ are such that $u v$ is an edge. Then $V\left(S_{2}\right) \cup\{x, u, v\}$ induces a 3 -wheel with center $x$, a contradiction. So, $X$ and $Y$ are anticomplete to each other.

## Putting things together.

We are ready to conclude the proof of Theorem 1.12. Let $S=\{x\} \cup X \cup Y$.
Lemma 4.12 $S$ is a cutset of $G$ that separates $N$ from $M$.

Proof. Suppose that $S$ is not a cutset of $G$ that separates $N$ from $M$. Then there exists a path $Q=q_{1}, \ldots, q_{r}$ in $G \backslash S$, such that $q_{1}\left(\right.$ resp. $\left.q_{r}\right)$ has a neighbor in $N$ (resp. $M$ ), and let $Q$ be chosen such
that it has the shortest length. It follows that $Q$ is chordless and no vertex of $Q \backslash\left\{q_{1}, q_{r}\right\}$ has a neighbor in $H^{\star} \backslash\left\{x, x_{1}, x_{2}, x_{3}, x_{4}\right\}$. By Lemma $4.2, V(Q) \cap(A \cup B) \neq \varnothing$. So, let $q_{i}$ be the vertex of $V(Q) \cap(A \cup B)$ with the lowest index, and w.l.o.g. assume that $q_{i} \in A$. But then either $i=1$ and $q_{1}$ is special, or $i>1$ and $Q^{q_{1} q_{i-1}}$ is an attachment of $q_{i}$ to $N$, and hence $q_{i} \in X_{2}$, a contradiction.

Let $\mathcal{C}^{*}$ be the set of all connected components of $G \backslash S$. The sets $C_{1}, C_{2}, C_{3}, C_{X}, C_{Y}$ are defined as follows:

- $C_{1}$ (resp. $C_{2}$ ) is the vertex set of the connected component from $\mathcal{C}^{*}$ that contains $M$ (resp. $N$ );
- $C_{X}$ (resp. $C_{Y}$ ) is the union of vertex sets of all $C \in \mathcal{C}^{*}$, such that $N(C) \subseteq\{x\} \cup X$ (resp. $N(C) \subseteq$ $\{x\} \cup Y) ;$
- $C_{3}$ is the union of vertex sets of all $C \in \mathcal{C}^{*}$ such that $V(C) \nsubseteq C_{1} \cup C_{2} \cup C_{X} \cup C_{Y}$.

Lemma 4.13 $C_{X} \cap C_{Y}=\varnothing$.

Proof. Assume otherwise. Then $C_{X}$ and $C_{Y}$ are both non-empty and such that $N\left(C_{X}\right) \subseteq\{x\}$ and $N\left(C_{Y}\right) \subseteq\{x\}$. But then $G$ admits a clique cutset, a contradiction.

Lemma 4.14 If $C \in \mathcal{C}^{*}$ is such that $V(C) \nsubseteq C_{1} \cup C_{X} \cup C_{Y}$, then $x_{1}$ and $x_{4}$ have no neighbors in $C$.

Proof. Consider first the following claim.
(1) $x_{1}$ and $x_{4}$ have no neighbors in $C_{2}$.

Proof of (1). Assume otherwise and let $Q=q_{1}, \ldots, q_{r}$ be a shortest path in $G\left[C_{2} \backslash N\right]$ such that $q_{1}$ (resp. $q_{r}$ ) has a neighbor in $\left\{x_{1}, x_{4}\right\}$ (resp. $N$ ). Note that (since $q_{i} \notin S$ for every $\left.1 \leq i \leq r\right) q_{r}$ is not special, and hence by Lemma 4.1, $r \geq 2$. By minimality of $Q, Q$ is chordless, no vertex of $Q \backslash\left\{q_{1}\right\}$ is adjacent to $x_{1}$ or $x_{4}$, and no vertex of $Q \backslash\left\{q_{r}\right\}$ has a neighbor in $N$. Also, by Lemma 4.12, no vertex of $Q$ has a neighbor in $M$.
W.l.o.g. suppose $x_{1} q_{1} \in E(G)$. Then, by our choice of $Q$ and Lemma 4.1, $x_{4}$ is anticomplete to $V(Q)$. Let $R$ be the chordless $x_{3} q_{1}$-path contained in the graph induced by $V(Q) \cup N \cup\left\{x_{3}\right\}$. Then the $x_{1} x_{3}$ subpath of $H \backslash\left\{x_{2}\right\}$, together with $V(R) \cup\{x\}$, induces a 1-wheel with center $x$, unless $x$ is adjacent to $q_{1}$. So, $x q_{1} \in E(G)$. If $x_{2} q_{1}$ is an edge, then $Q^{q_{2} q_{r}}$ is an attachment of $q_{1}$ to $N$, and hence $q_{1} \in X_{2}$, a contradiction. So, $x_{2} q_{1}$ is not an edge. Now let $R^{\prime}$ be a chordless $x_{2} q_{1}$-path contained in the graph induced by $V(Q) \cup N \cup\left\{x_{2}\right\}$. Then $V\left(R^{\prime}\right) \cup\left\{x_{1}\right\}$ induces a hole $H^{\prime}$ and $\left(H^{\prime}, x\right)$ is a 3 -wheel, a contradiction.

By (1), w.l.o.g. we may assume that $x_{1}$ has a neighbor in $C^{\prime} \in \mathcal{C}^{*}$ such that $V\left(C^{\prime}\right) \nsubseteq C_{1} \cup C_{2} \cup C_{X} \cup C_{Y}$. So, $C^{\prime}$ contains a chordless path $T=t_{1}, \ldots, t_{m}$ such that $t_{1}$ is adjacent to $x_{1}, t_{m}$ is adjacent to a vertex of $Y$ and $N\left(t_{i}\right) \cap V\left(H^{\star}\right) \subseteq\left\{x, x_{1}, x_{2}, x_{3}, x_{4}\right\}$ for every $1 \leq i \leq m$. Pick such a path of minimum length. Then no vertex of $T \backslash\left\{t_{1}\right\}$ is adjacent to $x_{1}$ and no vertex of $T \backslash\left\{t_{m}\right\}$ has a neighbor in $Y$.
(2) $t_{m}$ is anticomplete to $\left\{x_{3}, x_{4}\right\}$.

Proof of (2). Assume otherwise and let $H^{\prime}$ be the hole induced by $\left(V(H) \backslash V\left(S_{2}\right)\right) \cup V(T)$, together with $x_{3}$ if $t_{m}$ is not adjacent to $x_{4}$. By Lemma 3.1, $\left(H^{\prime}, x\right)$ is an alternating wheel. It follows that $t_{1}$ is adjacent to $x$. Suppose that $x_{2} t_{1} \notin E(G)$, and let $R$ be the chordless $x_{2} t_{1}$-path contained in the graph induced by $V\left(S_{2}\right) \cup V(T)$, together with $x_{4}$ if $t_{m}$ is not adjacent to $x_{3}$. Then $V(R) \cup\left\{x_{1}\right\}$ induces a
hole $H^{\prime \prime}$ and $\left(H^{\prime \prime}, x\right)$ is a 3 -wheel, a contradiction. So, $x_{2} t_{1} \in E(G)$. Let $R^{\prime}$ be the chordless $x_{2} t_{m}$-path contained in $G\left[V(T) \cup\left\{x_{2}\right\}\right]$. First suppose that $t_{m}$ is adjacent to $x_{3}$. Then $x t_{m}$ is an edge, since otherwise $V\left(S_{2}\right) \cup V\left(R^{\prime}\right) \cup\{x\}$ induces a theta or a 1-wheel with center $x$. Also, if $x_{4} t_{m} \notin E(G)$, then $\left(H^{\prime}, x\right)$ is a 3 -wheel. It follows that $x_{3} t_{m} \in E(G)$, and hence $m>2$, since otherwise $\left(H^{\prime}, x\right)$ is a 3 -wheel. But then $T^{t_{2} t_{m-1}}$ is an ear of $H^{\star}$ with attachments $t_{1}$ and $t_{m}$, implying that $t_{1} \in X$ and $t_{m} \in Y$, a contradiction. So $x_{3} t_{m} \notin E(G)$ and $x_{4} t_{m} \in E(G)$. Since $\left(H^{\prime}, x\right)$ is an alternating wheel, $x t_{m} \in E(G)$. But then $V\left(S_{2}\right) \cup V\left(R^{\prime}\right) \cup\left\{x, x_{4}\right\}$ induces a 3 -wheel with center $x$, a contradiction.

By (2), $t_{m}$ has a neighbor $u \in Y \backslash\left\{x_{3}, x_{4}\right\}$. Note that $x t_{1}$ is an edge, since otherwise $\left(V(H) \backslash V\left(S_{2}\right)\right) \cup$ $V(T) \cup\{x, u\}$ induces a 1 -wheel with center $x$. If $m=1$ then $\left(V(H) \backslash V\left(S_{2}\right)\right) \cup\left\{u, t_{1}\right\}$ induces a hole $H^{\prime}$ and $\left(H^{\prime}, x\right)$ is a 3 -wheel. So $m \geq 2$. If $x_{2}$ is adjacent to $t_{1}$, then $T^{t_{2} t_{m}}$ is an ear of $H^{\star}$, and hence $t_{1} \in X$, a contradiction. So, $t_{1}$ is not adjacent to $x_{2}$. If $R$ denotes the chordless $x_{2} t_{1}$-path contained in the graph induced by $V\left(S_{2}\right) \cup V(T) \cup\{u\}$, then $V(R) \cup\left\{x, x_{1}\right\}$ induces a 3 -wheel with center $x$, a contradiction.
Analogous arguments prove the following lemma.
Lemma 4.15 If $C \in \mathcal{C}^{*}$ is such that $V(C) \nsubseteq C_{X} \cup C_{Y} \cup C_{2}$, then $x_{2}$ and $x_{3}$ have no neighbors in $C$.
Lemma 4.16 $X \backslash X_{i}$ and $Y \backslash Y_{i}$ are anticomplete to $C_{i}$, for $1 \leq i \leq 2$.
Proof. Suppose that $u \in X \backslash\left(X_{1} \cup\left\{x_{2}\right\}\right)$ has a neighbor in $C_{1}$. It follows that $G\left[C_{1} \backslash M\right]$ contains a chordless path $Q=q_{1}, \ldots, q_{r}$ such that $q_{1}$ is adjacent to $u$ and $q_{r}$ has a neighbor in $M$. By Lemma 4.12, no vertex of $Q$ has a neighbor in $N$. Also, if we choose $Q$ to be of shortest length, then no vertex of $Q \backslash\left\{q_{1}\right\}$ is adjacent to $u$ and no vertex of $Q \backslash\left\{q_{r}\right\}$ has a neighbor in $M$. So, since $u \notin X_{1}$ and hence $Q$ is not an attachment of $u$ to $M, V(Q) \cap(A \cup B) \neq \varnothing$, contradicting Lemma 4.15. It follows that $X \backslash X_{1}$ is anticomplete to $C_{1}$. Similar arguments show that $Y \backslash Y_{1}$ is anticomplete to $C_{1}$, and that $X \backslash X_{2}$ and $Y \backslash Y_{2}$ are anticomplete to $C_{2}$.

Lemma $4.17 X_{i}$ and $Y_{i}$ are anticomplete to $C_{3}$, for $1 \leq i \leq 2$.
Proof. By Lemma 4.14 and Lemma 4.15, $\left\{x_{1}, x_{2}, x_{3}, x_{4}\right\}$ is anticomplete to $C_{3}$. Suppose that $u \in$ $X_{1} \backslash\left\{x_{1}\right\}$ has a neighbor in $C_{3}$. Then $C_{3}$ contains a chordless path $T=t_{1}, \ldots, t_{m}$, such that $t_{1}$ is adjacent to $u, t_{m}$ is adjacent to a vertex $v \in Y \backslash\left\{x_{3}, x_{4}\right\}$ and $N\left(t_{i}\right) \cap V\left(H^{\star}\right) \subseteq\{x\}$, for every $1 \leq i \leq m$. Pick such a path of minimum length. Then no vertex of $T \backslash\left\{t_{1}\right\}$ is adjacent to $x_{1}$ and no vertex of $T \backslash\left\{t_{m}\right\}$ has a neighbor in $Y \backslash\left\{x_{3}, x_{4}\right\}$. Note that $T$ is an ear of $H^{\star}$, with attachments $u$ and $v$. By Lemma 4.11, $u v$ is not an edge. Let $D=d_{1}, \ldots, d_{h}$ be an attachment of $u$ to $M$. Since $T$ and $D$ belong to different connected components of $G \backslash S, V(T) \cap V(D)=\varnothing$ and $V(T)$ is anticomplete to $V(D)$. Also, $V(D) \cap\{v\}=\varnothing$. Now let $R$ be the chordless $u v$-path contained in the graph induced by $M \cup V(D) \cup\left\{u, v, x_{4}\right\}$. Then $V(R) \cup V(T)$ induces a hole $H^{\prime}$ and, by Lemma 3.1, $\left(H^{\prime}, x\right)$ is an alternating wheel. If $x$ is adjacent to $d_{1}$ (note that $x_{3} u$ is not an edge by Lemma 4.1), let $R^{\prime}$ be the chordless $x_{3} u$-path contained in the graph induced by $M \cup V(D) \cup\left\{u, x_{3}, x_{4}\right\}$. Then, by Lemma 4.3, $V\left(R^{\prime}\right) \cup V\left(S_{2}\right)$ induces a hole $H^{\prime \prime}$, and $\left(H^{\prime \prime}, x\right)$ is a 3 -wheel, a contradiction. Hence, $x$ is adjacent to $t_{1}$. But then $V\left(S_{2}\right) \cup V(T) \cup\{x, u, v\}$ induces a 3 -wheel with center $x$, a contradiction. Therefore $X_{1}$ is anticomplete to $C_{3}$ and, similarly, so is $Y_{1}$. Analogous arguments show that $X_{2} \cup Y_{2}$ is anticomplete to $C_{3}$.

Proof of Theorem 1.12. By definitions, Lemma 4.7, Lemma 4.11, Lemma 4.12 and Lemma 4.13, $\mathcal{S}=\left(\{x\}, X_{1}, X_{2}, X_{3}, Y_{1}, Y_{2}, Y_{3}, C_{1}, C_{2}, C_{X}, C_{Y}\right)$ is a partition of $V(G)$. Also, if we set $y_{1}=x_{4}$ and
$y_{2}=x_{3}, \mathcal{S}$ satisfies (i) by the definition of sets $X_{i}, Y_{i}$ and $C_{i}$, for $1 \leq i \leq 2$, and $X_{3}, Y_{3}$. By Lemma 4.11, $X$ is anticomplete to $Y$, by Lemma 4.16 and Lemma $4.17, X_{i} \cup Y_{i}$ is anticomplete to $C_{j}$ if $i \neq j$, and by definitions, $x$ is complete to $X \cup Y$ and a vertex from $X_{i} \cup Y_{i}$ has a neighbor in $C_{i}$, for $1 \leq i \leq 3$. So, $\mathcal{S}$ satisfies (ii). By Lemma 4.8 and Lemma $4.10, \mathcal{S}$ satisfies (iii). Finally, properties (iv) and (v) follow from definitions of sets $C_{1}, C_{2}, C_{3}, C_{X}$ and $C_{Y}$, and Lemma 4.12. So $G$ is structured.

### 4.1 Proof of Theorem 1.11

In this subsection we prove Theorem 1.11, so we further assume that $G \in \mathcal{C}$ does not contain a wheel with an appendix. By Theorem 1.10, it is enough to consider the case when $G$ contains a long alternating wheel, i.e. we may assume that $G$ satisfies Property 2 . So we keep the same notation as before, and prove that the structured partition $\mathcal{S}$ of $G$, obtained in Theorem 1.12, has some additional properties (under the assumption that $G$ does not admit a clique cutset).

Lemma 4.18 Let $u \in X_{2}^{\prime}$ and $Q=q_{1}, \ldots, q_{r}$ be an attachment of $u$ to $N$. Then:
(1) $x$ is anticomplete to $V(Q)$;
(2) if $x_{2}$ is not adjacent to $q_{r}$, then it is anticomplete to $V(Q)$.

Proof. (1) Assume not. Let $q_{i}$ be the highest indexed vertex of $Q$ that is adjacent to $x$ and let $v$ be the neighbor of $q_{r}$ in $S_{2}$ that is closest to $x_{3}$. By Lemma $4.1 x$ is not adjacent to $q_{r}$, and hence $i<r$.
First suppose $x_{2} v \notin E(G)$. Then, by Lemma 4.1, $x_{2}$ is not adjacent to $q_{r}$, and $x_{2}$ must have a neighbor in $Q^{q_{i} q_{r-1}}$, since otherwise, by Lemma 4.1 and Lemma $4.5, V\left(S_{2}\right) \cup V\left(Q^{q_{i} q_{r}}\right) \cup\{x\}$ induces a theta or a pyramid. If $x_{2}$ has a neighbor in $Q^{q_{i+1} q_{r-1}}$, then the graph induced by $V\left(S_{2}\right) \cup V\left(Q^{q_{i+1} q_{r}}\right) \cup\{x\}$ contains a theta or a pyramid. So, $N\left(x_{2}\right) \cap V\left(Q^{q_{i} q_{r}}\right)=\left\{q_{i}\right\}$. By Lemma 4.5, the $v x_{1}$-subpath of $H \backslash\left\{x_{2}\right\}$, together with $V\left(Q^{q_{i} q_{r}}\right) \cup\left\{x, x_{2}\right\}$, induces a 3 -wheel with center $x$, a contradiction. It follows that $x_{2} v \in E(G)$. By Lemma 4.5, the $v x_{3}$-subpath of $S_{2}$, together with $V\left(Q^{q_{i} q_{r}}\right) \cup\{x\}$, induces a hole $H^{\prime}$, and, by Lemma 3.1, $\left(H^{\prime}, x_{2}\right)$ is an alternating wheel. So, $i<r-1$ and $x_{2}$ is adjacent to $q_{i}$ and $q_{r}$. But then, by Lemma 4.5, $Q^{q_{i} q_{r}}$ is an appendix of $(H, x)$, a contradiction.
(2) Assume not. Let $q_{i}$ be the highest indexed vertex of $Q$ that is adjacent to $x_{2}$ and let $v$ be the neighbor of $q_{r}$ in $S_{2}$ that is closest to $x_{3}$. By Lemma 4.5 and (1), the $v x_{3}$-subpath of $S_{2}$ together with $V(Q) \cup\{x, u\}$ induces a hole $H^{\prime}$, and therefore $x_{2} v$ is not an edge, since otherwise $\left(H^{\prime}, x_{2}\right)$ is a 1 -wheel. Now, by Lemma 4.1, Lemma 4.5 and $(1), V\left(S_{2}\right) \cup V\left(Q^{q_{i} q_{r}}\right) \cup\{x\}$ induces a theta or a pyramid, a contradiction.

Lemma 4.19 $X_{1}\left(\right.$ resp. $\left.Y_{1}\right)$ is complete to $X_{2}\left(\right.$ resp. $\left.Y_{2}\right)$.

Proof. Let $u \in X_{1}$ and $v \in X_{2}$, and suppose that $u v$ is not an edge. Let $Q=q_{1}, \ldots, q_{r}$ (resp. $T=t_{1}, \ldots, t_{m}$ ) be an attachment of $v$ (resp. $u$ ) to $N$ (resp. $M$ ). By Lemma 4.2, $V(Q) \cap V(T)=\varnothing$ and $V(Q)$ is anticomplete to $V(T)$.
Denote by $w$ (resp. $z$ ) the neighbor of $q_{r}$ (resp. $t_{m}$ ) in $S_{2}$ (resp. $V(H) \backslash V\left(S_{2}\right)$ ) that is closest to $x_{3}$ (resp. $x_{4}$ ). First suppose $x_{2} w \in E(G)$. It follows that $r>1$ and $q_{r}$ is adjacent to $x_{2}$ since otherwise, by Lemma 4.5 and Lemma 4.18, the vertex set $V\left(S_{2}\right) \cup V(Q) \cup\{x, v\}$ induces a 1 -wheel or a 3 -wheel with center $x_{2}$. By Lemma 4.3, the $x_{2} z$-subpath of $H \backslash\left\{x_{1}\right\}$, together with $V(T) \cup\{u\}$, induces a hole $H^{\prime}$ and, by Lemma 3.1, $\left(H^{\prime}, x\right)$ is an alternating wheel. Furthermore, by Lemma 4.5 and Lemma 4.18, the chordless
path induced by $V(Q) \cup\{v\}$ is an appendix of $\left(H^{\prime}, x\right)$, a contradiction. Therefore $x_{2} w$ is not an edge, and hence, by Lemma 4.1, $x_{2}$ is not adjacent to $q_{r}$. But then by Lemma 4.3, Lemma 4.5 and Lemma 4.18, the $w z$-subpath of $H \backslash\left\{x_{1}\right\}$, together with $V(Q) \cup V(T) \cup\left\{x_{2}, u, v\right\}$, induces a hole $H^{\prime \prime}$, and $\left(H^{\prime \prime}, x\right)$ is a 3 -wheel, a contradiction. So $X_{1}$ is complete to $X_{2}$, and by symmetry $Y_{1}$ is complete to $Y_{2}$.

Proof of Theorem 1.11. Let $K=\{x\}, W_{1}=X_{1}, Z_{1}=Y_{1}, W_{2}=X_{2} \cup X_{3}, Z_{2}=Y_{2} \cup Y_{3}, V_{1}=$ $W_{1} \cup Z_{1} \cup C_{1}$ and $V_{2}=W_{2} \cup Z_{2} \cup C_{2} \cup C_{3}$. We now show that, if $G$ does not admit a clique cutset, then $\left(K, V_{1}, V_{2}\right)$ is a special 2-amalgam of $G$. By Lemma 4.8, Lemma 4.10, and Lemma 4.19, the sets $X_{1} \cup X_{2} \cup X_{3}$ and $Y_{1} \cup Y_{2} \cup Y_{3}$ are cliques, and hence so are the sets $N\left(C_{X}\right)$ and $N\left(C_{Y}\right)$. So, by our assumptions, $C_{X}=C_{Y}=\varnothing$, and hence $\left(K, V_{1}, V_{2}\right)$ is a special 2-amalgam of $G$.

### 4.2 Proof of Lemma 4.1

We prove Lemma 4.1 by considering Property 1 and Property 2 separately.
The following simple result will be used throughout.
Lemma 4.20 Let $(H, x)$ be an alternating wheel of a graph $G \in \mathcal{C}$, and let $y \in V(G) \backslash(V(H) \cup\{x\})$ be adjacent to $x$. If $u$ and $v$ are consecutive neighbors of $y$ in $H$, then they cannot belong to the interior of two different long sectors of $(H, x)$.

Proof. Otherwise the $u v$-subpath of $H$ that does not contain any other neighbor of $y$ in $H$, together with $\{x, y\}$, induces a 1 -wheel with center $x$.

## Property 1 holds.

We first assume that $G$ satisfies Property 1. The wheel $(H, x)$, its appendix $P$ and other associated notation are as in the beginning of Section 4. Let $y$ be a vertex of $G \backslash(V(H) \cup V(P) \cup\{x\})$. We also use the following notation in this part: $N=V\left(S_{2}\right) \backslash\left\{x_{2}, x_{3}\right\}, M=V(H) \backslash\left(V\left(S_{2}\right) \cup\left\{x_{1}, x_{4}\right\}\right)$ and $N^{\prime}=N \cup V(P)$.

Lemma 4.21 If $y$ is adjacent to $x$ and not adjacent to $p_{1}$, then $N(y) \cap V(P)=\varnothing$.
Proof. Assume otherwise and let $p_{i}$ be the neighbor of $y$ in $P$ with lowest index. If $y$ is adjacent to $x_{2}$, then $V\left(P^{p_{1} p_{i}}\right) \cup\left\{x, x_{2}, y\right\}$ induces a 3 -wheel with center $x_{2}$. So, $x_{2} y$ is not an edge. By Lemma 3.1, $(W, y)$ is an alternating wheel, and so $y$ is adjacent to $x_{3}$. If $i=k$, then $y$ is also adjacent to $x_{2}^{\prime}$ and hence $\left\{x, x_{2}, x_{2}^{\prime}, y, p_{k}\right\}$ induces a 3 -wheel with center $p_{k}$. So, $i<k$. Let $y^{\prime}$ be the neighbor of $y$ in $S_{2}$ that is closest to $x_{2}$ and let $R$ be the $x_{2} y^{\prime}$-subpath of $S_{2}$. First assume that $y^{\prime} \neq x_{3}$. If $N\left(p_{j}\right) \cap\left\{x_{2}\right\}=\varnothing$ for every $1<j \leq i, V(R) \cup V\left(P^{p_{1} p_{i}}\right) \cup\{x, y\}$ induces a $3 P C\left(x x_{2} p_{1}, y\right)$. Otherwise let $T$ be a chordless $x_{2} y$-path contained in the graph induced by $V\left(P^{p_{2} p_{i}}\right) \cup\left\{x_{2}, y\right\}$. It follows that $V(T) \cup V(R) \cup\{x\}$ induces a $3 P C\left(x_{2}, y\right)$. So, $y^{\prime}=x_{3}$. If there exists a chordless $x_{2} y$-path $T$ contained in the graph induced by $V\left(P^{p_{2} p_{i}}\right) \cup\left\{x_{2}, y\right\}$, then $V\left(S_{2}\right) \cup V(T) \cup\{x\}$ induces a $3 P C\left(x x_{3} y, x_{2}\right)$. So $x_{2}$ has no neighbors in $P^{p_{2} p_{i}}$. Let $y^{\prime \prime}$ be the neighbor of $y$ in $H \backslash\left\{x_{2}\right\}$ that is closest to $x_{1}$. Then the $y^{\prime \prime} x_{1}$-subpath of $H \backslash\left\{x_{2}\right\}$, together with $V\left(P^{p_{1} p_{i}}\right) \cup\left\{x_{2}, y\right\}$, induces a hole $H^{\prime}$ and $\left(H^{\prime}, x\right)$ is a 3 -wheel, a contradiction.

Lemma 4.22 If $y$ is adjacent to $p_{1}$, then $N(y) \cap(V(H) \cup\{x\}) \subseteq\left\{x, x_{1}, x_{2}\right\}$.

Proof. Assume that $y$ is adjacent to $p_{1}$, but $N(y) \cap(V(H) \cup\{x\}) \nsubseteq\left\{x, x_{1}, x_{2}\right\}$.
(1) $y$ is adjacent to $x_{2}$.

Proof of (1). Assume otherwise and let $y^{\prime}$ be the neighbor of $y$ in $H \backslash\left\{x_{2}\right\}$ that is closest to $x_{1}$. If $y^{\prime} \neq x_{2}^{\prime}$, then the $y^{\prime} x_{1}$-subpath of $H \backslash\left\{x_{2}\right\}$, together with $\left\{x, x_{2}, y, p_{1}\right\}$, induces a 3 -wheel with center $x$. So, $y^{\prime}=x_{2}^{\prime}$. By Lemma 3.1, $(W, y)$ is an alternating wheel, and hence $y$ is adjacent to $p_{k}$. Let $H^{\prime}$ be the hole induced by $\left\{x_{2}, x_{2}^{\prime}, y, p_{1}\right\}$. Then $\left(H^{\prime}, p_{k}\right)$ is a 3 -wheel, a contradiction.
(2) $y$ is adjacent to $x$.

Proof of (2). Assume not. By (1), $x_{2} y \in E(G)$. The graph induced by $\left(V(H) \backslash\left\{x_{1}, x_{2}\right\}\right) \cup\{x, y\}$ contains a chordless $x y$-path $R, V(R) \cup\left\{p_{1}\right\}$ induces a hole $H^{\prime}$ and $\left(H^{\prime}, x_{2}\right)$ is a 3 -wheel, a contradiction.
(3) $y$ is adjacent to $x_{1}$.

Proof of (3). Assume not. By (1) and (2), $x y$ and $x_{2} y$ are both edges. Let $y^{\prime}$ be the neighbor of $y$ in $H \backslash\left\{x_{2}\right\}$ that is closest to $x_{1}$. First assume $y^{\prime} \neq x_{2}^{\prime}$, and let $R$ be the $y^{\prime} x_{1}$-subpath of $H \backslash\left\{x_{2}\right\}$. Then $V(R) \cup\left\{x_{2}, y\right\}$ induces a hole $H^{\prime}$ and $\left(H^{\prime}, x\right)$ is a 3 -wheel. So, $y^{\prime}=x_{2}^{\prime}$. Let $H^{\prime \prime}$ be the hole induced by $\left(V\left(S_{2}\right) \backslash\left\{x_{2}\right\}\right) \cup\{x, y\}$. Then $\left(H^{\prime \prime}, x_{2}\right)$ is a 3 -wheel, a contradiction.

By (1), (2) and (3), $\left\{x, x_{1}, x_{2}\right\} \subseteq N(y) \cap(V(H) \cup\{x\})$.
(4) $y$ is anticomplete to $\left\{x_{3}, \ldots, x_{n}\right\}$.

Proof of (4). $y$ is not adjacent to $x_{3}$ (resp. $x_{n}$ ), since otherwise $\left(H_{2}, y\right)$ (resp. $\left(H_{n}, y\right)$ ) is a 3 -wheel. Now assume that $y$ is adjacent to $x_{i}$ for some $3<i<n$. In particular, let $x_{i}$ be such a neighbor of $y$ in $H$ with lowest index. By Lemma 3.1, $(H, y)$ is an alternating wheel. If $i$ is even, then $\left(H_{i}, y\right)$ is a 3 -wheel. So, $i$ is odd.

Let $R$ be the $x_{2} x_{i}$-subpath of $H \backslash\left\{x_{1}\right\}$. If $y$ does not have a neighbor in $R \backslash\left\{x_{2}, x_{i}\right\}$, then $V(R) \cup\{x, y\}$ induces a 3 -wheel with center $x$. So, $y$ has a neighbor in $R \backslash\left\{x_{2}, \ldots, x_{i}\right\}$. Such a neighbor cannot belong to the interior of any long sector $S_{j}$ for $2<j<i-1$, since otherwise $y$ and $H_{j}$ contradict Lemma 3.1. Also, by Lemma 4.20, $y$ does not have a neighbor in the interior of both $S_{2}$ and $S_{i-1}$. W.l.o.g. assume that $y$ has a neighbor in the interior of $S_{i-1}$. Then $\left(H_{i-1}, y\right)$ is a wheel, and hence an alternating wheel, with appendix given by the $x_{2} x_{i-2}$-subpath of $R$. Since $\left|V\left(H_{i-1}\right)\right|<|V(H)|$, our choice of $(H, x)$ is contradicted.
(5) y has no neighbors in the interior of any long sector of $(H, x)$ that is not $S_{2}$.

Proof of (5). Assume otherwise. If $y$ has a neighbor in the interior of a long sector $S_{i}$ of $(H, x)$, for some $2<i<n$, then, by (4), $y$ and $H_{i}$ contradict Lemma 3.1. So $y$ has a neighbor in the interior of $S_{n}$ and $\left(H_{n}, y\right)$ is a wheel, and hence an alternating wheel, with rim shorter than $H$. By Lemma 4.20 and (4), $y$ is anticomplete to $V\left(S_{2}\right) \backslash\left\{x_{2}\right\}$, and hence $N(y) \cap V(H) \subseteq V\left(S_{n}\right) \cup\left\{x_{2}\right\}$. If $N(y) \cap V(P)=\left\{p_{1}\right\}$, then $\left(H_{n}, y\right)$ has an appendix induced by the $x_{2}^{\prime} x_{n-1}$-subpath of $H \backslash\left\{x_{2}\right\}$ together with $V(P)$, contradicting our choice of $(H, x)$. So, $y$ has a neighbor in $P \backslash\left\{p_{1}\right\}$ and let $p_{j}$ be such a neighbor with highest index. Let $y^{\prime}$ be the neighbor of $y$ in the interior of $S_{n}$ that is closest to $x_{n}$ on $S_{n}$. Then the $x_{2}^{\prime} y^{\prime}$-subpath of $H \backslash\left\{x_{2}\right\}$, together with $V\left(P^{p_{j} p_{k}}\right) \cup\{x, y\}$, induces a 1 -wheel with center $x$, a contradiction.

By (4) and (5), N(y) C ( $V(H) \subseteq\left(V\left(S_{2}\right) \backslash\left\{x_{3}\right\}\right) \cup\left\{x_{1}\right\}$ and, by our initial assumption, $y$ has a neighbor in the interior of $S_{2}$. It follows that $\left(H_{2}, y\right)$ is a wheel and hence an alternating wheel. Let $y^{\prime}$ be
the neighbor of $y$ in $S_{2}$ that is closest to $x_{3}$ and let $R$ be the $y^{\prime} x_{1}$-subpath of $H \backslash\left\{x_{2}\right\}$. Then the vertex set $V(R) \cup\{y\}$ induces a hole $H^{\prime}$ and $\left(H^{\prime}, x\right)$ is an alternating wheel with appendix induced by $\left(V(H) \backslash\left(V(R) \cup\left\{x_{2}\right\}\right)\right) \cup V(P)$. Since $\left|V\left(H^{\prime}\right)\right|<|V(H)|$, our choice of $(H, x)$ is contradicted.

Lemma $4.23 y$ is anticomplete to at least one of $N^{\prime}, M$.
Proof. Suppose that $y$ has a neighbor in both $N^{\prime}$ and $M$. It suffices to consider the following two cases.
Case 1: $y$ has a neighbor in $M$ and a neighbor in $N$.
(1) $(H, y)$ is an alternating wheel.

Proof of (1). It follows from our assumptions and Lemma 3.1.
(2) $y$ is not adjacent to $x$.

Proof of (2). Assume it is. By Lemmas 4.21 and $4.22, N(y) \cap V(P)=\varnothing$. Let $u$ (resp. $v$ ) be the neighbor of $y$ in $H \backslash\left\{x_{2}\right\}$ that is closest to $x_{2}^{\prime}$ (resp. $x_{1}$ ). By our assumptions, $u \in N$ and $v \in M \cup\left\{x_{1}\right\}$. Let $R$ be the $x_{2} u$-subpath of $H \backslash\left\{x_{1}\right\}$. If $y$ is not adjacent to $x_{2}$, then the $v x_{1}$-subpath of $H \backslash\left\{x_{2}\right\}$, together with $V(R) \cup\{y\}$, induces a hole $H^{\prime}$. Also, $\left(H^{\prime}, x\right)$ is a wheel, and hence an alternating wheel, with appendix $P$ and such that $\left|V\left(H^{\prime}\right)\right|<|V(H)|$, a contradiction. It follows that $x_{2} y$ is an edge. But then $V(P) \cup V(R) \cup\{x, y\}$ induces a 3 -wheel with center $x_{2}$, a contradiction.
(3) $(H, x)$ is a long alternating wheel.

Proof of (3). Assume not. So, $(H, x)$ is a line wheel. By (2), $x y$ is not an edge. Let $R$ be the chordless $x y$-path contained in the graph induced by $N^{\prime} \cup\{x, y\}$. If $y$ has a single neighbor in $S_{4}$, then this neighbor belongs to the interior of $S_{4}$, which contradicts (1). If $y$ has two neighbors in $S_{4}$, and these neighbors are adjacent, then $V\left(S_{4}\right) \cup V(R)$ induces a pyramid. It follows that $y$ has non-adjacent neighbors in $S_{4}$. But then the graph induced by $V\left(S_{4}\right) \cup V(R)$ contains a $3 P C(x, y)$, a contradiction.
By (2), $y$ is not adjacent to $x$. By (3), the graph induced by $M \cup\{x, y\}$ contains a chordless $x y$-path $R$. If $y$ has non-adjacent neighbors in $S_{2}$, then the graph induced by $V\left(S_{2}\right) \cup V(R)$ contains a $3 P C(x, y)$. So, by (1), $y$ has two neighbors in $S_{2}$ and these neighbors are adjacent. But then $V\left(S_{2}\right) \cup V(R)$ induces a pyramid, a contradiction.
Case 2: $y$ has a neighbor in $M$, a neighbor in $P$ and no neighbors in $N$.
(4) $y$ is not adjacent to $x$.

Proof of (4). Otherwise, by Lemma 4.21, yp $p_{1}$ is an edge, and so Lemma 4.22 is contradicted.
By (4), $x y$ is not an edge. Let $p_{i}$ be the neighbor of $y$ in $P$ with lowest index and let $R$ be the chordless $x y$-path induced by $V\left(P^{p_{1} p_{i}}\right) \cup\{x, y\}$.
(5) y has at least two neighbors in $H \backslash V\left(S_{2}\right)$.

Proof of (5). Suppose that $y^{\prime}$ is the unique neighbor of $y$ in $H \backslash V\left(S_{2}\right)$. Then $y^{\prime} \in M$ and hence, by Lemma 3.1, $N(y) \cap V(H)=\left\{y^{\prime}\right\}$. If $y^{\prime}$ belongs to the interior of a long sector $S_{i}$ of $(H, x)$, for some $4 \leq i \leq n$, then $V\left(S_{i}\right) \cup V(R)$ induces a $3 P C\left(x, y^{\prime}\right)$. So $y^{\prime}=x_{j}$ for some $4<j \leq n$. First assume that $j$ is even. Let $R^{\prime}$ be the chordless $x_{2} p_{i}$-path contained in the graph induced by $V\left(P^{p_{1} p_{i}}\right) \cup\left\{x_{2}\right\}$. Then the $x_{j} x_{2}$-subpath of $H \backslash\left\{x_{3}\right\}$, together with $V\left(R^{\prime}\right) \cup\{y\}$, induces a hole $H^{\prime}$ and $\left(H^{\prime}, x\right)$ is a 1-wheel. So, $j$ is
odd. Let $p_{r}$ be the neighbor of $y$ in $P$ with highest index. Then the $x_{2}^{\prime} x_{j}$-subpath of $H \backslash\left\{x_{2}\right\}$, together with $V\left(P^{p_{r} p_{k}}\right) \cup\{x, y\}$, induces a 1 -wheel with center $x$, a contradiction.
(6) y does not have non-adjacent neighbors in $H \backslash V\left(S_{2}\right)$.

Proof of (6). Otherwise the graph induced by the vertex set $\left(V(H) \backslash V\left(S_{2}\right)\right) \cup V(R)$ contains a $3 P C(x, y)$, a contradiction.

By (5) and (6), $y$ has two neighbors in $H \backslash V\left(S_{2}\right)$, say $y^{\prime}$ and $y^{\prime \prime}$, and $y^{\prime} y^{\prime \prime}$ is an edge. If they both belong to the same long sector $S_{i}$ of $(H, x)$, for some $4 \leq i \leq n$, then $V\left(S_{i}\right) \cup V(R)$ induces a $3 P C\left(y y^{\prime} y^{\prime \prime}, x\right)$. So, w.l.o.g. $y^{\prime}=x_{j}$ and $y^{\prime \prime}=x_{j+1}$ for some $4<j<n, j$ odd. By Lemma 3.1, $y$ is not adjacent to $x_{2}$. Let $R^{\prime}$ be the chordless $x_{2} p_{i}$-path contained in the graph induced by $V\left(P^{p_{1} p_{i}}\right) \cup\left\{x_{2}\right\}$. Then the $x_{j+1} x_{2}$-subpath of $H \backslash\left\{x_{3}\right\}$, together with $V\left(R^{\prime}\right) \cup\{y\}$, induces a hole $H^{\prime}$ and $\left(H^{\prime}, x\right)$ is a 1 -wheel, a contradiction.

Proof of Lemma 4.1 (under the assumption that Property 1 holds). Assume otherwise.
(1) y has no neighbors in $M$.

Proof of (1). Assume it does. By Lemma 4.23, $y$ has no neighbors in $N^{\prime}$. First suppose that $y$ has non-adjacent neighbors in $H \backslash N$. Let $y^{\prime}$ (resp. $y^{\prime \prime}$ ) be the one that is closest to $x_{2}$ (resp. $x_{3}$ ). Then the $y^{\prime} x_{2}$-subpath of $H \backslash N$, together with the $x_{3} y^{\prime \prime}$-subpath of $H \backslash N$ and $V\left(S_{2}\right) \cup\{y\}$, induces a hole $H^{\prime}$. By Lemma 3.1, $\left(H^{\prime}, x\right)$ is an alternating wheel with appendix $P$. By Lemma 3.1, $(H, y)$ is an alternating wheel and hence $\left|V\left(H^{\prime}\right)\right|<|V(H)|$, so that $\left(H^{\prime}, x\right)$ contradicts our choice of $(H, x)$. So, $y$ does not have non-adjacent neighbors in $H \backslash N$. It follows that $y$ is adjacent to $x$ and has a neighbor that belongs to the interior of a long sector $S_{i}$ of $(H, x)$, for some $4 \leq i \leq n$. But then $y$ and $H_{i}$ contradict Lemma 3.1.
(2) $y$ is not adjacent to $x_{1}$.

Proof of (2). Assume it is. By (1), $y$ has no neighbors in $M$. Suppose that $y$ has no neighbors in $V(H) \backslash\left\{x_{1}, x_{2}\right\}$. It follows that $y$ has a neighbor in $P$ and let $p_{i}$ be such a neighbor with highest index. Then $y$ is adjacent to $x$, since otherwise $\left(V(H) \backslash\left\{x_{2}\right\}\right) \cup V\left(P^{p_{i} p_{k}}\right) \cup\{x, y\}$ induces a 1 -wheel with center $x$. So, by Lemma 4.21, yp $p_{1}$ is an edge. Since $\left\{x, x_{1}, x_{2}, y, p_{1}\right\}$ cannot induce a 3 -wheel with center $x, y$ is adjacent to $x_{2}$. Therefore, $y$ is complete to $\left\{x, x_{1}, x_{2}, p_{1}\right\}$. If $N(y) \cap V(P)=\left\{p_{1}\right\}$, then $\left(V(H) \backslash\left\{x_{2}\right\}\right) \cup V(P) \cup\{x, y\}$ induces a 3 -wheel with center $x$. It follows that $\left\{p_{1}\right\} \subset N(y) \cap V(P)$. But then, by Lemma 3.1 applied to $W$ and $y, y$ is a special vertex of $G$, a contradiction.
So, $y$ has a neighbor in $H \backslash\left(M \cup\left\{x_{1}, x_{2}\right\}\right)$. Let $y^{\prime}$ be such a neighbor that is closest to $x_{4}$ and let $H^{\prime}$ be the hole induced by the $y^{\prime} x_{1}$-subpath of $H \backslash\left\{x_{2}\right\}$ together with $y$. By Lemma 3.1, $\left(H^{\prime}, x\right)$ is an alternating wheel, and hence $x y \in E(G)$ and $y^{\prime} \notin\left\{x_{3}, x_{4}\right\}$. By Lemma 3.1, $(H, y)$ is an alternating wheel, and so $x_{2} y$ is an edge. By Lemma 3.1, $(W, y)$ is an alternating wheel, and hence $y p_{1} \in E(G)$, contradicting Lemma 4.22.
(3) $y$ is not adjacent to $x_{4}$.

Proof of (3). Assume it is. By (1) and (2), $y$ has no neighbors in $M \cup\left\{x_{1}\right\}$. Suppose that $y$ has a neighbor in $P$. Then, by Lemmas 4.21 and $4.22, y$ is not adjacent to $x$. Let $R$ be a chordless $x_{2} y$-path contained in the graph induced by $V(P) \cup\left\{x_{2}, y\right\}$, and let $H^{\prime}$ be the hole induced by $\left(V(H) \backslash V\left(S_{2}\right)\right) \cup V(R)$. But then (since $x y$ is not an edge) $\left(H^{\prime}, x\right)$ is a 1 -wheel. Therefore $y$ has no neighbors in $P$. Since $N(y) \cap V(H)$ is not a clique, $y$ must have a neighbor in $S_{2} \backslash\left\{x_{3}\right\}$, and let $y^{\prime}$ be such a neighbor closest to $x_{2}$. Let $H^{\prime \prime}$ be the hole induced by $y$ together with the $x_{4} y^{\prime}$-subpath of $H \backslash\left\{x_{3}\right\}$. By Lemma 3.1, $\left(H^{\prime \prime}, x\right)$ is an
alternating wheel and hence $y$ is adjacent to $x$ and $y^{\prime} \neq x_{2}$. Also, by Lemma 3.1, $(H, y)$ is an alternating wheel, and so $\left|V\left(H^{\prime \prime}\right)\right|<|V(H)|$. Note that $P$ is an appendix of $\left(H^{\prime \prime}, x\right)$, and hence our choice of $(H, x)$ is contradicted.
(4) $y$ is not adjacent to $x_{2}$.

Proof of (4). Assume it is. By (1), (2) and (3), $y$ has no neighbors in $H \backslash V\left(S_{2}\right)$. First suppose that $y$ has no neighbors in $N$. Then $y$ is not adjacent to $x_{3}$, since otherwise $V\left(S_{2}\right) \cup\{x, y\}$ induces a theta or a 3 -wheel with center $x$. Now assume that $x y$ is an edge. By our assumptions, $y$ has a neighbor in $P \backslash\left\{p_{1}\right\}$. Then, by Lemma 4.21, $y$ is adjacent to $p_{1}$. Let $p_{i}$ be the neighbor of $y$ in $P$ with highest index, and note that $i>2$ since, by Lemma 3.1, $V(W) \cup\{y\}$ must induce an alternating wheel. It follows that the chordless path induced by $V\left(P^{p_{i} p_{k}}\right) \cup\{y\}$ is an appendix of $(H, x)$ that is shorter than $P$, a contradiction.
So, $y$ is not adjacent to $x$ and has a neighbor in $P$. Let $p_{j}$ (resp. $p_{r}$ ) be the neighbor of $y$ in $P$ with lowest (resp. highest) index. First suppose that $j \neq r$ and $p_{j} p_{r}$ is not an edge. By Lemma 3.1, $(W, y)$ is an alternating wheel, and so $r>j+3$. Therefore the chordless path induced by $V\left(P^{p_{1} p_{j}}\right) \cup V\left(P^{p_{r} p_{k}}\right) \cup\{y\}$ is an appendix of $(H, x)$ that is shorter than $P$, a contradiction. Now assume that $p_{j} p_{r}$ is an edge. Since $N(y) \cap\left(V(P) \cup\left\{x_{2}\right\}\right)$ is not a clique of size $3, x_{2}$ is not adjacent to at least one of $p_{j}, p_{r}$ and hence the graph induced by $V(P) \cup\left\{x_{2}, y\right\}$ contains a 1 -wheel or a 3 -wheel with center $y$. It follows that $j=r$ and $x_{2} p_{j}$ is not an edge. But then the graph induced by $V(P) \cup\left\{x_{2}, y\right\}$ contains a theta, a contradiction.
So, $y$ has a neighbor in $N$, and let $y^{\prime}$ be the one that is closest to $x_{3}$ on $S_{2}$. First assume $y^{\prime}=x_{2}^{\prime}$. Then $y$ is anticomplete to $\left\{x, x_{3}\right\}$, since otherwise $V\left(S_{2}\right) \cup\{x, y\}$ induces a 1 -wheel or a 3 -wheel with center $y$. So, by our assumptions, $y$ has a neighbor in $P \backslash\left\{p_{k}\right\}$ and let $p_{\ell}$ be the one with lowest index. By Lemma 3.1, $(W, y)$ is an alternating wheel, and so $\ell<k-1$. By Lemma $4.22, \ell>1$, and hence the chordless path induced by $V\left(P^{p_{1} p_{\ell}}\right) \cup\{y\}$ is an appendix of $(H, x)$ that is shorter than $P$, a contradiction.
So, $y^{\prime} \neq x_{2}^{\prime}$ and $V\left(S_{2}\right) \cup\{x, y\}$ induces an alternating wheel with center $y$. If $y$ is adjacent to $x$, then the $y^{\prime} x_{2}$-subpath of $H \backslash\left\{x_{2}^{\prime}\right\}$, together with $\{x, y\}$, induces a 3 -wheel with center $x$. So, $y$ is adjacent to $x_{2}^{\prime}$ and not adjacent to $x$. Also, $(W, y)$ is an alternating wheel and hence $y$ is adjacent to $p_{k}$. Let $p_{s}$ be the neighbor of $y$ in $P$ with lowest index. By Lemma 4.22, $s>1$. In particular, $s>2$ and $x_{2} p_{s}$ is an edge, since otherwise the $y^{\prime} x_{3}$-subpath of $S_{2}$, together with $V\left(P^{p_{1} p_{s}}\right) \cup\left\{x, x_{2}, y\right\}$, induces a 1 -wheel or a 3 -wheel with center $x_{2}$. Let $H^{\prime}$ be the hole induced by the $y^{\prime} x_{2}$-subpath of $H \backslash\left\{x_{2}^{\prime}\right\}$ together with $y$. Then $\left(H^{\prime}, x\right)$ is an alternating wheel with appendix $P^{p_{1} p_{s}}$ and such that $\left|V\left(H^{\prime}\right)\right|<|V(H)|$, which contradicts our choice of $(H, x)$.
(5) y has no neighbors in $V\left(S_{2}\right) \backslash\left\{x_{2}\right\}$.

Proof of (5). Assume it does and let $y^{\prime}$ be such a neighbor that is closest to $x_{3}$. If $y^{\prime}=x_{2}^{\prime}$, then $y$ is not adjacent to $x$ (else $V\left(S_{2}\right) \cup\{x, y\}$ induces a theta) and so, since $N(y) \cap(V(H) \cup V(P) \cup\{x\})$ is not a clique, $y$ has a neighbor in $P \backslash\left\{p_{k}\right\}$. This implies that the graph induced by $V\left(S_{2}\right) \cup\left(V(P) \backslash\left\{p_{k}\right\}\right) \cup\{x, y\}$ contains a $3 P C\left(x x_{2} p_{1}, x_{2}^{\prime}\right)$. So, $y^{\prime} \neq x_{2}^{\prime}$. By (1), (2), (3) and (4), $y$ is anticomplete to $M \cup\left\{x_{1}, x_{2}, x_{4}\right\}$. Let $R$ be the $y^{\prime} x_{2}$-subpath of $H \backslash\left\{x_{2}^{\prime}\right\}$. First suppose that $N(y) \cap V(P) \neq \varnothing$. Let $p_{i}$ (resp. $p_{j}$ ) be the neighbor of $y$ in $P$ with lowest (resp. highest) index. By Lemma 4.22, $i>1$. Then, by Lemma 4.21, $x y$ is not an edge. If $i \neq j$ and $p_{i} p_{j}$ is not an edge, then the graph induced by $V(R) \cup V\left(P^{p_{1} p_{i}}\right) \cup V\left(P^{p_{j} p_{k}}\right) \cup\{y\}$ contains a $3 P C\left(y, x_{2}\right)$. Now assume that $p_{i} p_{j}$ is an edge. If $x_{2}$ is not adjacent to both $p_{i}$ and $p_{j}$, then the graph induced by $V(R) \cup V(P) \cup\{y\}$ contains a $3 P C\left(p_{i} p_{j} y, x_{2}\right)$. So, $x_{2}$ is adjacent to both $p_{i}$ and $p_{j}$. Since ( $W, x_{2}$ ) is an alternating wheel, $i>2$ and $p_{i-1}$ is not adjacent to $x_{2}$. It follows that the $y^{\prime} x_{3}$-subpath of $S_{2}$, together with $V\left(P^{p_{1} p_{i}}\right) \cup\left\{x, x_{2}, y\right\}$, induces a 1 -wheel with center $x_{2}$, a contradiction.

Therefore, $i=j$. By Lemma 3.1, $(W, y)$ is an alternating wheel. So, $N(y) \cap V(P)=\left\{p_{k}\right\}, y$ is adjacent to $x_{2}^{\prime}$ and $x_{2}^{\prime} y^{\prime}$ is not an edge. Then the $y^{\prime} x_{3}$-subpath of $S_{2}$, together with $\left\{x, x_{2}, x_{2}^{\prime}, y, p_{k}\right\}$, induces a 3 -wheel with center $p_{k}$, a contradiction.
It follows that $y$ has no neighbors in $P$. Let $y^{\prime \prime}$ be the neighbor of $y$ in $V\left(S_{2}\right) \backslash\left\{x_{2}\right\}$ that is closest to $x_{2}^{\prime}$. If $y$ is adjacent to $x$ then, by Lemma 3.1, $(W, y)$ is an alternating wheel and hence $y^{\prime}=x_{3}, y^{\prime} \neq y^{\prime \prime}$ and $y^{\prime} y^{\prime \prime}$ is not an edge. So, the $x_{2}^{\prime} y^{\prime \prime}$-subpath of $H \backslash\left\{x_{2}\right\}$, together with $V(R) \cup\{x, y\}$, induces a 3 -wheel with center $x$. Therefore, $y$ is not adjacent to $x$. Since $N(y) \cap(V(H) \cup V(P) \cup\{x\})$ is not a clique, $y^{\prime} \neq y^{\prime \prime}, y^{\prime} y^{\prime \prime}$ is not an edge and hence, by Lemma 3.1, $(W, y)$ is an alternating wheel. It follows that the $x_{2}^{\prime} y^{\prime \prime}$-subpath of $H \backslash\left\{x_{2}\right\}$, together with $V(R) \cup\{y\}$, induces a hole $H^{\prime}$ that is shorter than $H$. Also, $\left(H^{\prime}, x\right)$ is an alternating wheel with appendix $P$, a contradiction.

By $(1),(2),(3),(4)$ and $(5), N(y) \cap(V(H) \cup V(P) \cup\{x\}) \subseteq V(P) \cup\{x\}$ and, since $N(y) \cap(V(H) \cup V(P) \cup\{x\})$ is not a clique, by Lemma 3.1, $(W, y)$ is an alternating wheel. If $y$ is not adjacent to $x$, then the graph induced by $V(P) \cup\{y\}$ contains a chordless $p_{1} p_{k}$-path that contains $y$ and is an appendix of $(H, x)$ that is shorter than $P$, a contradiction. So, $y$ is adjacent to $x$ and hence $\left\{p_{1}\right\} \subset N(y) \cap V(P)$. Let $p_{i}$ be the neighbor of $y$ in $P$ with highest index. Then the graph induced by $V\left(P^{p_{i} p_{k}}\right) \cup\left\{x, x_{2}, y, p_{1}\right\}$ contains a 3 -wheel with center $p_{1}$, a contradiction.

## Property 2 holds.

We now assume that $G$ satisfies Property 2. The wheel $(H, x)$ and other associated notation are as in the beginning of Section 4.

Proof of Lemma 4.1 (under the assumption that Property 2 holds). Let $y \in V(G) \backslash(V(H) \cup\{x\})$ and assume that $N(y) \cap(V(H) \cup\{x\})$ is not a clique. We consider the following two cases.

Case 1: $y$ is adjacent to $x$.
(1) For every long sector $S_{i}$ of $(H, x)$, either $N(y) \cap V\left(S_{i}\right) \subseteq\left\{x_{j}\right\}$ for $i \leq j \leq i+1$ or $\left(H_{i}, y\right)$ is a line wheel.

Proof of (1). Note that $y$ cannot be adjacent to both $x_{i}$ and $x_{i+1}$, since otherwise $\left(H_{i}, y\right)$ is a 3 -wheel. If $y$ has a neighbor in the interior of $S_{i}$ then, by Lemma 3.1, $\left(H_{i}, y\right)$ is an alternating wheel. In particular, by our choice of $(H, x),\left(H_{i}, y\right)$ is a line wheel and hence (1) holds.
(2) $y$ is complete to a short sector of $(H, x)$.

Proof of (2). Assume otherwise. W.l.o.g. $y$ has a neighbor in a long sector $S_{i}$ of $(H, x)$. Therefore, by (1), $y$ has a neighbor in $\left\{x_{i}, x_{i+1}\right\}$. So w.l.o.g. assume that $y$ is adjacent to $x_{i}$. Let $y^{\prime}$ be the neighbor of $y$ in $H \backslash\left\{x_{i}\right\}$ that is closest to $x_{i-1}$ (it exists since $N(y) \cap(V(H) \cup\{x\})$ is not a clique). By (1), $y^{\prime} \neq x_{i}^{\prime}$. But then the $y^{\prime} x_{i}$-subpath of $H$ that contains $x_{i-1}$, together with $\{x, y\}$, induces a 3 -wheel with center $x$, a contradiction.

By (2), w.l.o.g. we may assume that $y$ is complete to $S_{1}$. Also, by our assumptions, $y$ has a neighbor in $H \backslash\left\{x_{1}, x_{2}\right\}$.
(3) $y$ has a neighbor in $\left\{x_{3}, \ldots, x_{n}\right\}$.

Proof of (3). Assume otherwise. Then $y$ has a neighbor in the interior of a long sector of $(H, x)$, say $S_{i}$. Note that $i=2$ or $i=n$, since otherwise (1) is contradicted. W.l.o.g. $i=2$ and let $y^{\prime}$ be the neighbor of $y$ in the interior of $S_{2}$ that is closest to $x_{3}$ on $S_{2}$. By $(1), y^{\prime} \neq x_{2}^{\prime}$. By Lemma 4.20, $y$ has no neighbors in the interior of $S_{n}$. But then the $y^{\prime} x_{1}$-subpath of $H \backslash\left\{x_{2}\right\}$, together with $\{x, y\}$, induces a long alternating wheel with center $x$ and rim shorter than $H$, a contradiction.
(4) $y$ is anticomplete to $\left\{x_{3}, x_{4}, x_{n-1}, x_{n}\right\}$.

Proof of (4). Assume not and w.l.o.g. suppose that $y$ has a neighbor in $\left\{x_{3}, x_{4}\right\}$. By (1), $x_{3} y$ is not an edge. But then the graph induced by $V\left(S_{2}\right) \cup\left\{x, x_{4}, y\right\}$ contains a 3 -wheel with center $x$, a contradiction.

By (3) and (4), $y$ is adjacent to $x_{i}$ for some $4<i<n-1$. W.l.o.g. assume that $y$ has no neighbors in $\left\{x_{3}, x_{4}, \ldots, x_{i-1}\right\}$.
(5) $i$ is odd, and $x_{2}$ and $x_{i}$ are not consecutive neighbors of $y$ in $H$.

Proof of (5). Let $R$ be the $x_{2} x_{i}$-subpath of $H \backslash\left\{x_{1}\right\}$ and let $y^{\prime}$ be the neighbor of $y$ in $R \backslash\left\{x_{i}\right\}$ that is closest to $x_{i}$ on $R$. Let $R^{\prime}$ be the $y^{\prime} x_{i}$-subpath of $R$. If $i$ is even or $y^{\prime}=x_{2}$, then $V\left(R^{\prime}\right) \cup\{x, y\}$ induces a 3 -wheel with center $x$. Therefore, (5) holds.

By (5), $y$ has a neighbor in the interior of a long sector $S_{j}$ of $(H, x)$, for some $1<j<i$. By ( 1 ), $j=2$ or $j=i-1$. So, w.l.o.g. assume $j=2$ and, by (1), let $y^{\prime}$ and $y^{\prime \prime}$ be the adjacent neighbors of $y$ in the interior of $S_{2}$, where $y^{\prime}$ is closer to $x_{2}$ on $S_{2}$. By Lemma 4.20, $y^{\prime \prime}$ and $x_{i}$ are consecutive neighbors of $y$ in $H$. Also, since $\left(H_{2}, y\right)$ is a line wheel, $y^{\prime}$ is not adjacent to $x_{2}$. Let $H^{\prime}$ be the hole induced by the $y^{\prime \prime} x_{i}$-subpath of $H \backslash\left\{x_{2}\right\}$ together with $y$. Then $\left(H^{\prime}, x\right)$ is an alternating wheel with appendix given by the $x_{2} y^{\prime}$-subpath of $S_{2}$, a contradiction.

Case 2: $y$ is not adjacent to $x$.
(6) $(H, y)$ is an alternating wheel.

Proof of (6). Since $N(y) \cap V(H)$ is not a clique, $y$ has at least two non-adjacent neighbors in $H$ and so, by Lemma 3.1, (6) holds.
W.l.o.g. assume that $y$ has a neighbor is $S_{2}$.
(7) $N(y) \cap V(H) \subseteq V\left(S_{2}\right) \cup\left\{x_{1}, x_{4}\right\}$.

Proof of (7). Assume not. Then the graph induced by $\left(V(H) \backslash\left(V\left(S_{2}\right) \cup\left\{x_{1}, x_{4}\right\}\right)\right) \cup\{x, y\}$ contains a chordless $x y$-path $R$. If $y$ has non-adjacent neighbors in $S_{2}$, then the graph induced by $V\left(S_{2}\right) \cup V(R)$ contains a $3 P C(x, y)$. If $y$ has exactly two neighbors in $S_{2}$ then, by Lemma 3.1 applied to $y$ and $H_{2}$, they are adjacent and hence $V\left(S_{2}\right) \cup V(R)$ induces a pyramid. Therefore $y$ has a unique neighbor $y^{\prime}$ in $S_{2}$. If $y^{\prime} \notin\left\{x_{2}, x_{3}\right\}$ then $V\left(S_{2}\right) \cup V(R)$ induces a $3 P C\left(x, y^{\prime}\right)$. So w.l.o.g. $y^{\prime}=x_{2}$. Let $y^{\prime \prime}$ be the neighbor of $y$ in $H \backslash V\left(S_{2}\right)$ that is closest to $x_{4}$. Since $y^{\prime \prime} \neq x_{1}$, the $x_{2} y^{\prime \prime}$-subpath of $H$ that contains $x_{3}$, together with $\{x, y\}$, induces a 1-wheel with center $x$, a contradiction.
Let $y^{\prime}$ (resp. $y^{\prime \prime}$ ) be the neighbor of $y$ in the path induced by $V\left(S_{2}\right) \cup\left\{x_{1}, x_{4}\right\}$ that is closest to $x_{1}$ (resp. $x_{4}$ ). By (6) and (7), the $y^{\prime} y^{\prime \prime}$-subpath of $H$ that contains $x_{5}$, together with $y$, induces a hole $H^{\prime}$ that is shorter than $H$. By Lemma 3.1, $\left(H^{\prime}, x\right)$ is an alternating wheel, thus contradicting our choice of $(H, x)$.

## 5 Proof of Theorem 1.13

Proof of Theorem 1.13. Our proof is by induction on $|V(G)|$. By Theorem $1.8, G$ is the line graph of a triangle-free graph or it admits a clique cutset or a small 2-amalgam. Let us consider these three cases.

Case 1: $G$ is the line graph of a triangle-free graph.
By Vizing's theorem, $\chi(G) \leq \omega(G)+1 \leq 4$, which completes the proof.
Case 2: $G$ admits a clique cutset.
Let $K$ be a clique cutset of $G$, let $C_{1}, \ldots, C_{k}, k \geq 2$, be the connected components of $G \backslash K$, and, for every $1 \leq i \leq k$, let $G_{i}=G\left[V\left(C_{i}\right) \cup K\right]$. By induction, for every $1 \leq i \leq k, G_{i}$ is 4-colorable. For $1 \leq i \leq k$, let $c_{i}$ be a 4-coloring of $G_{i}$. Since $K$ is a clique, vertices of $K$ must have different colors in all of these colorings. So, we can permute the colors of $c_{i}$ 's so that they all agree on the colors of the vertices of $K$, and by putting together such colorings we get a 4-coloring of $G$.

Case 3: $G$ admits a small 2-amalgam.
Let $\left(\{x\}, V_{1}, V_{2}\right)$ be a small 2-amalgam of $G$, and let $W_{1}=\left\{x_{1}\right\}, W_{2}=\left\{x_{2}\right\}, Z_{1}=\left\{x_{4}\right\}$ and $Z_{2}=\left\{x_{3}\right\}$. Let $G_{1}=G\left[V_{1} \cup\left\{x, x_{2}, x_{3}\right\}\right]$ and $G_{2}=G\left[V_{2} \cup\left\{x, x_{1}, x_{4}\right\}\right]$. Since $G$ is $K_{4}$-free, $\omega(G)=\omega\left(G_{1}\right)=\omega\left(G_{2}\right)=3$. Let $c_{1}$ (resp. $c_{2}$ ) be a 4-coloring of $G_{1}$ (resp. $G_{2}$ ). W.l.o.g. assume that $c_{1}$ and $c_{2}$ agree on $\left\{x, x_{1}, x_{2}\right\}$. If they also agree on $\left\{x_{3}, x_{4}\right\}$, then we are done. So, consider the case where they do not agree. W.l.o.g. suppose $c_{1}(x)=c_{2}(x)=1, c_{1}\left(x_{1}\right)=c_{2}\left(x_{1}\right)=2$ and $c_{1}\left(x_{2}\right)=c_{2}\left(x_{2}\right)=3$.
If $c_{1}\left(x_{4}\right) \neq c_{2}\left(x_{3}\right)$, then we can obtain a 4 -coloring of $G$ by coloring every vertex from $V\left(G_{1}\right) \backslash\left\{x_{3}\right\}$ with the same color as in the coloring $c_{1}$, and by coloring every vertex from $V\left(G_{2}\right) \backslash\left\{x_{4}\right\}$ with the same color as in the coloring $c_{2}$.

So, assume that $c_{1}\left(x_{4}\right)=c_{2}\left(x_{3}\right)$. First suppose that $c_{1}\left(x_{4}\right) \in\{2,3\}$. Then w.l.o.g. we may assume that $c_{1}\left(x_{4}\right)=2$. To obtain a 4-coloring $c$ of $G$ we first color every vertex from $V\left(G_{1}\right) \backslash\left\{x_{3}\right\}$ with the same color as in the coloring $c_{1}$. Then, for a vertex $v \in V_{2}$ we define $c(v)$ in the following way: $c(v)=c_{2}(v)$ if $c_{2}(v) \in\{1,3\}, c(v)=2$ if $c_{2}(v)=4$, and $c(v)=4$ if $c_{2}(v)=2$.

Finally, let $c_{1}\left(x_{4}\right)=c_{2}\left(x_{3}\right)=4$. To obtain a 4-coloring $c$ of $G$ we first color every vertex from $V\left(G_{1}\right) \backslash\left\{x_{3}\right\}$ with the same color as in the coloring $c_{1}$. Then, for a vertex $v \in V_{2}$ we define $c(v)$ in the following way: $c(v)=c_{2}(v)$ if $c_{2}(v) \in\{1,3\}, c(v)=2$ if $c_{2}(v)=4$, and $c(v)=4$ if $c_{2}(v)=2$.
