Abstract

The concept of adaptation is becoming part of mainstream public discourse on climate change. Yet the diversity, complexity and novelty of the adaptation concept itself leads to interpretive flexibility, differing public understanding of (and engagement with) adaptation strategies, and hence differentiated policy responses. The boundary work of communicative practices and public understanding of the adaptation concept therefore require empirical analysis in different cases and contexts. This study employs Q-methodology, a combined quantitative-qualitative social research method, to reveal the typologies of perspectives that emerge around the adaptation concept amongst a diverse group of citizen-stakeholders in the United Kingdom. Four such typologies are identified under the labels: 1) Top-down climate action, 2) Collective action on climate change, 3) Optimistic, values-focused adaptation, and 4) Adaptation skepticism. The division between these perspectives reveals a perceived “responsibility gap” between the governmental-institutional and/or individual-community levels. Across the emergent discourses we find a consensual call for a multi-sector, multi-scalar and multi-stakeholder-led approach that posits adaptation as a contemporary, intra-generational problem, with a strong emphasis upon managing extreme weather events; and not an abstract future problem. By attending to these public discourses in climate policy, this is a potential means to lessen such a responsibility gap.

Climate adaptation, Q-methodology, climate change communication, responsibility

Introduction - adapting to climate change

Adaptation is a process by which human actors as individuals, communities, regions, national or trans-national entities act in order to cope with the consequences of climate change. Even with rapid greenhouse gas emission stabilisation/reduction globally, the long reaction times within climate systems mean that global temperatures will still increase, requiring remedial actions to ameliorate emergent negative environmental and socio-economic impacts. This necessitates combined technical and societal responses to reduce systemic vulnerability to climate variability effects.

Despite potential benefits such as longer growing seasons in cooler countries (e.g. Linderholm 2006) or more efficient shipping routes through an ice-free Arctic (Smith and Stephenson 2013), the negative impacts of climate change are significant and far reaching. These include (but are not limited to) increased incidence/intensity of extreme weather events (Stott et al. 2016), biodiversity redistribution and loss (Pacifci et al. 2015; Pecl et al. 2017), extinction risks (Urban 2015), disruption to ecosystem services (Geneletti and Zardo 2016; Lavorel et al. 2015), heat stress (Deryng et al. 2014; Lindberg et al. 2016; Voskamp and Van de Ven 2015), drought (Trenberth et al. 2014), sea-level rise and coastal flooding (Carson et al. 2016; Clark et al. 2016), fluvial and pluvial flooding (Arnell and Gosling 2016; Kaspersen et al. 2017; Kundzewicz et al. 2014), ocean acidification (Boyd et al. 2015; Riebesell and Gattuso 2014) and growing resource restrictions such as loss of potable water supply (Döll et al. 2015; Khan et al. 2015), crop failure (Challinor et al. 2014), associated negative socio-economic effects from supply disruption within infrastructure networks (Chappin and van der Lei 2014) and negative impacts upon public health (Watts et al. 2015).

Climate change affects multiple aspects of human economic and social activity, but the impacts are (or will be) highly differentiated by sector (agriculture, infrastructure, marine management, flood defense etc.) and will affect different countries/regions/communities/individuals in multiple ways based upon their vulnerability and relative adaptive capacity. It is important for decision-makers to question the extent to which adaptation reduces the risks of climate change, what policies are needed, and how can they best be developed and applied (Burton et al. 2002). This requires knowledge of how adaptation choices are made under conditions of resource constraint and uncertainty, and how existing policies can be amended or 'climate proofed' (Urwin and Jordan 2008); whilst avoiding the risks of maladaptation - whereby actions that or initiatives that foster short-term gains but insidiously affect systems' long-term vulnerability and/or adaptive capacity to climate change over the longer term (Barnett and O'Neill 2010). This picture is further complicated by the fact that adaptation pathways are mediated by the relative socio-political, cultural and economic status of different actors involved (Brooks et al. 2005). They are context-specific - there is no single adaptation response that can cover all outcomes in all cases. It is therefore necessary for adaptation strategies to be sensitive to the underlying political and cultural roots of such actions (Pelling 2010). Adger (2003) argues, therefore, that adaptation is best understood as a dynamic social process: one that is commonly understood to require a localized, bottom-up, place-based and co-produced approach in order to be successful (Lo and Jim 2015; Meadow et al. 2015; Rayner 2010; Van Aalst et al. 2008).

Adaptation as a matter of public perception and environmental communication

The influence of public perceptions in shaping policy preferences and individual adaptation outcomes is an important aspect of climate change politics. However, the question of how to take into account heterogeneous public and stakeholder values, perceptions and concerns in a local, bottom-up and co-produced manner remains fraught with communicative barriers. Whether at the level of policy-making or individual action, the question of *how* to adapt is subject to framing effects, in which choices are influenced by the way in which the problem is conceptualised and presented to decision-makers (Chong and Druckman 2007; Frisch 1993; Lakoff 2010; McEvoy et al. 2010; Nisbet 2009; O'Brien et al. 2007). Perceptions of everything from changes to local weather patterns to the validity of long-term climate forecasts are subject to cultural biases and political ideology (Goebbert et al. 2012; Hulme 2009; McNeeley and Lazrus 2014). In practice, adaptation research and policy is, as Adger et al. (2013) note, primarily focused upon the material aspects (such as technological solutions, or quantifiable impacts to ecosystems or livelihoods), yet the so-called 'softer' social and cultural aspects have been less thoroughly researched and integrated into policy.

One specific social dimension of adaptation concerns environmental communication and broader public engagement with the concept itself. Adaptation has received relatively little coverage in print and televised media, as discourses surrounding the mitigation of high impact/low probability climate impacts have remained dominant (Anderson 2009; Boykoff 2007). Although within climate change policy and planning something of adaptation-mitigation dichotomy has emerged (Biesbroek et al. 2015; Moser 2012), the two concepts are principally scientific constructs and so non-expert citizens may not perceive them as mutually exclusive. For example both terms can be conflated or confused (Moser 2014) or else mutually framed within public discourse within a wider sustainability umbrella (Chilvers et al., 2014). There is therefore, as Moser (2014) argues, a need to communicate specific adaptation risks and realities to multiple stakeholder audiences in a more effective way.

Though there is a pressing need for better adaptation communication, climate communicators encounter numerous barriers to effective engagement (Lorenzoni et al. 2007; Moser and Ekstrom 2010). Such barriers include (a relative lack of) stakeholder awareness, problems of scientific uncertainty around the estimates of future greenhouse gas emissions and in projections of future climate impacts, the relative psychological/spatial/temporal distance through which many in developed countries perceive climate change (Spence et al. 2012); alongside communication resource constraints and a lack of underlying political commitment (Clar et al. 2013; Eisenack et al. 2014). Commonly cited solutions include awareness raising activities, and closing knowledge gaps through decision-support frameworks (Clar et al. 2013). Yet as Storbjörk (2007) notes, there is persistent confusion over what the term adaptation encompasses and what it hopes to achieve; and though low public awareness about adaptation is associated with a lack of action, simply disseminating knowledge about climate change impacts, vulnerabilities and adaptive capacity is unlikely to remove existing barriers to adaptation and lead to positive action (Archie et al. 2012; Moser and Ekstrom 2010). The conceptual complexity of adaptation produces heterogeneous mental models of its nature and impacts amongst diverse stakeholder groups (Otto-Banaszak et al. 2011); and because adaptation incorporates a huge array of actions carried out across a wide variety of settings by a number of different actors under different institutional and scalar governance constraints, multi-stakeholder engagement with citizens, public bodies and interest groups, businesses and government organizations involves a wide differentiation of responsibilities within each of these interested parties (Adger et al. 2005).

We can conclude from this problem of adaptation communication that “success” is subject to a negotiation amongst competing stakeholder interests, which each have differing conceptions of the core concept. This means that adaptation is essentially a type of *boundary work* (Gieryn 1999), in the sense that the conceptual plasticity of adaptation involves socially constructed demarcation of adaptation concepts and practices and the negotiation of these at multiple geographic and governance scales. It is necessary, therefore, to present climate change adaptation in a way that is meaningful to non-experts and avoid engagement within a narrow bounded rationality that focuses solely upon scientific issues (particularly as framing climate change in adaptation-terms may be more engaging for individuals who show low concern for climate change overall, see: Howell et al. 2016). In order to mobilise knowledge about adaptation in a way that is credible, salient and politically legitimate, what is required is a more citizen-centered examination of adaptation perceptions and issues (Leith 2011) to better explore multiple definitions and meanings. It is this *boundary work*, exploring the conceptual plasticity of adaptation and how it is discursively demarcated, that is under consideration in this empirical study. We suggest that given the relative novelty of the climate adaptation concept in broader public debate amongst citizen-stakeholders (and hence the potential for publics’ differentiated and complex interpretations of it), and given the lack of media coverage and policy debate on the topic, further qualitative exploration of subjective representations of the concept is necessary in order to better understand typologies of heterogeneous citizen-stakeholder perspectives on the issue (and hence inform adaptation communication practices). In this empirical social scientific study of adaptation amongst citizen-stakeholders in the United Kingdom, we apply a mixed-method qualitative-quantitative approach termed “Q-methodology” to explore this conceptual diversity and we report upon the relevance of these findings for climate adaptation communicative practice. Q-method has shown considerable value in exploring subjective perspectives on a range of environmental management issues ranging from energy (Cotton and Devine-Wright 2011; Cuppen et al. 2010; Venables et al. 2009), forestry (Steelman and Maguire 1999), to agriculture and conservation (Bumbudsanpharoke et al. 2009). The method has also been

applied in climate change (principally mitigation) perceptions and engagement research in recent years (Burke et al. 2018; Lo 2016; O'Neill and Nicholson-Cole 2009; O'Neill et al. 2013), and this study aims to complement these findings through a specific emphasis on *adaptation* discourse within this broader field.

Understanding public perspectives on climate adaptation – a role for Q-methodology

Q-methodology (hereafter referred to as *Q-method*), is a specialist social research method, designed by Stephenson (1953) as a means to analyze subjective opinion (Cross 2005). Q-method quantitatively maps subjective attitudes and opinions, rendering them open to statistical analysis. It enables researchers to identify a number of *discourses* (sometimes referred to as *idealized accounts*) around a topic. Unlike social survey methods which impose specific categories against which attitudes are measured, Q-method examines subjectivity from the standpoint of the person experiencing it (Brown 1996). It is in this way that we use the method for the study of the boundary work of the climate adaptation concept - it combines quantitative and qualitative techniques in order to reveal the relevant *types* of perspective in a population, rather than the *prevalence* of such types. It is therefore valuable in explaining how and why people think they way that they do about climate adaptation, rather than counting how many people think one way or another (see for example Tielen et al. 2008).

Though statistical in nature, Q-method is consistent with post-positivist social scientific analysis (Durning 1999); particularly in relation to the analysis of discourse (see Dryzek 1990 for examination of this point). As Cotton (2015) suggests, Q-method has value in its capacity to mediate between the micro-discursive realm of individual statements of belief and social practices, and the macro-discursive realm of broader social and environmental discourses. Using Q-method allows us to link individual stakeholder perspectives to broader debate within civil society on the management of climate adaptation. Thus Q-method is chosen, as Dasgupta and Vira (2005) suggest, because it is highly suited to researching adaptation as a social phenomenon around which there is conceptual novelty, debate, conflict and contestation.

Q-Methodology in practice

In this Q-method study we follow a five-stage research plan.

1. Defining a concourse
2. Selecting the statements for Q-sorting
3. Selecting a participant sample (P-sample)
4. Q-sorting the statements
5. Analysing and interpreting the results.

1. Defining a concourse

A *concourse* refers to “the flow of communicability surrounding any topic” (Brown 1993) – the concourse encapsulates the range of positions taken on the climate change adaptation concept. It is ultimately from this concourse of ideas that Q-method collates and correlates individual responses and extracts idealized forms of discourse latent in the data provided by the individuals in the study (Brown 1996; McKeown and Thomas 1988). The concourse is a

collected set of statements from which we draw a representative sample (Watts and Stenner 2012). This collected set was gleaned by using Boolean search operators within well-known databases (Google, Google Scholar, Scopus, Web of Knowledge and Nexis). In sequence: “climate change adaptation”, then searches with “climate change adaptation” AND operator for “strategy OR strategies”, “media”, “social”, “perception OR perceptions”, “policy OR policies”, “responsibility OR responsibilities”, “individual OR individuals”. These searches produced a series of secondary sources to form a *ready-made* Q-sample, drawing statements (primarily) from academic, NGO, policy document, weblog, and activist written sources (we collected 210 statements in total for the complete concourse).

An inductive content analysis of the findings was used to code the retrieved documents and generate statement categories through which to sample statements used in the Q-sort process. The content analysis allowed us to alternate between specific categories and emergent relationships within the corpus of materials and also to quantify and categorize the text responses that form the raw material for the processes of selecting statements for subsequent Q-sorting.

2. *Selecting the statements for Q-sorting*

As Brown (1993) suggests, the selection process for those statements to be included remains “*more art than science*”. The statements collected were selected to encapsulate the various standpoints and cover as many sub-issues within the topic as possible so that the participants can truly express their views. It must be noted, however, that is only when the participants are sorting the statements that the statements have *meaning* (Watts and Stenner 2012). However, it behooves Q-researchers to provide structure to the selection to ensure that obvious biases within the corpus of materials can be eliminated or ameliorated. This is done by forcing the researcher to select a wide variety of statements in order to make the Q-set broadly representative.

In practice, we selected a subset of statements from the concourse for presentation to the participants (called the Q-sample, or sometimes Q-set). Structuring the Q-sample introduces some overt bias in statement selection, and as it is ultimately the researcher that makes the selection of statements deemed relevant then different researchers would make different selections from the same concourse (van Exel and de Graaf 2005). Wording may also differ, so we piloted the statement set with student participants (not included in the final dataset) specifically on wording. It must be noted that ambiguity of the statements is not in itself a problem. This is because participants give their own meaning to the statements based on where they are sorted and they will interpret statements in their own way (Coogan and Herrington 2011). We expect, therefore, as Thomas and Baas (1992) argue, that different statements, constructed in different ways from the same concourse will still produce similar conclusions. This is because the Q-method operation is subjective and represents an individual’s point of view; there is no external criterion for evaluating an individual’s response to a particular statement, thus, each individual’s set of rank-ordered statements is deemed a valid expression of his or her opinion (Brown 1993).

To select statements, we followed a procedure similar to that of McLaughlin and Cutts ((in press)). First, we developed the concourse of statements. Second, we thematically coded the statements into five overarching themes, based on a reasonable assessment and interpretation of each statement. Third, duplicate and confusing statements were eliminated from the initial

concourse. Fourth, another statement elimination process was conducted from feedback collected from a mock pilot study with students. Fifth, statements were randomly eliminated from each theme to maintain equal statement counts within each theme for a Q-set total of 34 statements. Sixth, the selected Q-set was independently checked by an academic not involved in this study. Finally, the set was discussed between authors to ensure that they were “unambiguous, non-contentious, and comprehensive” (Spurgeon et al. 2012) to ensure balance, breadth, and applicability to the issue of climate change adaptation. The statements were then numbered and printed on cards in preparation of the Q-sort. The thematic analysis categories and some example statements are listed below:

Theme: Potential impacts and outcomes

- Statement 13: The implementation of climate change adaptation strategies will alter my lifestyle significantly.
- Statement 25: Adapting to climate change will be detrimental to economic growth and opportunity.

Theme: Technologies and strategies

- Statement 8: Adaptation to climate change should be focused on traditional, hard techniques such as structural adjustments e.g. sea walls to combat rising sea levels.
- Statement 9: Adaptation strategies and mitigation strategies must complement one another.

Theme: Responsibilities (political and moral)

- Statement 5: Climate change adaptation strategies will disproportionately affect the world’s poorest people.
- Statement 34: Climate change adaptation must be a collaborative effort and must involve a range of stakeholders (e.g. general public, business sector, local government, national government).

Theme: Knowledge, perception and awareness

- Statement 7: I am concerned about the melting of the polar icecaps”
- Statement 19: Climate change has dropped off the agenda.”

Theme: Limitations and barriers

- Statement 6: When barriers, such as technological requirements and financial limitations, are overcome then society will be able to successfully adapt to a changing climate.

3. *Selecting a participant sample (P-sample)*

In our study, as in other Q-method case studies, a comparatively small number of participants is desirable (when compared to R-method surveys). Brown (1980) argues that “all that is required are enough subjects to establish the existence of a factor for purposes of comparing one factor to another”. The underlying premise of the method is that within a community, there are fewer ways of thinking of a given topic than there are people (Neff 2014). Consequently, the number of participants in the P-set makes is typically smaller than the number of statements in the Q-sample. As in a range of similar environmental social science studies using Q-methodology (Cuppen et al. 2010; Steelman and Maguire 1999; Wolsink

2010) our participant sampling (P-sample) was intended to represent diversity of knowledge, experiences (and hence differing perspectives) amongst citizen-stakeholders: in essence those that are likely to have a distinct viewpoint on the problem in hand, which will in turn, give meaning to their responses (Robbins and Kreuger 2001). However, as Watts and Stenner (2005) suggest, it is better under such circumstances to avoid a priori assumptions based upon preconceived demographic categorization. Q-method allows individuals to self-categorize on the basis of the item configurations they produce, so opportunistic or purposive sampling techniques are recommended over random sampling in the manner of an R-survey (Brouwer 1999).

During the period May-July 2015, 30 returned Q-sorts from a geographically and professionally diverse group of citizen-stakeholders constitute the primary data for this study. The age range for the purposively sampled P-set was 18-68 (Male: 17, Female 13). Some Q-sorts were conducted face-to-face and others by post (though this is not expected to yield a difference in result, see Tubergen and Olins 1979). A variety of professional backgrounds including both 'lay' (non-specialist) perspectives, as well as those with specific stakeholder interests related to climate change adaptation outcomes - including environmental, local government, urban and transport planning, public health and agriculture knowledge/experience were represented. Details are shown in the second column of Table 1.

4. *Q-sorting*

The participants "Q-sorted" the statements according to the condition of instruction (van Exel and de Graaf 2005) i.e. to sort the cards from *most like my opinion* (+4) to *least like my opinion* (-4). 0 is neutral. As is common in Q-method studies, respondents were instructed to adhere to a pre-determined (in this case forced quasi-normal) distribution as shown in Figure 1. It is customary to conduct short post-sort questionnaire to allowing participants to reflect and further define their position on the statements within the Q-sort. We altered this protocol by instructing participants to instead annotate the back of each of the statement cards, and to write down their reflections upon each Q-sort statement on the other side – allowing personal sorter reflections to be easily traceable back to each of the Q-set items. Examples of these short statements are included as qualitative data in the discussion section to further contextualize the Q-sorts, paying specific attention to the comments related to Q-statements that define factors, and to the responses of those Q-sorters whose positions strongly correlate with the associated factor (as indicated in Table 1). Where participants' reflections are included, their written responses are labelled P#.

5. *Analysis and interpretation of results*

Complete Q-sorts were analyzed using PQMethod software. A correlation matrix of all Q-sorts was subject to factor analysis (in this case principal components analysis, PCA). A four-factor solution was retained, explaining 62% of total variance. The four-factor solution was chosen as each factor was statistically significant with an Eigenvalue >1.00, with at least two Q-sorts loading on each factor (factors 5+ did not meet these two criteria). The four factors were then rotated using Varimax, which seeks to ensure that each Q-sort had a high factor loading to only one of the study factors, and that the factors are positioned in such a way that the final solution maximizes the amount of study variance explained. Participant loadings on factors are shown in Table 1. Participants (each individual Q-sort) are numbered 1-30. Loadings on factors are highlighted in bold to show defining sorts for that factor, i.e. the

exemplars that reveal the shared item pattern or configuration that is characteristic of that factor (Watts and Stenner 2012).

We interpret the factors as a series of summarizing accounts: each of which aims to explain the viewpoint being expressed by each factor and hence produce an ideal or aggregated perspective (which we refer to as a *discourses*). Each discourse is an *interpretation* of positions expressed within the Q-sorting process, constructed by careful reference to the positioning and overall configuration of the items in the relevant best-estimate factor arrays (Watts and Stenner 2012). In interpreting the discourses, we followed Stevenson's (2015) and Cuppen et al's (2010) method: we examine statements that have the highest and lowest scores for each factor (statements ranked at +4 and -4 for each factor) to set the context of the discourse, combined with discussion of the distinguishing statements (i.e. statements that were ranked significantly differently between a given factor and all other factors, and the statements that were not ranked differently by any factors, see: Webler et al. 2009).

Table 2 shows the list of statements and factor Q-sort values for each. In the narrative description statements numbers are indicated alongside the Q-sort value score in the composite factor array; e.g. (s10, -4*) indicated statement number 10 loaded at -4 (least like my perspective). The distinguishing statements for each factor marked ^ are significant at P<.05; statements marked * are significant at P<.01.

Each factor is given a moniker or label to summarize the salient features of the account:

- Discourse 1: *Top-down climate action* (D1)
- Discourse 2: *Collective action on climate change* (D2)
- Discourse 3: *Optimistic, values-focused adaptation* (D3)
- Discourse 4: *Adaptation skepticism* (D4)

Discourse 1 –Top-down climate action (D1)

The context to this discourse is that climate change is deemed by proponents to be an urgent, deeply significant and personal issue that cannot be ignored (and that they would not want to ignore it) (s27, -4). Specific threats/negative climate change impacts such as extreme weather events (flood, drought, storms) are believed to be a significant risk (s22, +4); and the reporting of these threats from climate change in the media is not exaggerated or amplified (s12, -4), implying a true representation of the risks involved. In terms of the response to these threats, it is noteworthy that this account does not prioritize mitigation measures over adaptation (s33, -2*), as P10 qualifies:

“I believe that this (mitigation prioritization) is true in a perfect world but we have possibly already passed a tipping point, therefore we have to plan to adapt just as much as we should to mitigate (in relation to S33).”

This implies that proponents of this discourse advocate a holistic approach to the climate change issue, noting that adaptation is an essential component (s26, +3*) of climate change strategy. However, when it comes to extreme climate change impacts (defined as those that related to 4°C or greater warming scenarios) adaptation is construed as contributing to or detracting from the urgency of the issue overall (s10, -3*).

With regards to the management responsibilities it is significant that although across all discourses there is support for multi-stakeholder collaboration across multiple scales of

public and private sector and civil society interest., This viewpoint indicates a preference for Government-level responsibility in adaptation and mitigation planning decisions (s3, +2*) specifically as they relate to Government incentivisation to remove financial barriers to adaptation planning and encourage technological development strategies (s31, +2[^].) as opposed to a focus upon the individual (s30, -2) and individual values (s16, 0*). As P26 states:

I'm not sure how I prioritise my values. Certainly I think about my family first (in relation to statement 16)

In summary, this discourse represents a perspective that is sure of the risks posed by anthropogenic climate change, and the urgency for personal and political action in relation to this perceived threat. However, this personal concern with the climate change issue (in its broadest sense), translates into a call for more urgent and decisive action on adaptation planning, policy and decision-making specifically at the international (s28, +3) and national scale (s3, +2) rather than upon individual responsibility for personal adaptation and the prioritisation of (pro-environmental/pro-adaptation-related) personal values, in part as it appears, because the idea of personal value prioritization did not resonate with proponents of this discourse. As P15 states:

Climate change is too big for individuals, and collective global action is needed at the highest level (in relation to s3).

This discourse could therefore be interpreted as a call for greater top-down intervention from government and transnational organizations in response to climate change, whilst also emphasizing the importance and urgency of adaptation within this.

Discourse 2: Collective action on climate change (D2)

Like discourse 1 (D1), discourse 2 (D2) is contextualized by an overarching concern for the immediacy and scale of long-term anthropogenic climate change impacts: such as the increased probability and intensity of extreme weather events, flood and drought (s22, +4); that adaptation is both an issue that is urgent in terms of international political cooperation and collaboration in policy making (s28, -2*), and one that may or may not be exaggerated by media reporting of the issue (s12, 0*). As P4 states:

If anything the issue has been under-exaggerated (sic) (in relation to s12).

This urgency at the international level is mirrored in other scales of climate governance. There is key emphasis upon action as a collaborative effort across different sections of civil society including government and private sector interests (s34, +4), of which individual responsibility organized at the community level has a part to play (s30, +2*). As P15 states:

It's the "one person jumps nothing happens, but if one hundred people jump it's enough to make a change in noise and vibration" thing (in relation to s30).

Also in common with D1 is a concern with Government playing a leading role in both adaptation-related decision-making (s3, +3) and in the removal of financial and technological barriers to adaptation (s31, +3), with a sense that it is these barriers that must be overcome in order for adaptation to be successful (s6, +1[^]). However, there is a marked difference in the perception of adaptation as a Government response to the climate change problem. D2 is

distinguished as something of a pro-mitigation viewpoint disputing the necessity of adaptation as a component of broader climate change strategy (s26, -4), preferring that mitigation is prioritized over adaptation (s33, +2[^]). As P24 summarizes:

Mitigation will be significantly cheaper and easier in the long run than adaptation (in relation to s26).

However, it was strongly disputed that adaptation should remain the lowest priority on the government agenda (s2, -3). On the whole, climate change mitigation and adaptation are both viewed as having a role, despite a lean towards mitigation. This is partly explained by a pessimism over collective/societal capacity to adapt in the face of severe climatic variability under high emissions scenarios (s10, -4).

To summarize, this discourse represents a position that is, as with D1, concerned with urgency and potential impact of climate change, yet is skeptical of encouraging action on adaptation. In part, this is explained by a position that adaptation is not possible in the face of high cost climate-related impacts such as extreme weather events, and so mitigation should be prioritized. Proponents of this perspective show a greater concern with multi-level governance at different scales of action – stressing urgency in international and national political action on climate change as a collective action problem, alongside responsibilities for stakeholders across public and private interests, and individual and community-level actions on mitigation. This suggests that proponents of this discourse favor action on mitigation prioritized over adaptation and that this in turn is linked to a preference for multi-scalar collective action solutions.

Discourse 3 – Optimistic values-focused adaptation (D3)

Like D1 and D2, this perspective displays a similar emphasis upon the role of Government in prioritizing climate change – asserting that economic development and other welfare issues should not be prioritized over long-term climate change policy and planning (s2, -4*), whilst remaining relatively neutral on the prioritization of mitigation-versus-adaptation in the policy process (s9, 0[^]). There is only a slight expressed preference for mitigation (s33, +1[^]), in contrast to other discourses (D2 and D4). Proponents of this discourse do not perceive that involvement in adaptation planning presents an opportunity cost for society that would worsen the economy (s13, -3[^]).

What differentiates this perspective is that the emphasis is clearly upon the individual and their role in adaptation responses as an expression of personal moral and socio-political values. Like D2, there is a (in this case very strong) support for focusing upon adaptation at the level of the individual acting within a community-level adaptation setting (s30, +4*). Specific to this discourse unlike any of the others is an optimism over civil society capacity to adapt is expressed in the context of individuals prioritizing personal climate adaptation values (s16, +3[^]), which themselves will have influence upon the strategies chosen in adaptation (s18, +4*). As P29 states:

Individual values need to be about compassion and respect for others less fortunate than ourselves, if we had that then we would all act on climate change (in relation to s16).

To summarize, this discourse represents an optimistic position on the adaptive capacity of the UK in the face of climate change impacts. Though it recognizes the importance of

government action at nation and international levels, proponents of this discourse prioritize individual action, specifically of climate change related values, including individual responsibility and empathy for vulnerable people, and hence seek to overcome the potential political and financial barriers to adaptation that may emerge.

Discourse 4 – Adaptation skepticism (D4)

The context to this discourse is, like D1, D2 and D3, that climate change remains on the political agenda (s19, -4) and that on a personal level, proponents of this discourse wish to engage with the issue, rather than ignore it (s27, -4). There is a sense of being concerned with the risks that it presents to UK society. As seen in discourse 2, there is strong expression of a pro-mitigation preference (s33, +4*), as P6 states:

Surely we can't keep adapting to change - there has to be a point where we can't adapt (in relation to s3).

However, unlike the other discourses, there is skepticism - that the effects of climate change have been exaggerated by media reporting on the issue (s12, +2*). This is potentially indicative of concern of media over-stretch: whereby media exaggeration of dread environmental risks prompts acts as a barrier to collective action on climate change (see for example Weingart et al. 2000).

This discourse presents further skepticism of the relative value of adaptation in relation to both its perceived benefits and drawbacks. Proponents of this discourse assert that any adaptation measures put into place will have little impact upon our relative adaptive capacity to climate change (s14, +2*), or upon individual lifestyles and social practices (s15, -3*) in the face of such threats, linking with the reduced sense of non-governmental actors' power demonstrated in this discourse (s3, -3). As P9 states:

Mitigation of risks are a higher priority and will have a greater impact on climate change (in relation to s14).

The position presented in this discourse stands in contrast to the IPCC's assertion that sustainable development, community vulnerability and climate change are linked; this discourse reveals expressed skepticism about the disproportionate impacts of climate change upon the world's poorest people (s5, -2*), or that assessing the vulnerability of such communities is important in adapting to climate change (s17, -2*). It is notably the only discourse that takes this stance on those two statements. This can be interpreted as a *climate-change-affects-everyone* stance, particularly in light of the strong assertion that climate change adaptation (and in the context of the other statements in this discourse, mitigation) must be a collaborative, multi-stakeholder effort (s34, +4).

Discussion

As in Lo's (2016) study of climate change discourses in Hong Kong, we assert that Q-method allows us insight into the different groupings of stakeholder perspectives on climate adaptation and their socio-political underpinnings – in essence it reveals the ways in which heterogeneous public actors socially construct and demarcate the adaptation concept in discourse. Unlike a traditional social survey, we seek not to measure traits that are 'out there' in the world, but rather to determine segments of subjectivities that a person, or groups of people, have toward a particular context or phenomenon (Hutson et al. 2010). We make no

claims about the relative prevalence of adaptation perspectives nor its geographic/demographic distribution; and as Martin (2008) asserts, there is no fundamental reason to assume that representation in terms of demographic variables would translate into representation in terms of perspectives (see also Cuppen et al. 2010).

Our use of principal components analysis of 30 Q-sorts and subsequent qualitative interpretation of the factors reveal the *typologies* of perspectives emergent in the debate. One feature of this analysis is to uncover the statements that do not distinguish between factors (Table 3) and those that do (Table 4). The former are indicative of discursive *consensus* and hence of adaptation strategies/policies/ideas that will likely encounter support (or at least little resistance) from citizen-stakeholder actors. The latter are indicative of disagreement amongst competing stakeholder perspectives and are therefore worthy of further research and constructive multi-stakeholder dialogue in the development of adaptation strategy.

Certain Q-statements separate certain discourse from others. Notable in this regard is s3. We note that *Top-down Climate Action* D1 and *Collective Action on Mitigation* D2 indicate a preference for government-led action with regards to climate change strategies. In the UK context, adaptation has been reframed in recent years as ‘weather resilience’, ‘community protection’ or ‘livelihood protection’. This raises some concerns amongst academic and climate advocacy actors about the ability and appetite of UK local governments to address climate adaptation directly (Porter et al. 2015). In this context, we postulate that there are different preferences around adaptation *responsibilities*, specifically. Notably the division is between proponents of top-down intervention on adaptation (proponents of D1 and D2), versus those that favor individual responsibility as a reflection of personal values (D3) and those that are simply more skeptical about adaptation as a moral hazard in relation to mitigation (D4).

The differentiation in the framing of adaptation *responsibility* is pertinent to ongoing debates surrounding *common but differentiated responsibility* in climate governance. The concept was initially applied to state interactions internationally in negotiating heterogeneous domestic GHG reduction commitments based upon differential development status and relative capacity to act (Rajamani 2000). Climate change responsibilities are commonly framed as: those that cause the problem are morally responsible for solving it, i.e. the Polluter Pays Principle. Yet descriptions of common but differentiated responsibility in international and domestic law do not provide a complete account of who should bear the burdens of global climate change (Caney 2005). Scholarship on adaptation responsibilities has commonly focused upon defining responsibility for impacts, fair burden sharing, and the distribution of adaptation assistance either to vulnerable countries (Paavola and Adger 2006), or to specific social groups (including, for example, tribes Whyte 2013). Yet this literature is less clear about the differentiation of *responsibilities* for adaptation measures at multiple scales and policy/legal domains. The most commonly cited solution is to build common responsibility amongst different stakeholder groups by binding them through collective action (Adger 2003), and/or through active involvement in multi-stakeholder adaptation planning measures (Storbjörk 2007). It is notable in our findings, therefore, that the inclusion of multiple stakeholders in adaptation planning was agreed to be important from all perspectives (s34). However, the key differences between these discourses are held in regard to the responsibility and adaptive capacity of individuals. The importance of the individual’s role at the foundation of successful adaptation strategies was demonstrated within D2 and D3 (s30). Optimism about the perceived capabilities of the individual in D3 and the role of collective action is also evidenced D2. *Optimistic Values-Focused Adaptation* D3 is the only

discourse that supports the idea of an individual responsibility to rethink personal values to align with adaptation priorities (s16), suggesting onus upon the individual, rather than the state, to act on adaptation. It is only D4, The *Adaptation Skepticism* view suggests that individuals should be less concerned with their own values (s16) nor should adaptive actions seek to begin at the individual or community level (s30) as there the individual level holds no power to address climate change.

Given the discursive differences in the perceived role for top-down governmental and inter-governmental authorities versus the individual, there is a potential conflict that may emerge, which we argue represents a *responsibility gap* if both institutional authorities and individual citizens effectively ‘offload’ their responsibilities to the other party, so to speak. As there is no consensus on the level and types of responsibilities that different actors at different scales hold, greater clarity is needed within policy about which stakeholders (from public institutions to citizen-stakeholders) have which responsibilities at specific geographic, institutional and temporal scales, particularly given the overall preference for a collaborative, multi-stakeholder approach to the issue (s34). We see a key area of climate adaptation discourse and further action for both environmental policy research and climate policy-authorities, to examine the differentiated sense of responsibility between citizen-stakeholders and public authorities, and within that a differentiated role for *values* in addressing the social limits to adaptation (see for example Adger et al. 2009).

As noted above, the solution to a responsibility gap in adaptation is likely a *collaborative* one, taking place across multiple levels from government to the individual, given the consensus across discourses on this type of approach. D3 showed the weakest agreement with a collaborative multi-stakeholder approach, though it is more broadly ‘bottom-up’ and citizen-led in its outlook towards adaptation, which is congruent with a collaborative model of citizen engagement and collective action. When combined with the agreement amongst the other three discourses for ‘top down’ public authority-led climate change (adaptation) responsibility, this reinforces the status of adaptation based on incremental and participatory actions rather than more centrally-controlled transformative approaches (see for example Wise et al. 2014), in the sense that a multi-stakeholder, collective focus on adaptive responsibility posits climate adaptation as a societal risk: requiring collective, community and place-based, rather than individual, action.

Of further concern is that the dichotomy of mitigation-adaptation is repeated in our findings here. D1 for example expressed that climate change mitigation should not be prioritized over adaptation (s33) in contrast to the other three discourses. A preference for mitigation amongst D2, D3, and D4 is potentially grounded in a principled argument for responsibility to reduce climate change risks, rather than minimize their effects. This is most clearly shown in D2 (s26). Yet preference within the mitigation-adaptation dichotomy is in part related to the relative optimism shown towards the success of adaptation strategies, *specifically* D1 & D3 strongly oppose the idea that successful adaptation is merely a theoretical notion (s14) and even *Adaptation Scepticism* D4 articulated that there is some role for adaptation within the climate change policy response (though less than D1 and D3).

The areas of contention within the viewpoints do not define the climate change adaptation discourse alone, i.e. those statements that were not distinguished by any one factor. These statements are indicative of agreement on the value attributed to them across the four viewpoints and can be (tentatively) described as consensus viewpoints. Despite differences of

opinion over the causes and consequences of climate change across the discourses, all demonstrated a preference to remain *aware* of climate change risks rather than to ignore them (s27) with D1 and D4 demonstrating this most strongly. This ‘awareness’ centered upon the risks of climate change, specifically extreme weather events (s22) which had strong agreement across the discourses, and that a collaborative multi-stakeholder approach is needed (s34). This is tentatively indicative of a strong pro-climate change action-position as consensual across the accounts, in the sense that there is no strong skepticism about the scientific basis of anthropogenic climate change expressed in the accounts here. There was also agreement that adaptation alone may not be sufficient to cope with climate change (s1), and that traditional ‘hard’ engineered strategies should not be the only type of climate adaptation response taken (s8). Collectively we can interpret this consensus representing a collective concern for long-term climate risks, that this is imagined as a socio-technical problem (rather than solely technical problem), one that requires a collaborative solution, and that this solution must involve adaptation and mitigation components (to varying degrees across the competing perspectives). There was agreement that prioritizing adaptation within policy would be unlikely to worsen any other issues that the United Kingdom was facing (s13), in essence that it was not perceived as an additional undue financial burden to society. This is potentially explained by a belief that planning for adaptation to climate change is not a novel phenomenon (s23) or one that has dropped off the agenda (S19). This has significance because previous studies of climate change perceptions reveal climate change to be perceived as a remote, future problem (see for example Wolf and Moser 2011), and yet the incidence of extreme weather events and the perceptual relationship to adaptation makes this appear as a more immediate problem.

We can infer that there is general support for measures to combat extreme weather-related impacts, but that these are generally perceived as contemporary issues for policy and public expenditure rather than abstract future problems (potentially evidenced by people’s exposure to images of recent high profile flooding-related events, see Capstick et al. 2015). In short, our data can be interpreted as showing that adaptation planning is perceived as compatible with meeting the needs of current citizens (an *intra*-generational) rather than a future (*inter*-generational) climate change problem, though the prevalence of this discursive framing through demographically representative survey work would be a fruitful line of future research.

Concluding remarks

This study has demonstrated the boundary work of the adaptation concept - exploring the range of viewpoints across citizen-stakeholders’ multiple interpretations and relationships between these interpretations. This is because Q-method has the capacity to explore the contextual discursive attempts to reconcile competing understandings and definitions of the problem of climate change adaptation (see for example Shackley and Wynne 1996). The issue of boundary work in climate change research has predominantly focused upon boundaries between policy and expert worlds – through the attempts by such actors to define practices around climate science-to environmental policy in contrast to one another through demarcation, and other attempts to find productive cooperation across boundaries (in contrast to a model of science policy interactions that essentialises climate science as something that can be ‘transferred’ to policy, planning and public opinion) (Hoppe 2010). Yet given that adaptation is understood as a ‘bottom-up’, place-based and public-engagement focused practice (Rayner 2010; Schreurs 2008), it is important to understand the ways in which public

actors engage in boundary work – how they discursively demarcate the adaptation concept and its proposed solutions. Our research shows that across heterogeneous stakeholder perspectives (including those of lay public actors) there are key areas of agreement on the value of adaptation within broader climate policy, of a multi-stakeholder and ‘soft’ social adaptation process, that complements, but does not replace climate mitigation at the core of environmental policy. However, although climate change is consensually posited as an issue which participants collectively wanted to ‘keep on the agenda’ (a finding likely welcomed by advocates of climate change action), it remains the only admission of responsibility demonstrated across all four viewpoints. The discourses were split on whether this issue of adaptation was the responsibility of government to address, or whether it required a more holistic approach to achieve the most successful outcome. We can conclude, therefore, that this *responsibility gap* within adaptation discourse between citizen-stakeholders and public authorities, is an issue requiring urgent research and response from UK policy-makers and climate change communicators in addressing the social limits to climate adaptation.

N.B. Numbers in **bold** represent a defining sort for that factor

Table 2 Q-sort statements and factor arrays

Statement	Factor			
	1	2	3	4
1 In the long term, adaptation strategies alone may not be sufficient to cope with all the projected impacts of climate change.	+2	+3	+2	+3
2 There are always other costs that the government <i>should</i> prioritise over adapting to climate change e.g. the economy, welfare concerns.	-1*	-3*	-4^	0*
3 The only power to make real decisions about climate change adaptation is achieved through policy at a national government level.	+2*	+3*	-2	-3
4 Engagement with the public on potential climate change adaptation is the responsibility of local agencies (e.g. local gov. and local industries/businesses) to engage with the public.	-2	-1*	0	0
5 Climate change adaptation strategies will disproportionately affect the world's poorest people.	+1	0	+2	-1*
6 When barriers, such as technological requirements and financial limitations, are overcome then society will be able to successfully adapt to a changing climate.	-1	+1*	-1	-2
7 I am concerned about the melting of the polar ice caps.	+2	+1	+3	0
8 Adaptation to climate change should be focused on traditional, hard techniques such as structural adjustments e.g. sea walls to combat rising sea levels.	-2	-3	-2	-2
9 Adaptation strategies and mitigation strategies must complement one another.	+3	+2	0^	+3
10 An average global temperature increase of four degrees by the end of the century is something that humanity can adapt to.	-3*	-4*	+1^	0^
11 'Climate change adaptation' is a loosely defined term.	0	-1	-1	+1
12 I think that the potential effects of climate change have been exaggerated by the media and other outlets.	-4	0^	-4	+2^
13 Other problems that society is currently facing could be worsened if government policy prioritises climate change adaptation e.g. economic recovery may be hindered.	-1	-1	-3*	-1
14 Adapting to the effects of change is a good idea in theory but it will never have a real world impact on climate as an issue.	-3	0	-3	+2^
15 The implementation of climate change adaptation strategies will alter my lifestyle significantly.	0	-1	0	-3^
16 As humans continue to develop, individuals and groups need to prioritise their own values to meet the requirements for adapting to climate change.	0*	-2	+3^	-3
17 A successful strategy of adaptation is only achievable when there is full understanding of who is or could become vulnerable.	0	+1	0	-2^
18 The values of individuals will have a significant influence on the success of potential climate change adaptation strategies.	+1	0	+4^	+1
19 Climate change has dropped off the agenda	-3	-3	-1^	-4*
20 Strategies to adapt to climate change will be most effective in the local, community setting.	-1	+2	+3	-1
21 I am unsure what strategies fall under the term of 'climate change adaptation'.	0	0	-2	-1
22 As climate changes, the probability of extreme weather events will increase (e.g. extreme flooding, droughts and storms).	+4	+4	+2	+2
23 Planning for adaptation to climate change is not a new thing.	+1	+1	0	0
24 In order for climate change adaptation strategies to be wholly worthwhile they must actively seek to achieve additional benefits as well as adapting to climate change (e.g. job creation).	+1	-1	-3	+1
25 Adapting to climate change will be detrimental to economic growth and opportunity.	-1	-2	-2	0
26 Successful adaptation is an absolute necessity in addressing the problem of climate change.	+3^	-4^	+1	+1

27	I would prefer to ignore climate change as an issue.	-4	-2	-1	-4
28	There is a lack of urgency at an international level with regards to addressing climate change as an issue.	+3	-2 [^]	+1 [^]	+3
29	The United Kingdom has the capabilities to adapt to the effects of climate change.	0	0	+2	+1
30	Any successful attempts to address climate change must begin with individuals (at a community level).	-2	+2 [^]	+4 [^]	-2
31	It is the role of the government to remove any barriers to climate change adaptation strategies (such as financial limits and technological requirements).	+2*	+3*	-1	-1
32	We need to clearly prioritise the type of adaptation strategies that are being implemented e.g. flood management vs. heat stress.	+1	+1	0	+2
33	The focus should always remain on climate change mitigation strategies rather than adaptation strategies.	-2 [^]	+2*	+1*	+4 [^]
34	Climate change adaptation must be a collaborative effort and must involve a range of stakeholders (e.g. general public, business sector, local government, national government).	+4	+4	+1 [^]	+4

Table 3 Statements that do not distinguish between factors

Statement	Factor			
	1	2	3	4
34. Climate change adaptation must be a collaborative effort and must involve a range of stakeholders (e.g. general public, business sector, local government, national government).	+4	+4	+1	+4
22. As climate changes, the probability of extreme weather events will increase (e.g. extreme flooding, droughts and storms).	+4	+4	+2	+2
1. In the long term, adaptation strategies alone may not be sufficient to cope with all the projected impacts of climate change.	+2	+3	+2	+3
23. Planning for adaptation to climate change is not a new thing.	+1	+1	0	0
19. Climate change has dropped off the agenda	-3	-3	-1	-4
27. I would prefer to ignore climate change as an issue.	-4	-2	-1	-4
8. Adaptation to climate change should be focused on traditional, hard techniques such as structural adjustments e.g. sea walls to combat rising sea levels.	-2	-3	-2	-2
13. Other problems that society is currently facing could be worsened if government policy prioritises climate change adaptation e.g. economic recovery may be hindered.	-1	-1	-3	-1

N.B. All statements non-significant at $>P=.05$

Table 4 Statements that distinguish between factors

Statement	Factor			
	1	2	3	4
3. The only power to make real decisions about climate change adaptation is achieved through policy at a national government level.	+2	+3	-2	-3
14. Adapting to the effects of change is a good idea in theory but it will never have a real-world impact on climate change as an issue.	-3	0	-3	+2
16. As humans continue to develop, individuals and groups need to prioritise their own values to meet the requirements for adapting to climate change.	0	-2	+3	-3
26. Successful adaptation is an absolute necessity in addressing the problem of climate change.	+3	-4	+1	+1
30. Any successful attempts to address climate change must begin with individuals (at a community level).	-2	+2	+4	-2
33. The focus should always remain on climate change mitigation strategies rather than adaptation strategies.	-2	+2	+1	+4
