13 **Main Conclusion:** Transgenic western wheatgrass degrades the explosive RDX and detoxifies TNT

14 **ABSTRACT**

15 Contamination, from the explosives, hexahydro-1, 3, 5-trinitro-1, 3, 5-triazine (RDX) and 2, 4, 6-
16 trinitrotoluene (TNT), especially on live-fire training ranges, threatens environmental and human health.
17 Phytoremediation is an approach that could be used to clean-up explosive pollution, but it is hindered by
18 inherently low *in planta* RDX degradation rates, and the high phytotoxicity of TNT. The bacterial genes,
19 *xplA*, and *xplB*, confer the ability to degrade RDX in plants, and a bacterial nitroreductase gene *nfsI*,
20 enhances the capacity of plants to withstand and detoxify TNT. While previous studies have used model
21 plant species to demonstrate the efficacy of this technology, trials using plant species able to thrive in the
22 challenging environments found on military training ranges are now urgently needed. Perennial western
23 wheatgrass (*Pascopyrum smithii*) is a United States native species that is broadly distributed across North
24 America, well-suited for phytoremediation, and used by the US military to re-vegetate military ranges.
25 Here we present the first report of the genetic transformation of western wheatgrass. Plant lines
26 transformed with *xplA*, *xplB* and *nfsI* removed significantly more RDX from hydroponic solutions and
27 retained much lower, or undetectable, levels of RDX in their leaf tissues when compared to wild-type
28 plants. Furthermore, these plants were also more resistant to TNT toxicity, and detoxified more TNT than
29 wild-type plants. This is the first study to engineer a field-applicable grass species capable of both RDX
30 degradation and TNT detoxification. Together, these findings present a promising biotechnological
31 approach to sustainably contain, and remove, RDX and TNT from training range soil and prevent
32 groundwater contamination.

33 **Keywords:** phytoremediation; RDX; TNT; western wheatgrass; transformation, monocot promoters;
34 stacked genes.

35 INTRODUCTION

36 The explosives hexahydro-1, 3, 5-trinitro-1, 3, 5-triazine (RDX) and 2,4,6-trinitrotoluene (TNT) are used
37 extensively by the US military. These compounds are damaging to the environment and human health:
38 RDX targets the nervous system and can cause seizures in humans and animals (Ramasahayam et al.
39 2017) while TNT is considered to be highly toxic and mutagenic (Bolt et al. 2006; Honeycutt et al. 1996;
40 Travis et al. 2008). The US Environmental Protection Agency has classified both RDX and TNT as
41 possible human carcinogens (USEPA, 2014), and during explosives manufacture, transportation, storage
42 and disposal, these toxic pollutants are released into the environment. Additionally, live-fire training at
43 military bases has resulted in the contamination of soils around targets with particulates of munitions
44 compounds, which have leached RDX into the underlying groundwater. The total area of operational
45 ranges in the United States contaminated with munitions constituents is estimated to be more than 16
46 million acres (United States General Accounting, 2004), with clean-up of active ranges estimated by the
47 US Department of Defense to cost between US\$16 billion and US\$165 billion (United States General
48 Accounting, 2004). Chemical-based methods to remediate explosives, such as alkaline hydrolysis
49 (Sviatenko et al. 2017), redox reactions using iron-bearing materials (Oh et al. 2016), and permeable
50 reaction barriers (Ahmad et al. 2007) have proven too cost-intensive for the scale of the contaminated
51 areas. Phytoremediation of RDX and TNT has been developed as a potentially more cost-efficient, and
52 sustainable method to clean up contaminated soil.

53 Plants readily take up and translocate RDX from the soil to the aerial tissues (Vila et al. 2007; Brentner et
54 al. 2010), with studies of poplar (*Populus deltoides* x *nigra* DN-34) showing that RDX can be reduced
55 to hexahydro-1-nitroso-3,5-dinitro-1,3,5-triazine (MNX) and hexahydro-1,3-dinitroso-5-nitro-1,3,5-
56 triazine (DNX) (Van Aken et al. 2004). However, despite high uptake rates, plants have relatively low
57 rates of RDX degradation (Mezzari et al. 2004; Best et al. 1999; Winfield 2004) with RDX accumulated
58 in living plant tissues returning to the environment following plant senescence (Yoon et al. 2006).

59 In contrast to RDX, TNT remains predominantly in root tissues with less than 25 % translocated to aerial
60 tissues (Vila et al. 2007; Brentner et al. 2010). TNT is also more phytotoxic (Pavlostathis and Jackson
61 2002; Hannink et al. 2007; Johnston et al. 2015) than RDX, and symptoms of toxicity such as stunted
62 growth and chlorosis have been observed at concentrations comparable to those found on military training
63 ranges (Pichtel 2012). Plants have a limited ability to detoxify TNT. Endogenous nitroreductases,
64 including oxophytodienoate reductases (Beynon et al. 2009) reduce TNT to hydroxyl-amino and then
65 amino-dinitrotoluenes (HADNTs and ADNTs). These transformed intermediates are then conjugated to
66 hydrophilic molecules such as sugars (Gandia-Herrero et al. 2008) and glutathione (Gunning et al. 2014),
67 then appear to be incorporated into cell wall materials (Rylott and Bruce 2009).

68 While plants are limited in their ability to remediate these explosives, bacteria able to degrade RDX and
69 detoxify TNT have been isolated from explosives-contaminated soils, and the genes responsible
70 characterized: a fused flavodoxin-cytochrome P450 XplA and associated flavodoxin reductase XplB from
71 *Rhodococcus rhodococcus* strain 11Y confer aerobic biodegradation of RDX (Seth-Smith et al. 2002) and
72 from *Enterobacter cloacae*, *nfsI* encodes a nitroreductase (NR), which transforms TNT, favoring the
73 production of the 4-ADNT isomer (Hannink et al. 2001). Numerous species of bacteria containing *xplA*
74 and *xplB* have since been isolated from RDX-contaminated locations around the world (Seth-Smith et al.
75 2008; Rylott et al. 2011b; Andeer et al. 2009; Andeer et al. 2013; Bernstein et al. 2011; Thompson et al.
76 2005; Binks et al. 1995; Coleman 1998; Adrian and Arnett 2004). Yet despite the presence of RDX-
77 degrading bacteria, RDX contamination in these regions persists, suggesting that other limitations are
78 preventing bacterial degradation of RDX.

79 To increase the ability of plants to degrade RDX, *xplA* and *xplB* have been transformed into a range of
80 plant species. The co-pollutant TNT is phytotoxic, and also inhibits XplA activity (Jackson et al. 2007).
81 To overcome these hindering factors, the TNT detoxifying nitroreductase has been expressed in tobacco
82 (*Nicotiana tabaccum*; Hannink et al. 2001), the RDX-metabolizing *xplA* and *xplB* in *Arabidopsis*
83 (*Arabidopsis thaliana*; Rylott et al. 2006); and all three genes have since been simultaneously expressed

84 in *Arabidopsis* (Rylott et al. 2011a), and creeping bentgrass (*Agrostis stolonifera*; Zhang et al. 2017a).
85 These transgenic plants were all able to degrade RDX and resist high levels of TNT when compared to
86 wild-type plants. In our recent report, *nfsI* transformed into the plastid genome of tobacco conferred
87 enhanced resistance to TNT (Zhang et al. 2017b). However, *Arabidopsis*, tobacco, and creeping bentgrass
88 are not well-adapted to thriving in the challenging environments found in military training ranges.
89 Switchgrass (*Panicum virgatum*), is a United States native species, with additional attributes that make it
90 suitable for phytoremediation of explosives on military training ranges, and recently plants have been
91 transformed with *xplA*, *xplB* and *nfsI* and shown to remediate RDX (Zhang et al. 2017a). However, since
92 the range of the lowland switchgrass species is limited, and planting a single species in the field is likely
93 to result in vulnerability to pests, diseases and other environmental stresses; additional grass species are
94 needed. Western wheatgrass (*Pascopyrum smithii*) is a long-lived, cool season, United States native
95 species that is broadly distributed across North America, with characteristics that make it a desirable plant
96 for the phytoremediation of RDX and TNT on live-fire training ranges. Its low maintenance requirements
97 and vigorously spreading rhizomes give it the ability to recover quickly after damage caused by military
98 vehicle traffic, explosive fire or the range fires that occur on training ranges (Palazzo et al. 2005).
99 Furthermore, cultivars, which have improved performance over existing commercially available cultivars,
100 have been developed by the US military specifically for the re-vegetation of ranges including western
101 wheatgrass (Palazzo et al. 2005). However, until now wheatgrass species have proven recalcitrant to
102 transformation. This study uses *xplA*, *xplB*, and *nfsI* to demonstrate an effective transformation protocol,
103 and validate the ability of this species to remediate RDX and TNT.

104 **MATERIALS AND METHODS**

105 **Plasmid construction**

106 The binary vector pEDLZ2014 (Figure 1) was constructed using a protocol similar to that used to
107 transform switchgrass, prcs2-NABNR (Zhang et al. 2017a) with the following modifications. The *Osact*
108 sequence was amplified from pANIC 5A (Mann et al. 2012) and used to replace the 35S promoter in

109 pSAT4a (Tzfira et al. 2005) to produce pNSAT4a. The *xplA*, *xplB* genes (GenBank accession number
110 AF449421 for both), and *nfsI* gene (M63808) were cloned by PCR from the vectors pMLBart-*xplA*,
111 pART27-*xplB*, and pART27-*nfsI* (Rylott et al. 2011a) and inserted into pNSAT3a, pNSAT4a, and
112 pNSAT6a, respectively, to produce pNSAT3a-*xplA*, pNSAT4a-*nfsI*, and pNSAT6a-*xplB* (Zhang et al.
113 2017a). The hygromycin resistance gene, hygromycin B phosphotransferase (*hpt*), was cloned by PCR
114 from pCambia1301 and inserted into pNSAT1a to produce pNSAT1a-*hpt*. The expression cassettes of
115 *OsActin-hpt-35s* T, *ZmUbi-xplA-mas* T, *OsActin-nfsI-35S* T, and *PvUbi-xplB-rbc* T were sequentially
116 inserted into the pRCS2 binary vector at these respective restriction sites *AscI-AscI*, *I-PpoI-I-PpoI*, *I-SceI-*
117 *I-SceI*, *PI-PspI-PI-PspI* to produce pEDLZ2014. All the primers used in this research are listed in
118 Supplement Table 1 and the sequences of all the elements in the vector were listed in Supplement
119 Table 2.

120 **Culture condition for plant materials**

121 Western wheatgrass plants (including callus regeneration, RDX and TNT uptake experiments) were
122 cultured at 25°C under 50 $\mu\text{E m}^{-2} \text{sec}^{-1}$ constant light with a 16 h day/8 h night photoperiod.

123 **Transformation of western wheatgrass**

124 The grain husks of western wheatgrass were removed and the seeds surface-sterilized in 10 % bleach for
125 30 min, then rinsed four times with sterile water. Sterile seeds were cultured on callus induction (CI)
126 medium (Murashige and Skoog's (MS) basic medium (Murashige and Skoog 1962) with 0.5 g/L proline,
127 0.5 g/L N-Z amine, 2.5 mg/L 2,4-dichlorophenoxyacetic acid (2,4-D), 0.1 mg/L 6-benzylaminopurine (6-
128 BAP), 30 g/L sucrose, pH 5.8) in the dark for embryogenic callus induction. The embryogenic calli were
129 sub-cultured onto CI medium at one-month intervals.

130 A biolistic particle system (Bio-Rad PDS-1000) was used for delivery of pEDLZ2014 with 7,584 kPa
131 (1,100 psi) rupture disks, a microcarrier flight distance of 9 cm and a vacuum of 97 kPa (27 in) Hg, with
132 all hardware and reagents produced by Bio-Rad. Microprojectile preparation was as described earlier

133 (Lutz et al. 2006). The embryogenic calli were incubated on osmotic medium (CI medium with 36.4 g/L
134 sorbitol and 36.4 g/L mannitol) for 6 h prior to bombardment. After bombardment, the calli were kept in
135 the dark overnight on osmotic medium, then transferred to CI medium for two days and then to CI
136 medium with 75 mg/L hygromycin. After two months of growth, hygromycin-resistant calli were
137 transferred to fresh selective CI medium for further selection and callus propagation. After three more
138 months of growth, the hygromycin resistant calli were transferred to regeneration medium (MS medium
139 with 1 mg/L 6-BAP, 0.1 mg/L 1-naphthaleneacetic acid (NAA), 30 g/L sucrose, pH 5.8) with 75 mg/L
140 hygromycin. Regenerated plantlets were transferred to MS medium containing 50 mg/L hygromycin, then
141 rooted plantlets transferred to shoot induction medium (MS medium with 2 mg/L 6-BAP, 0.2 mg/L NAA,
142 30 g/L sucrose, pH 5.8) with 50 mg/L hygromycin for cluster shoots induction. After two months, new
143 branches in cluster shoots were excised and transferred to fresh MS medium with hygromycin at 50 mg/L
144 to promote growth and rooting. The rhizomes were cut into sections with a node on each fragment and
145 cultured on MS medium for new plantlet development. One week later, new shoots and roots developed
146 from nodes of rhizomes fragments. Healthy plants from the cluster shoots or rhizomes were selected and
147 transferred to soil.

148 **Transgene expression analysis**

149 DNA was extracted using DNeasy plant mini kits (Qiagen, Valencia, CA, USA), and PCR reactions
150 performed using the primers listed in Table S1. For transcript analysis, mRNA was extracted from mature
151 western wheatgrass leaf blades using RNeasy plant mini kits (Qiagen). One microgram of total RNA was
152 treated with DNase I (Invitrogen) and used to synthesize cDNA with random primers (Invitrogen) and M-
153 MLV reverse transcriptase (Invitrogen). Quantitative real-time PCR (qPCR) was performed using a
154 SensiFast SYBR No-ROX kit (Bioline). Data from RT-qPCR were normalized to the western wheatgrass
155 5.8S gene (GenBank: GU557082.1). Protein analysis used SDS-PAGE with 8 µg of crude protein per
156 sample, and antibodies were used as reported previously, Xp1A, (Rylott et al. 2006); Xp1B, (Jackson et al.
157 2007) and nitroreductase (Rylott et al. 2011a).

158 **RDX uptake studies**

159 Wild-type and transformed plants of comparable biomass and developmental status were selected and
160 cultured in 5 mL ½ MS media with 30 mg/L RDX for 12 days. Levels of RDX in the medium were
161 assayed at regular time intervals, with volumes of medium refilled back to 5 mL with tap water each time
162 before sampling. After 12 days, the RDX concentrations in the plant tissues were determined.

163 **TNT uptake studies**

164 Mature leaf blades were cut into sections about 1.5 cm length and cultured in 20 mL water containing
165 12.5, and 32.5 mg/L TNT. The starting biomass in each bottle was 0.572 ± 0.003 g. Samples of medium
166 were removed at regular intervals for analysis. After 66 hours, the concentrations of TNT and 4-ADNT in
167 the plant tissues were determined.

168 **Extraction of RDX, TNT, and 4-ADNT from plant tissue**

169 Plant leaf tissue (100 mg) was freeze dried and ground to a powder using a Fast Prep 24 (MP
170 Biomedicals, LLC. Solon, USA). RDX, TNT and ADNT were extracted from leaf materials using 1 mL
171 methanol with shaking for 12 hours, then three repeat extractions with shaking for two hours. The
172 combined extraction products were dried using an Eppendorf Vacufuge 5301, re-dissolved in 1.5 mL
173 methanol, centrifuged at 13,000 for ten minutes and the supernatant (1000 µL) analyzed by HPLC.

174 **Determination of RDX, TNT and ADNT levels**

175 RDX, TNT and ADNT concentrations were analyzed using a modular Waters HPLC system consisting of
176 a Waters 717 autosampler, two Waters 515 HPLC pumps, and a Waters 2996 photodiode array detector.
177 A 4.6- by 250-mm Waters C18 column was used for separation under conditions similar to those
178 described previously (Andeer et al. 2013), with concentration determined based on absorbance at 240 nm.
179 Peak integrations and analyses were conducted using Millennium32 software (Waters, Milford, MA). The
180 limit of detection of RDX by this method is 0.01 mg/L.

181 **Data analysis**

182 Data were analyzed for statistical significance using ANOVA in Microsoft Excel software (Microsoft
183 Excel 2016 MSO). When ANOVA analysis gave a significant difference, Fishers Least Significant
184 Difference (LSD) method was performed to compare the means. Groupings differing by statistical
185 significance are labeled by letters in the figures.

186 **RESULTS**

187 **Creation of transgenic western wheatgrass**

188 Following results from the expression of *xplA*, *xplB*, and *nfsI* in switchgrass and creeping bentgrass, the
189 vector used in our former report (Zhang et al. 2017a), was modified to improve transgene expression. The
190 35S promoter driving expression of *nfsI* was replaced with the rice (*Oryza sativa*) actin promoter (*Osact*);
191 and the switchgrass ubiquitin promoter (*Pvubi*) driving *xplA* expression was replaced with the maize (*Zea*
192 *mays*) ubiquitin promoter (*ZmUbi*). The structure of the resulting vector, pEDLZ2014, is shown in
193 Figure 1.

194 To successfully transform western wheatgrass, vigorously-growing embryogenic calli were needed.
195 Figure 2a shows the white or light-yellow, friable embryogenic calli obtained after 1-2 months of growth.
196 Following additional culturing, calli suitable for transformation were obtained (Figure 2b) and bombarded
197 with pEDLZ2014 vector DNA. Figure 2c shows the appearance of the surviving calli two months after
198 bombardment; after three to four months, green and healthy plantlets were obtained (Figure 2d). In total,
199 10 plates of embryogenic calli were bombarded, with 98 calli showing hygromycin resistance and of
200 these, 30 produced green and healthy plantlets (Figure 2e). To produce biomass for subsequent analysis,
201 the plantlets were propagated on cluster shoot induction medium which initiated the formation of robust
202 shoots and rhizomes as shown in Figure 2f. The rhizomes were cut into nodal sections, as shown in
203 Figure 2g, and cultured to regenerate new plantlets. Figure 2h shows the appearance of the fully
204 regenerated plants in soil.

205 To confirm the integration and expression of the transgenes in the hygromycin-resistant plantlets, PCR
206 and qRT-PCR analysis were conducted on thirteen, independently-transformed lines. The results,
207 presented in Figure 3a, show expression of *xplA*, *xplB* and *nfsI* in the transgenic lines, while the
208 transgenes were not detectable in the wild-type, untransformed plants. Expression of the transgenes was
209 highest in lines S35, N1, N9 and D22 and subsequent western blot analysis (Figure 3b) of these lines
210 revealed the presence of 60, 45 and 24 kDa bands, which corresponded in size to the XplA, XplB and NR
211 proteins, respectively.

212 **RDX uptake studies**

213 To determine the rate of RDX uptake, the plants were grown in liquid MS medium in open test tubes.
214 Evaporation of RDX from the medium was minimal due to its low volatility (Xiong et al. 2009). Over the
215 course of the experiment, all the transformed lines removed RDX from the medium faster than the wild-
216 type plants (Figure 4a). After 3 days, the RDX concentration in the medium containing transformed plants
217 was significantly lower than that of wild-type plants ($p = 2 \times 10^{-6}$). After 6 days, the difference between
218 wild-type and transformed lines further increased with lines N9 and D22 removing significantly more
219 RDX than lines S35 and D45 ($p = 0.0003$). After 12 days of culture, 65 % of the RDX had been removed
220 by wild-type plants while 86 % and 87 % by line N9 and D22 respectively. After 12 days, wild-type RDX
221 leaf tissue levels were found to be 0.12 ± 0.03 mg/g RDX, in comparison, RDX was not detected in tissue
222 from transformed lines tested, N9, D22, and S35, and RDX was at 0.033 ± 0.001 mg/g in transformed line
223 D45 (Figure 4b). To confirm that the lack of accumulation of RDX in transformed tissue was caused by
224 degradation, rather than by dilution in growing plant tissues, leaf blades of wild-type and lines, N9 and
225 D22 were cultured in water with 20 mg/L or 40 mg/L RDX. Figure 4c shows that while the concentration
226 of RDX in the wild-type leaves increased from day 2 to day 8, no RDX was detected in the transformed
227 line D22. Although RDX was detected in leaf tissue of transformed line N9, it was 28 % lower than that
228 in wild-type ($p = 0.004$) at day 2 when cultured in RDX solution at 20 mg/L, and 53% lower ($p = 0.033$)
229 at day 2, with 40 RDX mg/L. In contrast to wild-type, the RDX concentration in line N9 decreased after 2

230 days of culture and could not be detected on day 8. This result confirmed that both N9 and D22 are able to
231 degrade RDX.

232 **TNT detoxification studies**

233 Though the main target of this research was to engineer grasses for RDX degradation, the grasses also
234 need to be able to resist the phytotoxicity of TNT since training ranges are contaminated by both RDX
235 and TNT, and TNT can also inhibit XplA activity (Jackson et al. 2007). Thus the *xplA-xplB-nfsI*
236 transformed lines N9, and D22, which had the highest RDX degradation abilities, were tested for their
237 resistance to TNT conferred by NR activity. When leaf sections were cultured in water containing 15
238 mg/L TNT, the transformed lines removed TNT more quickly than wild-type plants ($p = 0.0019$ at 18 hr
239 incubation). Line D22 removed TNT most rapidly, with TNT undetectable in the solution after 48 hr.
240 After 66 hr, nearly all TNT had disappeared from solution from wild-type and transformed plants (Figure
241 5a). Though wild-type western wheatgrass removed TNT from the solution, when compared to the
242 transgenic lines after 66 hr, the wild-type leaf sections exhibited symptoms of toxicity, with overall
243 yellowing of the leaf surfaces and darkening of the cut edges (Supplement Figure 1a). After 66 hours of
244 culture in water containing 32 mg/L TNT, the wild-type plants were unable to remove any TNT, while the
245 transformed lines removed nearly all the TNT (0.38 ± 0.16 mg/L remaining for N9 and 0.51 ± 0.35 for
246 D22; Figure 5b). Furthermore, the wild-type plants showed signs of toxicity, as indicated by a reduction
247 in growth rate such that the biomass gain of wild-type was 24 % and 30 % of that of N9 and D22,
248 respectively after 3 days (Supplement Figure 1b).

249 While in whole plants, TNT and transformation products are localized predominantly in the roots, when
250 grown in liquid culture, leaf tissues are known to also contain these products (Hannink et al. 2007;
251 Hannink et al. 2001). To verify that TNT was transformed in the tissues of the modified plants, TNT and
252 ADNT levels, in leaf tissue were determined after 42 hours culture in TNT solution (Figure 5c). When
253 cultured in 12.5 mg/L TNT solution, TNT was not detected in the tissues of either wild-type or
254 transformed plants, while ADNT was detected in wild-type leaf tissue at a level lower than for N9 and

255 D22 ($p = 0.0188$). When cultured in 25 mg/L TNT solution for 42 hours, the wild-type leaf tissue
256 accumulated 11.91 ± 1.64 $\mu\text{g/g}$ TNT, about 3 times of that in lines N9 and D22 ($p = 0.0004$). At the same
257 time, the ADNT concentration in the wild-type plants was 6.01 ± 0.92 $\mu\text{g/g}$, about 60 % of that in leaf
258 tissue of transformed plants ($p = 0.0012$). These results demonstrated that though wild-type plants have
259 the ability to uptake and detoxify limited amounts of TNT, the *nfsI*-transformed western wheatgrass are
260 able to detoxify significantly more TNT, resulting in increased tolerance, and subsequent ability to take
261 up overall more TNT.

262 **DISCUSSION**

263 On live-fire training ranges, deposition of RDX and TNT onto soils around targets is ongoing and thus a
264 continuing source of soil and groundwater contamination. Phytoremediation could be a relatively low-
265 cost method to contain and clean-up these sites but many plant species grow poorly in RDX and TNT
266 contaminated soil (Vila et al. 2007; Via and Zinnert 2016; Panz and Miksch 2012; Via et al. 2015) and are
267 not able to degrade significant amounts of RDX (Best et al. 1999; Yoon et al. 2006; Best et al. 2006).

268 Studies in model plant species have demonstrated that genetically modifying plants with *xplA*, *xplB* and
269 *nfsI* conferred the ability to degrade RDX and detoxify TNT (Hannink et al. 2007; Rylott et al. 2011a).

270 The subsequent development of genetically modified switchgrass and creeping bentgrass confirmed that
271 this system for RDX degradation worked efficiently in monocot grasses (Zhang et al. 2017a). However,
272 expression of the *nfsI* gene, under the control of the 35S promoter, in these lines was poor, and
273 accordingly, the transformed switchgrass did not show enhanced resistance to TNT. Expression of the
274 35S promoter has been reported to be lower in monocots (Jang et al. 2002; Christensen et al. 1992). In
275 this research, the 35S promoter driving the expression of *nfsI* was replaced with the monocot *OsAct*
276 promoter. The resulting western wheatgrass plants showed both enhanced RDX degradation and
277 enhanced TNT detoxification.

278 Western wheatgrass has many desirable attributes that make it suitable for deployment on training ranges.
279 It is native to the US, growing across a broad geographical location with includes military lands (USDA,
280 2002). Furthermore, its robust leaves and rhizomes make it able to withstand stresses associated with
281 military ranges such as fire, military vehicular traffic, and nutrient poor soils. Some of these attributes
282 also make western wheatgrass valuable as a forage grass, so advances in its genetic modification are
283 important in agriculture. Here we describe a method for reliably transforming western wheatgrass. This
284 method could also be adapted to other forage grasses, such as slender wheatgrass (*Elymus trachycaulus*)
285 and Siberian wheatgrass (*Agropyron fragile*). In our experience, a prerequisite for successful development
286 of transformed callus is the selection of the friable white callus morphology (Figure 2b).

287 In conclusion, this is the first report on the genetic transformation of western wheatgrass. This protocol
288 will contribute to wider plant biotechnology uses, here, we utilize it to show the efficacy of *xplA*, *xplB*,
289 *nfsI*-expressing plants to degrade RDX and detoxify TNT. These species neatly complement transgenic
290 switchgrass lines, enabling this technology to be used across a broader range of environmental, and
291 geographic conditions for the containment and detoxification of explosives on military training ranges.
