Keywords: Subject-specific finite element analysis; digital volume correlation; shoulder FEM; CT-compatible loading.

33 **Abstract**

34 Subject-specific finite element models (FEMs) of the shoulder complex are commonly
35 used to predict differences in internal load distribution due to injury, treatment or disease.
36 However, these models rely on various underlying assumptions, and although experimental
37 validation is warranted, it is difficult to obtain and often not performed. The goal of the current
38 study was to quantify the accuracy of local displacements predicted by subject-specific QCT-based
39 FEMs of the scapula, compared to experimental measurements obtained by combining digital
40 volume correlation (DVC) and mechanical loading of cadaveric specimens within a microCT
41 scanner.

42 Four cadaveric specimens were loaded within a microCT scanner using a custom-designed
43 six degree-of-freedom hexapod robot augmented with carbon fiber struts for radiolucency.
44 BoneDVC software was used to quantify full-field experimental displacements between pre- and
45 post-loaded scans. Corresponding scapula QCT-FEMs were generated and three types of boundary
46 conditions (BC) (idealized-displacement, idealized-force, and DVC-derived) were simulated for
47 each specimen.

48 DVC-derived BCs resulted in the closest match to the experimental results for all
49 specimens (best agreement: slope ranging from 0.87 - 1.09; highest correlation: r^2 ranging from
50 0.79-1.00). In addition, a two orders of magnitude decrease was observed in root-mean-square
51 error when using QCT-FEMs with simulated DVC-derived BCs compared to idealized-
52 displacement and idealized-force BCs.

53 The results of this study demonstrate that scapula QCT-FEMs can accurately predict local
54 experimental full-field displacements if the BCs are derived from DVC measurements.

55 **1. Introduction**

56 Subject-specific finite element models (FEMs) of the shoulder complex provide the capability to
57 predict the internal load distribution of the joint. Although quantitative computed tomography
58 (QCT)-derived FEMs have been accepted as an established research tool to further understand the
59 mechanics of the shoulder (Allred et al., 2016; Terrier et al., 2005; Zheng et al., 2017), the accuracy
60 of predictions generated by these models is to some extent unknown. Currently, experimental
61 validation of QCT-FEMs of the shoulder is limited to localized predictions of strain on the cortical
62 shell (Dahan et al., 2016; Gupta et al., 2004); while the accuracy of internal predictions within the
63 trabecular bone has yet to be explored.

64 To observe the internal load distribution within human bone, recent experimental protocols
65 have combined mechanical loading with simultaneous time-lapsed volumetric imaging of bone
66 specimens undergoing deformation (Nazarian and Müller, 2004). Digital volume correlation
67 (DVC) techniques have been introduced to quantify full-field localized displacement
68 measurements between pre- and post-loaded volumetric images (Grassi and Isaksson, 2015;
69 Roberts et al., 2014). In addition, previous experimental studies that have combined volumetric
70 imaging with DVC analysis techniques have shown great promise to elucidate internal fracture
71 mechanisms by quantifying progressive strain and damage evolution within composite materials
72 (Croom et al., 2016, 2019, 2017). To acquire volumetric images of a deformed specimen, a CT-
73 compatible loading device is required. Current CT-compatible joint loading devices are based on
74 screw-type mechanisms and are restricted by the degrees-of-freedom (dof) of load they can apply
75 (Du et al., 2015; Jackman et al., 2016; Martelli and Perilli, 2018; Palanca et al., 2016; Sukjamsri
76 et al., 2015; Zhou et al., 2018). However, to properly replicate physiological joint loads at the
77 shoulder complex, a 6-dof loading mechanism would be desirable. Regardless, current

78 experimental protocols developed with DVC techniques have shown tremendous promise by
79 quantifying internal localized deformations within trabecular bone that otherwise cannot be
80 captured experimentally (Bay et al., 1999; Chen et al., 2017; Gillard et al., 2014; Liu and Morgan,
81 2007).

82 DVC has been applied at the micro (*e.g.* trabecular bone cores) and joint level (*e.g.*
83 vertebra) to validate μ CT- and QCT-FEMs respectively (Chen et al., 2017; Costa et al., 2017;
84 Hussein et al., 2018; Jackman et al., 2016; Mao et al., 2019, p.; Zael et al., 2005). At the micro
85 level, the accuracy of the predictions generated by μ CT-FEMs was found to be sensitive to the
86 boundary condition (BC) modelled (Chen et al., 2017). Specifically, when using BCs derived
87 directly from local DVC measurements, any inherent experimental limitations (*e.g.* specimen
88 fixation rigidity or structural stiffness of the loading mechanism) were assumed to be eliminated
89 and thus excellent agreement (slope (m) ≈ 1 , coefficient of determination (r^2) ≈ 1 , y-intercept (b)
90 ≈ 0) was achieved (Chen et al., 2017; Costa et al., 2017; Oliviero et al., 2018). However, when
91 extrapolating these techniques to QCT-FEMs at the joint level, similar success has not been
92 reported. Previous studies performed by Jackman *et. al.* and Hussein *et. al.* within the vertebra
93 found improvements in performance of QCT-FEMs when using BCs derived from DVC
94 measurements obtained at the yield point; but only moderate agreement between the experimental
95 local displacements and FEM predictions were observed (Hussein et al., 2018; Jackman et al.,
96 2016). A similar validation study has yet to be performed to quantify the performance of shoulder
97 QCT-FEMs in predicting local experimental displacement measurements obtained through DVC.

98 Hence, the primary objective of the current study was to quantify the accuracy of local
99 displacements predicted by subject-specific shoulder QCT-FEMs compared to experimental
100 measurements obtained through mechanical loading and simultaneous volumetric imaging of

101 cadaveric scapular specimens. A secondary objective was the design and fabrication of a CT-
102 compatible 6-dof loading apparatus capable of applying articular loads within a microCT scanner.

103 **2. Materials and Methods**

104 **2.1 *Development of a CT-Compatible 6-DOF Loading Apparatus***

105 A custom 6-dof hexapod parallel robot was designed to apply external loads to a scapula. The
106 robot consisted of a base, loading platform and six prismatic actuators that connected the base and
107 platform (Figure 1) in a configuration consistent with a Stewart platform design. Although
108 variations exist, the Stewart platform design commonly uses six linear actuators attached in pairs
109 by universal joints to a movable platform and fixed base. Each prismatic actuator is composed of
110 a lead screw mechanism driven by independent servo-motors. Although the robot consisted of only
111 linear actuators, its hexapod configuration transforms linear displacements into complete 6-dof
112 motions that include all possible translations and rotations, within its range of motion. In addition,
113 the Stewart platform design is noted to have a high load carrying capacity within a small working
114 envelope and has been used in previous applications involving 6-dof biomechanical testing
115 applications (Boyin Ding et al., 2011; Lawless et al., 2014; Walker and Dickey, 2007).

116 The hexapod robot was augmented with radiolucent carbon fiber extensions to provide CT-
117 compatibility with a Nikon XT H 225ST cone-beam microCT scanner. Custom fixtures were
118 fabricated to allow for loads to be applied to the glenoid of a cadaveric scapula within a microCT
119 scanner. A hemispherical platen (diameter equal to 48 mm) was fabricated from acetal plastic and
120 attached to the loading platform via an acrylic extension rod. A 6-dof load cell (Mini 45, ATI
121 Industrial Automation, NC, USA) was instrumented to the loading platform to provide real-time

122 force feedback during the experimental loading protocol. Overall, the current system can apply 1.5
123 kN of compression and weighs 9.6 kg.

Figure 1: A custom-designed six degree-of-freedom hexapod robot was used to experimentally load cadaveric scapulae within a cone-beam microCT scanner. The use of carbon fiber struts provided radiolucent sections to reduce any imaging artifacts that may occur with use of the hexapod robot.

124

125 **2.2 Specimen Preparation and Experimental Loading**

126 Four cadaveric shoulders (two male and two female) were tested (Table 1). Prior to experimental
127 loading, the specimens with soft tissue intact were imaged within a clinical QCT-scanner (GE
128 Discovery CT750 HD, Milwaukee, WI, USA) at clinical scan settings (pixel size: 0.625 mm to
129 0.668 mm, slice thickness: 0.625 mm, 120 kVp, 200 mA, BONEPLUS). A dipotassium phosphate
130 (K₂HPO₄) calibration phantom (QCT Pro, Mindways Software Inc., Austin, TX, USA) was
131 included in each QCT scan for specimen-specific QCT-density relationships. QCT scans obtained

132 at clinical resolution were used for development of continuum-level QCT-derived finite element
 133 models described further in Section 2.4. Following the scanning protocol, each scapula was
 134 denuded of all soft tissue. The glenoid articular surface was resurfaced using a clinical shoulder
 135 reaming tool to provide a consistent uniform surface for experimental loading. The scapula was
 136 then cut on a medial plane (sectioned approximately 55 mm from the articular surface) and
 137 cemented in polymethyl methacrylate (PMMA) for fixation in the hexapod robot. A custom jig
 138 was used to orient the axis at which the glenoid was resurfaced perpendicular to the loading
 139 platform of the hexapod robot.

140 Table 1: Age, sex, and QCT density (± 1 SD) of cadaveric scapulae specimens.

	Sex	Age	QCT Density ($\text{g}_{\text{K}_2\text{HPO}_4}/\text{cm}^3$)
Specimen 1	Male	80	0.333 ± 0.256
Specimen 2	Male	73	0.245 ± 0.198
Specimen 3	Female	62	0.376 ± 0.240
Specimen 4	Female	52	0.377 ± 0.253

141 Experimental loading for each scapula was performed within a cone-beam microCT
 142 scanner (Nikon XT H 225ST). Each specimen was wrapped with tissue-soaked phosphate-buffered
 143 saline solution to ensure hydration throughout the scanning protocol. The hexapod robot,
 144 previously described, was used to apply external loads. Consistent for each specimen, an initial
 145 stabilizing load (10 N, settling time of 20 minutes to allow for specimen relaxation) was applied
 146 and a pre-loaded microCT scan was acquired (33.5 μm isotropic voxel size, 95 kVp, 64 μA , 3141
 147 projections, 55 minute scan time, 1000 ms exposure). Two post-loaded scans of the specimen were
 148 then obtained with identical settings as the pre-loaded scan. The first load consisted of a target
 149 compressive load of 500 N with a settling time of 20 minutes. The second load consisted of a target
 150 500 N load applied off-axis, 5° posterior for each specimen and 5° inferior for specimens 1, 2, and
 151 4 with respect to the robot's frame. An inferior off-axis angle was not applied to specimen 3 due

152 to interference between the acrylic extension rod and the acromion of the specimen. Both loading
153 cases were performed directly within the microCT scanner, without repositioning the loading
154 apparatus between scans. Load cell measurements were acquired via a NI-USB 6210 data
155 acquisition unit (National Instruments Corporation, Austin, Texas) obtained after the 20 minutes
156 settling time but prior to the microCT scan. The resulting field of view (FOV) for each scan was a
157 cube with edge lengths of 65 mm, which captured the glenoid vault (approximately 25 mm medial
158 from the articular surface) and the loading platen in the pre- and post-loaded states.

159 **2.3 *Digital Volume Correlation***

160 Local experimental displacement measurements between the pre- and post-loaded images were
161 obtained using DVC algorithms (Figure 2). To prepare the images for DVC, a specimen-specific
162 threshold was applied (Mimics v.20.0, Materialise, Leuven, BE) to segment and isolate the glenoid
163 vault from other objects captured within the microCT scans (*e.g.* loading platen). Values outside
164 the selected threshold were assigned a constant grey level value similar to bone marrow (equivalent
165 to 85 in 8-bit greyscale). The images were then cropped and converted to 8-bit greyscale (ImageJ,
166 NIH) (Schneider et al., 2012).

167 A previously established and validated deformable image registration toolkit, BoneDVC,
168 was used to quantify the full-field experimental displacement field between the pre- and post-
169 loaded images (Dall'Ara et al., 2017, 2014). BoneDVC is a global based DVC approach that
170 computes full-field local displacement vectors between two sets of volumetric images using cross
171 correlation techniques (Dall'Ara et al., 2014). Furthermore, BoneDVC has previously been used
172 to validate μ FEMs for various osseous structures (Chen et al., 2017; Costa et al., 2017; Oliviero et
173 al., 2018). To compute the precision of the local displacement measurements quantified by

174 BoneDVC, a standard procedure of comparing two pre-loaded scans with various nodal spacing
 175 was performed (Dall’Ara et al., 2017, 2014). Based on these results, a nodal spacing of 30 voxels,
 176 (approximately 1 mm), was decided as an optimal tradeoff between spatial resolution and precision
 177 (error along x, y, and z direction lower than 2.5 μm).

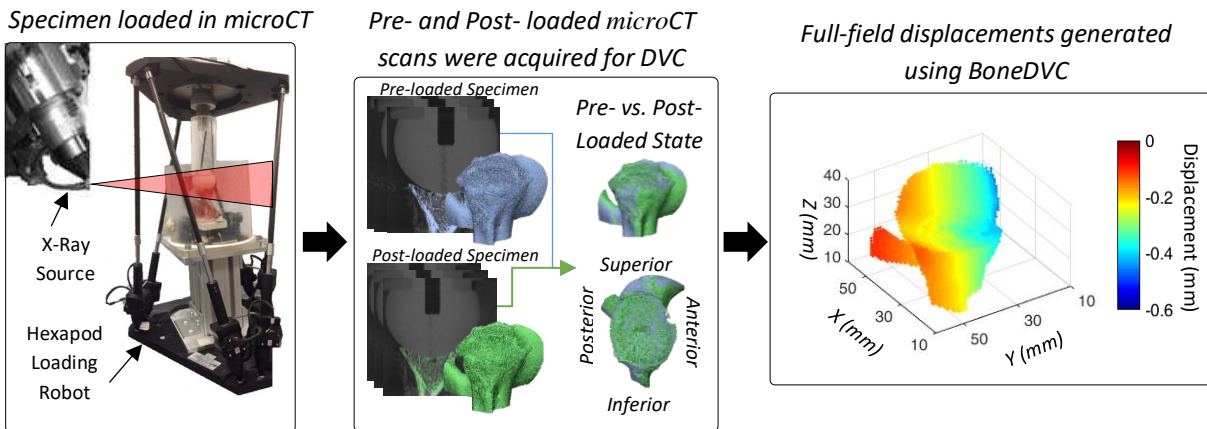

Figure 2: Four scapula specimens were scanned within a microCT at a resolution of 33.5 μm in pre- and post-loaded states. Full-field local displacements (sub-volume size ≈ 1 mm) between the pre- and post-loaded scans were obtained using BoneDVC.

178

179 2.4 Computational In-Silico Modelling

180 Specimen-specific QCT-FEMs were generated for each scapula to simulate the experimental
 181 loading set-up. The geometry of each scapula was extracted from the corresponding QCT scan
 182 acquired prior to experimental loading. To identify the medial border at which the experimental
 183 scapulae were cut, laser surface scans (Artec Spider, Artec 3D, Luxembourg) were acquired for
 184 each prepared specimen. From these, STL models were generated and registered to the QCT
 185 models. Anything below the PMMA surface was removed by Boolean subtraction. In addition,
 186 any elements within the volume of the reamed articular surface were removed to match the
 187 prepared cadaveric scapulae. A surface triangular mesh was generated (3-matic v.12.0,
 188 Materialise, Leuven, BE) with a target edge length of 1 mm (Burkhart et al., 2013). The surface

189 mesh was then converted to a quadratic tetrahedral mesh using ABAQUS (v.6.14, Simulia,
190 Providence, RI). Linear elastic isotropic material properties were applied to the volumetric mesh
191 (Mimics v.20.0, Materialise, Leuven, BE) based on the local density measure using Eq.1 and Eq.
192 2 (Rice et al., 1988; Schaffler and Burr, 1988).

$$\rho_{app} < 1.54 \text{ g/cm}^3 \quad E_{trab} = 60 + 900 * \rho_{app}^2 \quad (\text{Eq. 1})$$

$$\rho_{app} \geq 1.54 \text{ g/cm}^3 \quad E_{cort} = 90 * \rho_{app}^{7.4} \quad (\text{Eq. 2})$$

193 Where E_{trab} is Young's modulus of trabecular bone [MPa], E_{cort} is Young's modulus of cortical
194 bone [MPa], and ρ_{app} is apparent density.

195 To register the QCT-FEMs to the coordinate system of the microCT, an iterative closest points
196 algorithm (3-matic Research 11.0, Materialise, Leuven, BE) was performed aligning the outer
197 geometry of the QCT-derived scapula to the corresponding microCT-derived scapula (Knowles et
198 al., 2019).

199 Three separate boundary conditions (BCs) were modelled (ABAQUS v.6.14, Simulia,
200 Providence, RI) to investigate their effect on the accuracy of the QCT-FEMs. The first two
201 simulations consisted of idealized BCs (idealized-displacement BC and idealized-force BC). For
202 both idealized BCs, a deformable virtual loading platen, meshed with hexahedral elements ($E =$
203 3100 MPa , $\nu = 0.35$), was constructed and general contact between the virtual platen and scapula
204 was modelled (coefficient of friction = 0.2). The medial border of the scapula was assumed to be
205 fixed and either a force (idealized-force BC) or displacement (idealized-displacement BC) was
206 applied to the virtual loading platen (Figure 3). For the idealized-force BC, the experimental force
207 measured immediately prior to the microCT scan was prescribed to the top nodes of the virtual
208 loading platen. For the idealized-displacement BC, a displacement was prescribed to the top nodes
209 of virtual loading platen forcing the platen to the post-loaded experimental position. The

210 experimental post-loaded position of the loading platen was quantified by segmenting out the
211 experimental platen in the corresponding raw post-loaded microCT image.

Figure 3: Specimen-specific QCT-FEMs with idealized BCs were modelled. Idealized BCs assumed the medial border of the scapula was fixed and either a displacement (idealized-displacement) or force (idealized-force) was applied to the virtual loading platen.

212

213 In addition, DVC-derived BCs were modelled (Chen et al., 2017; Costa et al., 2017;
214 Jackman et al., 2016; Zuel et al., 2005) (Figure 4). First, to generate the DVC-derived BCs, each
215 specimen was further cropped medially due to the limited FOV of the microCT scans.
216 Subsequently, local displacements were prescribed to each node lying on the articular surface of
217 the glenoid and the medial surface of the cropped scapula. A custom Matlab code (v.R2017a,
218 Mathworks, Natick, MA) applied tri-linear interpolation to local displacements provided by the
219 DVC measurements onto the corresponding QCT-FEM nodes.

Figure 4: DVC-derived BCs were modelled by assigning local experimental displacements obtained by DVC directly to the articular and medial surface of the QCT-FEM scapula.

220

221 2.5 Statistical Analysis

222 To quantify the performance of the scapula QCT-FEMs, local displacement predictions were
 223 compared to DVC experimental measurements using linear regression. To pair the outcome
 224 measures, local DVC displacements were paired with averaged QCT-FEM predicted
 225 displacements, region averaged within a 1mm cubic voxel, equivalent to the DVC nodal spacing
 226 and dependent on the nodal location of the DVC measurement (Hussein et al., 2018; Jackman et
 227 al., 2016). Furthermore, to exclude any measurements prescribed by the DVC-derived BCs, only
 228 nodes within the middle 80% of the scanned specimen were used for comparison. Outliers were
 229 removed from the paired QCT-FEM predictions and local DVC results along the x, y, and z
 230 direction using 5x the Cook's distance (Costa et al., 2017). Slope (m), coefficient of determination
 231 (r^2) and root-mean-square error (RMSE) were quantified for both loading conditions (compressive
 232 and off-axis) and with each BC (idealized-force, idealized-displacement, and DVC-derived).

233 In addition, reaction forces predicted by the QCT-FEMs with idealized-displacement BCs
234 and DVC-derived BCs were compared to the experimental applied force. Idealized-force BCs was
235 not included, as the input force required to generate the model was equal to the experimentally
236 measured force. Absolute percentage error was quantified for each specimen and for both loading
237 cases.

238 **3. Results**

239 The accuracy of predictions generated by the QCT-FEMs was found to be highly sensitive to the
240 boundary conditions simulated. For all four specimens subjected to the compressive load, the
241 performance of QCT-FEMs in predicting experimental local displacements were vastly improved
242 with DVC-derived BCs (Table 2, Figure 5). DVC-derived BCs resulted in the closest match to the
243 experimental results, with ranges of $m = 0.93 - 1.05$, $b = -0.02 - 0.01$, and $r^2 = 0.83 - 1.00$ for each
244 specimen along the x, y, and z direction. Similar agreement between the experimental and QCT-
245 FEM predictions were not obtained when using idealized BCs. High variations within m ($-0.13 -$
246 1.66), b ($-0.09 - 0.28$) and r^2 ($0.002 - 0.93$) were observed for QCT-FEMs with idealized-force
247 BCs. In addition, high variations in m ($-0.03 - 2.84$), b ($-0.29 - 0.75$), and r^2 ($0.001 - 0.95$) were
248 observed when using idealized-displacement BCs for all specimens. Overall, RMSE was decreased
249 by two orders of magnitude when using DVC-derived BCs (average RMSE of $4.1 \pm 0.9 \mu\text{m}$, $4.7 \pm 2.2 -$
250 μm , $4.8 \pm 2.3 \mu\text{m}$ along x, y, and z direction respectively) compared to the idealized-force BC
251 (average RMSE of $414 \pm 479 \mu\text{m}$, $401 \pm 356 \mu\text{m}$, $331 \pm 170 \mu\text{m}$ along x, y, and z direction
252 respectively) and idealized-displacement BC (average RMSE of $367 \pm 342 \mu\text{m}$, $322 \pm 273 \mu\text{m}$,
253 $175 \pm 96 \mu\text{m}$ along x, y, and z direction respectively).

254 Table 2: Linear regression results between local displacements predicted by QCT-based FEMs and
 255 DVC experimental results due to a compressive load.

Specimen #		Slope (m)			y-intercept (b)			Coefficient of Correlation (r^2)			Root Mean Square Error (RMSE) (μm)		
		x	y	z	x	y	z	x	y	z	x	y	z
Idealized-Force BC	1	0.52	0.21	0.11	0.12	0.08	0.00	0.89	0.38	0.10	237	447	234
	2	-0.02	-0.10	-0.13	0.00	0.07	-0.09	0.01	0.59	0.47	37	866	565
	3	0.01	0.31	0.10	0.02	-0.07	-0.02	< 0.01	0.50	0.48	1117	274	248
	4	1.05	1.66	0.88	0.28	-0.01	0.17	0.93	0.82	0.77	265	18	199

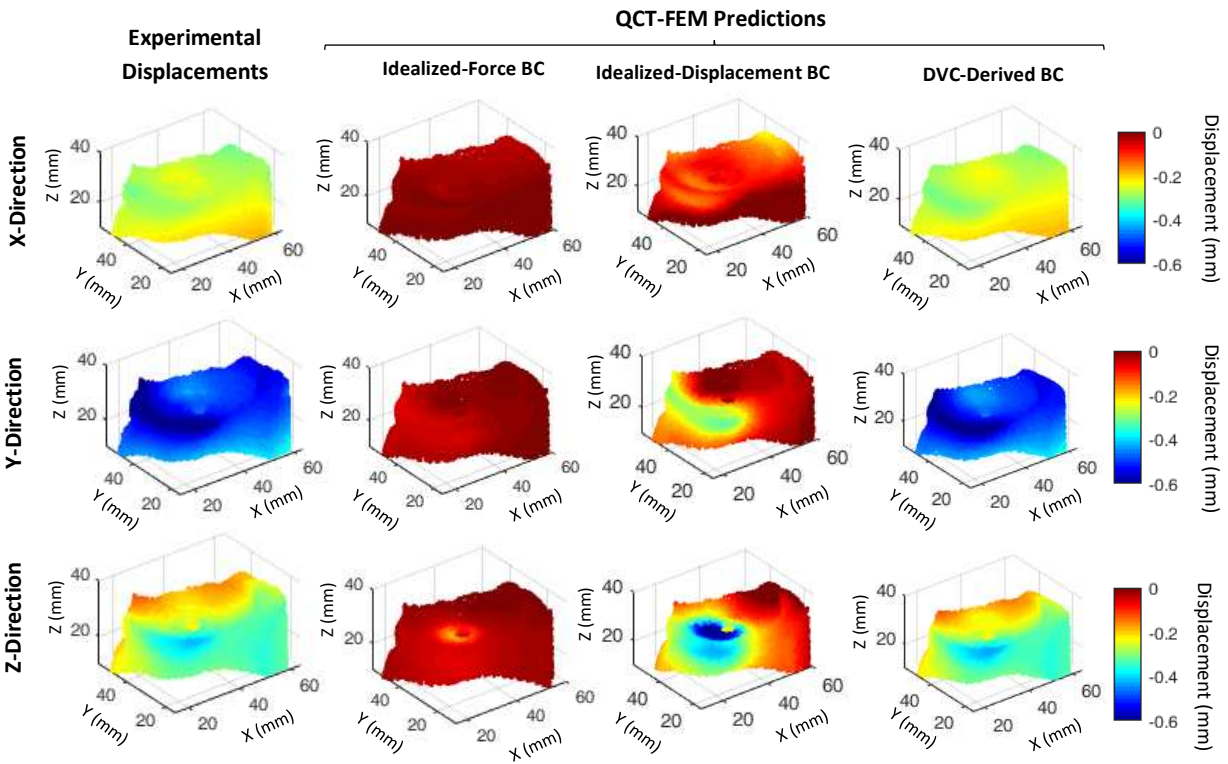

Figure 5: Representative full-field experimental displacements for specimen 1 during a compressive load, compared to predictions generated by a QCT-FEM with idealized-force BC, idealized-displacement BC, and DVC-derived BC.

257 For the off-axis load, similar results to the compressive load were observed (Table 3). High
 258 variability in m (ranges $-0.40 - 2.35$), b ($-0.70 - 0.98$), and r^2 ($0.002 - 0.98$) were observed for both
 259 idealized BCs. However, when using DVC-derived BCs, excellent agreement with the
 260 experimental results were obtained with ranges of m ($0.87 - 1.09$), b ($-0.03 - 0.03$), and r^2 ($0.79 -$
 261 1.00) for each specimen. In addition, RMSE between the QCT-FEM predictions and experimental
 262 measurements was greatly reduced when using DVC-derived BCs (average RMSE of $4.8 \pm 0.7 \mu\text{m}$,
 263 $5.3 \pm 1.0 \mu\text{m}$, $6.0 \pm 1.4 \mu\text{m}$ along x , y , and z direction) compared to idealized-force BC (average
 264 RMSE of $541 \pm 268 \mu\text{m}$, $443 \pm 681 \mu\text{m}$, $337 \pm 225 \mu\text{m}$ along x , y , and z direction) and idealized-
 265 displacement BC (average RMSE of $494 \pm 343 \mu\text{m}$, $345 \pm 484 \mu\text{m}$, $196 \pm 147 \mu\text{m}$ along the x , y , and
 266 z direction).

267 Table 3: Linear regression results between local displacements predicted by QCT-based FEMs and
 268 DVC experimental results due to an off-axis load.

Specimen #	Slope (m)			y-intercept (b)			Coefficient of Correlation (r^2)			Root Mean Square Error (RMSE) (μm)

269 High percentage errors (average error = 333%, range = 169 - 429%) in reaction forces were
 270 required to displace the virtual loading platen when using idealized-displacement BCs.
 271 Comparatively, the percentage error was reduced when using QCT-FEMs with DVC-derived BCs
 272 (average error = 32%, range = 8 - 44%). Similar results were observed with an off-axis load, with

273 higher percentage errors when using idealized-displacement BCs (average error = 350%, range =
274 152 - 520%) compared to DVC-derived BCs (average error = 26%, range = 6 - 50%).

275 **4. Discussion**

276 The goal of the current study was to quantify the performance of scapula QCT-FEMs in predicting
277 local displacement measurements obtained from combining digital volume correlation (DVC) and
278 mechanical loading within a microCT scanner. Due to the inability to resolve trabecular
279 microarchitecture at a resolution associated with clinical *in-vivo* imaging of bone, QCT-FEMs rely
280 on continuum-level assumptions and ignore the geometry of the inner trabecular network.
281 However, the accuracy of local predictions generated by subject-specific vertebra QCT-FEMs has
282 recently been questioned (Hussein et al., 2018; Jackman et al., 2016). The results of the current
283 study found that QCT-FEMs of the scapula can accurately predict local displacement
284 measurements when using DVC-derived BCs. A two orders of magnitude decrease was observed
285 in RMSE, when using QCT-FEMs with simulated DVC-derived BCs compared to the idealized
286 BCs during a compressive or off-axis load. Furthermore, excellent agreement (m ranging from
287 0.87 - 1.09, r^2 ranging from 0.79 - 1.00) was found between experimental results and QCT-FEM
288 predictions when using DVC-derived BCs, consistent with previous studies performed using μ -
289 FEMs on different bone structures (Chen et al., 2017; Costa et al., 2017; Oliviero et al., 2018).
290 Reaction forces predicted by the QCT-FEMs with DVC-derived BCs were also within reasonable
291 error (compressive error range 8 - 44%, off-axis error range 6 - 50%). The excellent performance
292 of the QCT-FEMs with DVC-derived BCs within the current study may partly be attributed to the
293 fact that loading only within the elastic range was performed, simplifying the QCT-FEMs
294 generated, compared to step-wise fracture loading previously performed (Hussein et al., 2018;
295 Jackman et al., 2016). In addition, inherent differences between the vertebra and scapula, and their

296 constitutive equations used to assign material properties may contribute to the performance
297 differences in QCT-FEMs of this study compared to previous vertebral studies. Therefore,
298 although excellent agreement between the QCT-FEM predictions and DVC results were observed
299 within the current study in the shoulder, it is unknown whether these findings can be extrapolated
300 to QCT-based FEMs of other joints.

301 To perform cadaveric experimental loading within a microCT, a secondary objective
302 included the design of a CT-compatible loading device. The robot's ability to generate articular
303 loads within a small working envelope overcame a major design constraint imposed by space
304 restrictions within a CT scanner. Furthermore, controlled loading in 6-dof is a marked
305 improvement over previously developed screw-based CT-compatible devices (Jackman et al.,
306 2016; Martelli and Perilli, 2018; Palanca et al., 2016; Sukjamsri et al., 2015). Precision of the DVC
307 measurements was found not to be affected by the hexapod robot, as errors $< 2.5 \mu\text{m}$ along each
308 Cartesian direction were recorded during the repeated scans procedure further demonstrating the
309 feasibility of the apparatus.

310 For QCT-FEMs with idealized-force BCs, local displacement predictions generally
311 underestimated the experimental results. In addition, computed reaction forces required to displace
312 the virtual platen were much higher in QCT-FEMs with idealized-displacement BCs compared to
313 idealized-force BCs. This may suggest that the QCT-FEMs may have been too stiff due to over-
314 constrained idealized BCs. Only stiffness of the specimen mount (including the PMMA cement)
315 is relevant, since the experimental displacement was measured from microCT rather than from the
316 apparatus itself. Potentially, local DVC displacement measurements could have been applied to
317 the bottom surface of the idealized QCT-FEMs and this may have reduced the observed
318 differences; however, this would require localized displacement measures as an input into the

319 QCT-FEMs that may not always be attainable. Nonetheless, stiffness of the experimental setup
320 was not accounted for in this study, as the idealized BCs were modelled according to the literature
321 (Chen et al., 2017; Jackman et al., 2016). Now that it has been observed that QCT-FEMs with
322 DVC-derived BCs can in fact replicate experimental displacement measures, future work could
323 include modelling the experimental apparatus to allow for the QCT-FEMs to become more
324 generalizable.

325 Limitations within the current study should be noted. First, QCT-FEMs were only validated
326 using linear-isotropic material properties subjected to elastic loads. Therefore, further validation
327 is required to investigate failure mechanisms that arise due to loading within the inelastic region.
328 Furthermore, only local displacement measurements and global reaction forces were used to
329 quantify the performance of scapula QCT-FEMs. While strain is a commonly used metric
330 produced by QCT-FEMs to predict failure, experimental strains calculated from microCT-based
331 DVC displacements exhibit higher uncertainties. As the scope of the current study only included
332 evaluating local displacements and global reaction forces, the impact of boundary conditions on
333 other local outcome predictions such as strain was not explored. A Synchrotron light source could
334 be used which may reduce experimental uncertainties (Comini et al., 2019; Palanca et al., 2017);
335 however, this was outside the scope of the current study. Finally, the low sample size ($n = 4$) of
336 this study is a limitation, which was a product of the complex and time-consuming loading and
337 imaging protocol.

338 The results of the study demonstrate that errors in local displacements predicted by QCT-
339 FEMs of the shoulder can be minimized using DVC-derived boundary conditions. This work also
340 demonstrated that a novel CT-compatible hexapod robot design was effective for applying 6-dof
341 loading vectors to a scapula while acquiring high-resolution microCT scans in a cone beam

342 scanner. Combining volumetric imaging with DVC analysis allowed for the ability to evaluate
343 full-field internal displacement predictions generated by the QCT-FEMs that otherwise could not
344 be captured with traditional surface-based measurement techniques (Dahan et al., 2016; Lin et al.,
345 2016). Further development of these methods should be conducted to examine fracture
346 mechanisms.

347 **Acknowledgements**

348 The authors would like to thank Aoife Pucchio for her assistance with data collection. This research
349 was supported by a Post Graduate Scholarship from the Natural Sciences and Engineering
350 Research Council of Canada. Jonathan Kusins and Nikolas Knowles are supported in part by a
