Model Checking of State-rich Formalism Circus by Linking to $CSP \parallel B$

Kangfeng Ye · Jim Woodcock

Received: March 3, 2015 / Revised version: September 18, 2015

Abstract Since state-rich formalism Circus is a combination of Z, CSP, refinement calculus and Dijkstra's guarded commands, its model checking is intrinsically more complicated and difficult than that of individual state-based languages or process algebras. Current solutions translate executable constructs of *Circus* programs to Java with JCSP, or translate them to CSP processes. Data aspects of Circus programs are expressed in the Java programming language or as CSP processes. Both of them have disadvantages. This work presents a new approach to model-checking Circus by linking it to $CSP \parallel B$, then we utilise ProB to model-check and animate the $CSP \parallel B$ program. The most significant advantage of this approach is the direct mapping of the state part in Circus to Z and finally to B, which maintains the high-level abstraction of data specification. In addition, introduction of deadlock, invariant violation checking, LTL formula checking and animation is another key advantage. We present our approach, a link definition for a subset of Circus constructs, as well as a popular case study (reactive buffer) to show the practical usability of our work. We conclude with a discussion of related work, advantages and potential limitations of our approach, and future work.

Keywords *Circus* \cdot *CSP* \parallel *B* \cdot CSP \cdot Z \cdot B \cdot ProB \cdot Model Checking \cdot Buffer

1 Introduction

In the last two decades, the advent of model checking [14], a technique used for the verification of a finite-state system by automatically and exhaustively checking whether the model meets a given specification, has been getting ever increasing interest from both industry and academia. Verification of systems specified using formal methods by model checking is one among these. Comparing to theorem proving, another technique for formal verification, the advantages of model checking, including an automated checking procedure, counterexamples for debugging, and the capability of temporal logic properties checking, make it very important for a formalism to support both model checking and theorem proving in a complementary way.

Traditional research in formal methods often focuses on two schools: state-based, model-oriented specification languages such as Z [47], B [5] and VDM [26]; and behaviouroriented process algebras such as CSP [25, 43], CCS [32] and ACP [8]. But in recent decades, there is an increasing research interest in specification languages that integrate both state and behavioural aspects. Early solutions aim to combine them together, such as CSP-OZ [18], ZCCS [23], Z and CSP [34, 44], and CSP $\parallel B$ [46]. Fischer gave a summary of combination solutions of Z and process algebras [19]. However, state-rich formalism *Circus* [49] is not a simple combination of Z and CSP. It is a combination of Z, CSP, refinement calculus [33] and Dijkstra's guarded commands [16]. Therefore, its model checking is intrinsically more complicated and difficult than that of individual Z and CSP. The complexity of model checking *Circus* is increased due to two main factors. The first one is state space explosion challenge. Basically, the state of a system specified by Circus is the state of its processes. However, for each process it may contain state and behaviour, and consequently its state is a combination of both variable state and action state. In addition, the process's variable and action states are dynamically constructed and destroyed along with invocation and destroy of the process. It possibly has infinite number of distinct states as well. Because of this hierarchical structure of Circus and possible infinite states, how to represent and search its state space including infinite state space and infinite data type efficiently is really a challenge. Another factor is Circus's very rich notations from Z, CSP and guarded commands. Along with its powerful expressiveness and high-level abstraction, all make the development of its model checker—to parse and typecheck Circus programs, check deadlock and livelock, check refinement in terms of Circus action refinement and data refinement, and CSP failure-divergence refinement-difficult. In addition, the relationship between state and behaviour in early solutions is always orthogonal during development. Therefore, they can use the existing tools for each school separately. However, for Circus its syntax is a free mixture of CSP and Z. As a result it cannot use current Z and CSP tools directly.

Our proposed approach to model-check *Circus* in this paper is to link *Circus* to $CSP \parallel B$ that integrates state and behaviour through synchronization of operations. On the one hand, the state part in *Circus* is transformed to the B machine. On the other hand, the behavioural part is converted to CSP. The resultant CSP and B specifications maintain highlevel abstraction of the initial *Circus* specification because they are specification languages rather than programming languages. Accordingly, it is more direct and powerful to specify the state part in B than in CSP. Furthermore, the final $CSP \parallel B$ can be model-checked by ProB [3], a model checker and animator for multiple languages. Apart from these, with ProB we introduce LTL and CTL [14] property checking, automatic and manual animations, and refinement checking into *Circus* specification.

Our contribution is to define a formal link from Circus to $CSP \parallel B$. With this link, we take the model checking into Circus by model-checking $CSP \parallel B$ using ProB. Additionally, to establish the link between them, we studied the transformation from Z in ISO Standard [4] dialect to Z in ZRM [47] and finally to B, and the transformation of Circus expressions from ISO Standard Z to CSP as well. The soundness of the link from Circus to the intermediate CSP and Z in ZRM is proved based on their semantics in Hoare and He's Unifying Theories of Programming (UTP) [24]. We also studied the correctness of the link from Z in ZRM to B though it relies on the implementation of ProB. Furthermore, because of the expressiveness and high-level abstraction of Circus, it is impossible to define an inverse link from $CSP \parallel B$ to Circusand achieve exactly the same Circus constructs as the original constructs. Hence, our link is one direction only from Circus to CSP \parallel B and can not form Galois connections [24].

The rest of the paper is structured as follows. We give a brief introduction of *Circus* and $CSP \parallel B$ in Sect. 2. Then in Sect. 3, the link function, its decomposition and overall strategies are described. Afterwards, Sect. 4 presents a subset of rules for each link function. A case study of a buffer is undertaken in Sect. 5 to illustrate how our approach works. Finally, in Sect. 6, we discuss related work, our work's pros and cons, and future work.

2 Background

2.1 Circus

The BNF syntax of *Circus* is shown in Figure 1. A *Circus* program consists of a sequence of paragraphs: Z paragraph, channel declaration, channel set definition or a process definition. A category, that is decorated with an additional star, such as **CircusPar***, denotes a possibly empty list of **CircusPar**, while a category decorated with an additional plus, such as **N**⁺, denotes a non-empty list of Z identifiers **N**. **Par**, **SchemaExp**, **Exp**, **Pred** and **Decl** represent Z paragraphs, schema expressions, expressions, predicates and declarations defined in the reference manual [47] respectively.

A Circus paragraph can be a Z paragraph, a channel declaration, a channel set declaration, or a process declaration. A channel declaration is very similar to that in CSP except a schema channel declaration which merely groups the channel declarations into the schema. And a channel set declaration relates a name to a set of channels. Additionally a process can be defined in the process declaration as a parametrised process (Decl • ProcDef), an indexed process, an explicitly defined process (**begin** \cdots **state** $\cdots \bullet A$ **end**), or a compound process which is defined in terms of CSP operators or the indexed operator (|i|). In particular, the indexed process $(IP \stackrel{\frown}{=} i : T \odot P)$ is new to *Circus*. For its instantiation IP|e|, it behaves like P, but for each channel c in P, it is changed to c_i.e. In addition, a process renaming operator $(P[c_{old} := c_{new}])$ substitutes the channels in c_{new} for the channels in c_{old} in the process P.

An explicitly defined process is composed of a state schema, which declares a set of state components in the process, multiple schemas and action declarations (possibly none of them), a main action, which defines the behaviour of this process. An action can be a schema expression (SchExp), a command, an action defined in terms of CSP. And a command can be an assignment (:=), an alternation $(\mathbf{if} \cdots \mathbf{fi})$, a guarded command $(g) \otimes A$, a variable block $(\mathbf{var} Decl \bullet A)$, a parametrisation by value (\mathbf{val}) , by result (\mathbf{res}) and by value-result (\mathbf{vres}) , a specification statement ([]), an assumption $(\{\})$, or a coercion ([]). Particularly, for CSP actions, the parallel composition $(A_1 [[ns_1 | cs | ns_2]] A_2)$ where ns_1 and ns_2 are the state partitions of the actions A_1 and A_2

Fig. 1: Syntax of Circus

separately) and the interleaving $(A_1 || [ns_1 | ns_2] || A_2)$ in *Circus* are slightly different. Both A_1 and A_2 have a copy of all variables in scope and may change the value of these variables. But only the changes made to the variables in ns_1 and ns_2 have an effect in the final state of the parallel composition and the interleaving. Furthermore, state components and local variables in an action can be renamed by a renaming operator $(A[v_{old} := v_{new}])$.

A simple buffer [12] specification in *Circus* is illustrated in Figure 2. The size of the buffer is bounded by maxbuff, a global constant declared in the axiomatic paragraph. Afterwards, two typed channenls input and output are declared to allow only natural number on their communications. Then an explicitly defined process named Buffer is defined. This process has two state variables buff and size. And the initial state of the process is an empty buffer where buff is an empty sequence and size is equal to 0. In addition to the state schema and the initial schema, there are two schemas InputCmd and OutputCmd defined as well. They are invoked by their corresponding schema expressions (InputCmd) and (OutputCmd) in the actions Input and Output respectively. The behaviour of *Buffer* is specified by its main action: it is initialized to the initial state; after that, it provides input (in case the buffer is not full) and output (in case the buffer is

```
section BufferSpec parents circus_toolkit  | maxbuff : \mathbb{N}_1  channel input, output : \mathbb{N} process Buffer \widehat{=} begin state State ==[buff: seq \mathbb{N}: size: 0 \dots maxbuff | size = \#buff \le maxbuff] Init ==[(State)'|buff'=\langle\rangle \land size'=0] InputCmd ==[\Delta State: x?: \mathbb{N}|size < maxbuff \land buff'=buff'\langle x? \rangle \land size'=size+1] OutputCmd ==[\Delta State|size>0 \land buff'=tailbuff \land size'=size-1] Input \widehat{=}(size < maxbuff) \otimes input?x \rightarrow (InputCmd) Output \widehat{=}(size > 0) \otimes output!(head buff) \rightarrow (OutputCmd)
\bullet (Init); (\mu X \bullet (Input \square Output); X) end
```

Fig. 2: The Specification of Buffer

not empty) events to its environment continuously. Accordingly, it buffers the input message in its end and increases its size by one, or outputs its head and decreases its size by one

Additionally, since *Circus* is a combination of several different languages that have different semantics, there arises an issue about how to unify its semantics into one. For

example, CSP-OZ introduces the failures-divergences model [43] into Object-Z [11] classes and then integrates CSP processes with Object-Z classes based on the same failures-divergences semantics. But $CSP \parallel B$ treats a B machine as a CSP process, and gives CSP traces, stable failures and failures-divergences semantics to B machines [46]. *Circus* needs to combine not only Z and CSP, but also the guarded command language and the refinement calculus. *Circus* formalises its model in UTP because UTP is a common framework for the unification of programs from different paradigms. Denotational semantics [37, 38, 49] and operational semantics [22,51,52] of *Circus* have been given.

2.2 Unifying Theories of Programming

UTP is a unified framework to form theoretical basis for describing and specifying computer languages across different paradigms such as imperative, functional, declarative, nondeterministic, concurrent, reactive and high-order. A theory in UTP is described from three parts: *alphabet*, a set of variable names for the theory to be studied; *signature*, rules of primitive statements of the theory and how to combine them together to get more complex program; and *healthiness conditions*, a set of mathematically provable laws or equations to characterise the theory.

The alphabetised relational calculus [13] is the most basic theory in UTP. A relation is defined as a predicate with undecorated variables (v) and decorated variables (v') as its alphabet. v denotes the observation made initially and v' denotes the observation made at the intermediate or final state. The behaviour of a design is described from initial observation and final observation by relating precondition P to postcondition P as $P = \frac{1}{2} (P + Q) = \frac{1}{2}$

But a reactive process cannot be characterised from the final observation alone because it interacts with its environments (other programs and users). It must take intermediate states into account. Therefore, three extra variables and their dashed counterparts are introduced: tr and tr', the sequences of the events occurred; ref and ref', the sets of events that may be refused; wait and wait', the boolean variables that denote whether the process has terminated (true) or is in an intermediate state (false). Cavalcanti and Woodcock [13] lift the theory of reactive processes to CSP processes. "CSP processes are reactive; moreover they are R-image of designs" [13, Figure 1, p.257]. The reactive processes are expressed as the reactive design ($R(P \vdash Q)$).

2.3 Combination of CSP and B

 $CSP \parallel B$ [9] is a combination of CSP and B aiming to introduce behavioural specification into state-based B machines. The B method characterises abstract state, operations with respect to their enabling conditions, and their effect on the abstract state, while CSP specifies overall system behaviour. But different from *Circus*, the CSP specification and B machine in $CSP \parallel B$ are always orthogonal. They are individually complete specifications and can be checked separately.

Semantically the combination of CSP and B works in terms of CSP. The B machine, which has operations Ops $(\{Op_1,\ldots,Op_n\})$ and variables $Vars(\{v_1,\ldots,v_m\})$, is regarded as a process B_{proc} (1). The operation Op_i is enabled if its precondition holds or $enabled(Op_i)$ is true. CSP may have all or part of events from the events $Ops(\{Op_1,\ldots,Op_n\})$ that have the same name as operations Ops in B. CSP and B processes are composed together by a generalised parallel composition in CSP, as shown in (2). B and CSP synchronise on events Ops in CSP and operations Ops in B. If an event Op_i in Ops is allowed by the CSP specification and at the same time the operation Op_i in B is enabled as well, then they can make progress. After that, the state Vars of the B machine, which are specified in the predicate of operation Op_i , are updated. Otherwise, if Op_i is not allowed at the same time as Op_i is enabled, neither of them can make progress. In addition, for events only in CSP and not having corresponding operations in B, they engage independently. Conversely, for operations only specified in B and not in CSP, they are prevented from executing. If none of operations required by CSP specification are enabled or the CSP process is blocked, then the $CSP \parallel B$ program is deadlocked. Consequently no state can be changed and no event can be

$$B_{proc} \stackrel{\frown}{=} \mu X \bullet \begin{pmatrix} (Op_1 \to X) & \text{denabled}(Op_1) & \text{STOP} \\ \Box \dots \\ \Box (Op_n \to X) & \text{denabled}(Op_n) & \text{STOP} \end{pmatrix}$$

$$(1)$$

$$CSP \parallel B = (CSP \parallel_{Ops} B_{proc}) \setminus \{|Ops|\}$$
 (2)

2.4 ProB

ProB is a model checker and animator developed by the University of Düsseldorf originally for the B language. It has been extended to support a variety of formal specification languages, such as Z, CSP, Event-B [6], TLA+ [27], Promela and $CSP \parallel B$. Particularly, the dialect of Z supported is ZRM [47] and the syntax of CSP is written in CSP_M [45]. The main functions of ProB include temporal logic and refinement model checking, deadlock and invariant violation checking with counterexamples available, au-

tomatic and manual animations, visualisation of state spaces and test-case generation. Its kernel is written in SICStus Prolog [10]. Most importantly, its source code is open and licensed under EPL v1.0 [17].

3 Link Definitions

3.1 Overall Link Function

A function Υ (pronounced "upsilon") is defined to map a *Circus* program to a *CSP* \parallel *B* program.

Circus
$$\stackrel{\Upsilon}{=\!=\!=\!\to} CSP \parallel B$$

The overall strategies of Υ are defined.

- Fundamentally, the state part of *Circus* is linked to a B machine and the behavioural part to a CSP specification.
 Some constructs such as command actions, which specify both state and behaviour, are mapped to constructs in both B and CSP.
- The definitions, such as type definitions, abbreviation and axiomatic definitions, are mapped to the counterparts in B and possibly in CSP if they are referred to in the behavioural part of *Circus*.
- State components in *Circus* are mapped to variables in B.
 However, since state components are encapsulated in explicitly defined processes, they are merged to form variables in B when mapped.
- Operational schemas within an explicitly defined process, which includes the state schema in its declaration and is not included by other schemas, are mapped to operations in B. However, these operations are restricted to manipulate variables that are mapped from state components of the same processes in *Circus*, and never change variables that are mapped from state components of different processes.
- Channel declarations are mapped to channel declarations in CSP.
- The main action of an explicitly defined process is mapped to a same name process in CSP.
- Compound processes are linked to the same name processes in CSP.

3.2 \(\gamma \) Function Decomposition

Because a *Circus* program is linked to a *CSP* \parallel *B* program with a complete B machine and a CSP specification, we decompose the Υ function into two functions: Ω (pronounced "omega") function and Φ (pronounced "phi") function. The Ω function is responsible for the translation of the state part in *Circus* to B, while the Φ function is for that of the behavioural part to CSP.

However, *Circus* itself is not a simple combination of the CSP and Z languages but a free mixture of CSP and Z with additional guarded commands. An exact example is the assignment command that may specify both state and behaviour. For instance, this action (3) inputs a value x over c channel, then the assignment command updates the state variable s to s plus the local variable s. In this action, state and behaviour are mixed together. As a result, s and s functions cannot apply to the original *Circus* program directly.

$$c?x \to s := x + l \tag{3}$$

Thus, another function, named R_{wrt} , is defined. It aims to rewrite a *Circus* program to separate the state and behavioural parts into Z and CSP. The action (3) is rewritten to an action and a schema (4) according to the R_{wrt} Rule 7 which is defined latter. Finally, Ω and Φ can be easily applied to this rewritten *Circus* program.

$$c?x \to (AssOp)$$
 (4)

where
$$AssOp == [\Delta P _StPar; l? : T_{l?}; x? : T_c \mid s' = x? + l?]$$

The relation of Υ function decomposition is displayed in Figure 3. In a rewritten Circus program, state and behaviour are separate. No construct will specify both state and behaviour at the same time. The interaction between them highly depends on schema expressions. The original schemas and schema expressions in Z and behaviour respectively are still kept in the rewritten program. In addition, it is worth noting that additional operational schemas are added in Z, and any direct state components accessed and updated in *Circus* actions will rely on schema expressions. Furthermore, for other constructs such as commands, they are rewritten to additional schemas and their schema expressions as well. Finally we state that the rewritten Circus program has the same structure as the original program, which means state components of each process are still encapsulated in its own process.

3.2.1 Ω Function Decomposition

For the Ω function, our strategy is to reuse the currently available solution [41] in ProB to translate Z in ZRM to B. Considering this strategy, we map the state part of the *Circus* program to ISO Standard Z first because *Circus* itself is written in ISO Standard Z, then to Z in ZRM, and finally from ZRM to B by ProB. Accordingly, the Ω function is decomposed as well: the Ω_1 function translates the state part in Z in a rewritten *Circus* specification to a complete specification in ISO Standard Z by merging all state components and schemas from all processes; the Ω_2 function syntactically transforms Z in ISO Standard Z to that in ZRM; the Ω_3 function, translation function from ZRM to B, is implemented in ProB and stated in Daniel Plagge et al.'s work [41].

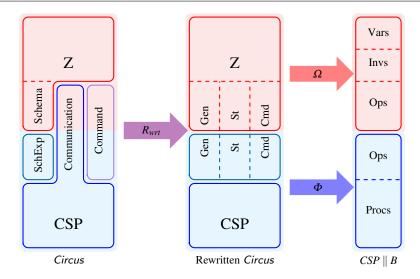

Fig. 3: Translation Function (Υ) Decomposition

3.3 Link Strategies

In addition to the overall strategies and link functions, some other strategies are defined.

- Every rule defined for Υ is sound unless stated otherwise. The soundness of the map is based on UTP semantics. If the corresponding linked constructs in $CSP \parallel B$ have the same semantics as the original constructs in Circus, then the link is sound.
 - From the design perspective, a design $P_1 \vdash Q_1$ is equal to another design $P_2 \vdash Q_2$ if, and only if, $(P_1 = P_2) \land (P_1 \Rightarrow (Q_1 = Q_2))$. If both designs have the same alphabets (ok, v), and their dashed counterparts), the same preconditions that imply the equal postcondition, we say they are semantically equal.
 - From the reactive process (R(P⊢Q)) perspective, if both reactive processes have the same alphabets (ok, wait, tr, ref, v, and their dashed counterparts), the same preconditions that imply the equal postcondition and the same other observation variables, we say two reactive processes are semantically equal.
 - For state-based specification languages such as Z and B, their semantics are specified in the designs of UTP.
 But for CSP and the behavioural part of *Circus*, their semantics are specified in the reactive theory of UTP.
- State components of *Circus* are maintained in a Z specification and finally a B machine. Thus we require they are updated only in the B machine but can be accessed in both B and CSP programs. The CSP specification will not maintain states. If a process in the CSP specification needs to get the value of variables in B, it shall retrieve them through a communication between CSP and B.

4 Link Rules

4.1 Identifiers

In ISO Z Standard, an identifier is a DECORWORD that is composed of WORD and STROKE [4, 8.4]. Stokes (', !, and ?) are very important part in Z specification. They may denote dashed variables, input variables and output variables within a schema. In addition, they may form the schema decoration and binding construction expressions as well. A word can be a keyword, operator or name. In addition to letter, digital and underscore (_), a name may have other special symbols such as subscript and superscript.

However, the pattern of an identifier or name in CSP_M and B, $[a-zA-Z][a-z A-Z0-9_]$ [15,20], is limited. It begins with an alphabetic character ([a-zA-Z]) and are followed by any number of alphanumeric characters or underscores. Particularly, for CSP_M , it can be optionally followed by prime characters ($^{\circ}$).

Therefore, we restrict the pattern used in *Circus* for a name the same as that in CSP_M and B. But for strokes, they are necessary and specially treated when translating to CSP_M and B.

4.2 Circus Rewriting Function - R_{wrt}

The R_{wrt} function is defined to rewrite *Circus* constructs to facilitate the application of the Φ function and the Ω function in the later stage.

 R_{wrt} Rule 1 (Parametrised Process) For the parametrised process, it is expanded to a number of explicitly defined processes, provided that T in (5) is finite and has n elements: x_1 ,

..., x_n . The number of explicitly defined processes is equal to the cardinality of T.

$$R_{wrt} \left(\mathbf{process} \ PP \stackrel{\frown}{=} x : T \bullet P \right)$$

$$= \begin{pmatrix} R_{wrt} \left(\mathbf{process} \ PP \mathcal{L}_1 \stackrel{\frown}{=} P[x_1/x] \right) \\ \dots \\ R_{wrt} \left(\mathbf{process} \ PP \mathcal{L}_n \stackrel{\frown}{=} P[x_n/x] \right) \end{pmatrix}$$
(5)

where the substitution notation $P[x_1/x]$ denotes the expression x_1 consistently substituted for free occurrences of the variable x in P.

 R_{wrt} Rule 2 (Indexed Process) An indexed process (6) is rewritten to a parametrised process with all its channels renamed at first, then it is expanded to a number of explicitly defined processes by the parametrised process rule (5).

$$R_{wrt} \left(\mathbf{process} \ IP \ \widehat{=} \ i : T \odot P \right)$$

$$= R_{wrt} \left(\mathbf{process} \ IP \ \widehat{=} \ i : T \bullet P[c := c \ .i .i] \right)$$

$$= \begin{pmatrix} R_{wrt} \left(\mathbf{process} \ IP \ .i_1 \ \widehat{=} \ (P[c := c \ .i .i])[i_1/i] \right) \\ \dots \\ R_{wrt} \left(\mathbf{process} \ IP \ .i_n \ \widehat{=} \ (P[c := c \ .i .i])[i_n/i] \right) \end{pmatrix}$$

$$= \begin{pmatrix} R_{wrt} \left(\mathbf{process} \ IP \ .i_1 \ \widehat{=} \ P[c := c \ .i .i_1] \right) \\ \dots \\ R_{wrt} \left(\mathbf{process} \ IP \ .i_n \ \widehat{=} \ P[c := c \ .i .i_n] \right) \end{pmatrix}$$

$$(6)$$

where $P[c := c_i.i]$ denotes the renaming of each channel c in P to $c_i.i$.

 R_{wrt} Rule 3 (Renaming Operator) The renaming operator $P[c_{old} := c_{new}]$ renames the channel c_{old} in P to the channel c_{new} .

$$R_{wrt}(P[c_{old} := c_{new}]) = (F_{Ren}(P, \{(c_{old}, c_{new})\}))$$
(7)

where $F_{Ren}(P, \{x, y\})$ is a renaming function that replaces occurrences of the term x in P to the term y.

R_{wrt} Rule 4 (Indexed Process with Renaming) In Circus, the indexed process notation is commonly used with the renaming operator together to define more expressive processes. Therefore,

$$\begin{split} R_{wrt}\left(\left(\mathbf{process}\ IP \ \widehat{=}\ i: T \odot P\right) \left[c \lrcorner i := d\right]\right) \\ &= R_{wrt}\left(\left(\mathbf{process}\ IP \ \widehat{=}\ i: T \bullet P\left[c := c \lrcorner i.i\right]\right) \left[c \lrcorner i := d\right]\right) \\ &= \begin{pmatrix} R_{wrt} \left(\begin{array}{c} \mathbf{process}\ IP \lrcorner i \ \widehat{=} \\ \left(\left(P\left[c := c \lrcorner i.i\right]\right) \left[i_1/i\right]\right) \left[c \lrcorner i := d\right] \\ \dots \\ R_{wrt} \left(\begin{array}{c} \mathbf{process}\ IP \lrcorner i \ \widehat{=} \\ \left(\left(P\left[c := c \lrcorner i.i\right]\right) \left[i_n/i\right]\right) \left[c \lrcorner i := d\right] \\ \end{pmatrix} \end{pmatrix} \end{split}$$

$$= \begin{pmatrix} R_{wrt} \begin{pmatrix} \mathbf{process} \ IP . i_1 \ \widehat{=} \\ (P[c := c . i . i_1]) \ [c . i := d] \end{pmatrix} \\ \dots \\ R_{wrt} \begin{pmatrix} \mathbf{process} \ IP . i_n \ \widehat{=} \\ (P[c := c . i . i_n]) \ [c . i := d] \end{pmatrix} \end{pmatrix}$$

[Substitution]

$$= \begin{pmatrix} R_{wrt}(\mathbf{process} \ IP_i_1 \stackrel{\frown}{=} P[c := d.i_1]) \\ \dots \\ R_{wrt}(\mathbf{process} \ IP_i_n \stackrel{\frown}{=} P[c := d.i_n]) \end{pmatrix} [R_{wrt} \ \text{Rule 3}]$$

For explicitly defined processes, the R_{wrt} function is to separate the state part and the behavioural part as well as renaming of state components, schema paragraphs and action paragraphs. Consequently, all interactions between state and behaviour are through schema expressions only.

R_{wrt} Rule 5 (Additional State Components Retrieve Schemas) The rule for state components retrieve schemas is shown in Figure 4, where B function denotes the body of the action. For each state component in an explicitly defined process, one schema is added to retrieve the value of this state component. The name of the output variable in this schema is composed of the state component name and !. And its type is the same as the type of the state component.

R_{wrt} Rule 6 (Renaming of State Components, Schemas, Actions and their References) The rule for renaming is shown in Figure 5. State components, schema paragraphs, action paragraphs, and each reference to them within an explicitly defined process are renamed by prefixing the process's name. The only exception is that the reference to state components in action is not changed.

 R_{wrt} Rule 7 (Action Rewriting) The rule for action rewriting is illustrated in Figure 6, where $P_{-}assOp$ (8) is a schema added in the process of this assignment. The definitions of R_{pre} and R_{post} functions are given in Definition 1. To rewrite the external choice, a R_{mrg} function is provided to merge the rewriting prefixes of both actions and it is defined in Definition 2. Note that it is not syntactically correct in Circus because schema expression actions cannot be a channel event in communication. But when schema expression actions are translated to events in CSP, it is valid in the final CSP $\parallel B$.

$$P_assOp == [\Delta P_StPar; l? : T_{l?}; l! : T_{l!} | P_s' = (e_s[l?/l]) \land l! = (e_l[l?/l])]$$
(8)

Definition 1 (R_{pre} and R_{post}) Rewriting an action to get the value of state components in its first construct, $R_{wrt}(A)$, is composed of $R_{pre}(A)$ and $R_{post}(A)$ which denotes the prefix (state components retrieve schema expressions) and the remaining respectively: $R_{wrt}(A) = R_{pre}(A) \rightarrow R_{post}(A)$. For

$$R_{wrt} \begin{pmatrix} \mathbf{process} \ P \cong \mathbf{begin} \\ \mathbf{state} \ StPar = = [s_1 : T_1 ; \cdots s_n : T_n \mid p] \\ Pars = = [\cdots] \\ APars \cong B(APars) \\ \bullet \ A \\ \mathbf{end} \\ \end{pmatrix}$$

$$\bullet \ A \\ \mathbf{end}$$

$$= \begin{pmatrix} \mathbf{process} \ P \cong \mathbf{begin} \\ \mathbf{state} \ StPar = = [s_1 : T_1 ; \cdots s_n : T_n \mid p] \\ Pars = = [\cdots] \\ Op_s_1 = [\Xi StPar ; s_1! : T_1 \mid s_1! = s_1] \\ \cdots \\ Op_s_n = [\Xi StPar ; s_n! : T_n \mid s_n! = s_n] \\ APars \cong B(APars) \\ \bullet \ A \\ \mathbf{end} \end{pmatrix}$$

Fig. 4: Additional Schemas for State Components Retrieve

example,

$$R_{pre}(\mathbf{Skip}) = R_{post}(\mathbf{Skip}) = \mathbf{Skip}$$

$$R_{pre}(\mathbf{Stop}) = R_{post}(\mathbf{Stop}) = \mathbf{Stop}$$

$$R_{pre}(c!s_i!...!s_j \to A) = (OP_s_i) \to \cdots \to (OP_s_j)$$

$$R_{post}(c!s_i!...!s_j \to A) = c!s_i!...!s_j \to R_{wrt}(A)$$

$$R_{pre}(g) = (OP_s_i) \to \cdots \to (OP_s_j)$$

$$R_{post}(g) = g$$

provided the condition g evaluates state components s_i, \ldots, s_j , and OP_s_i is the schema name for state component s_i .

Definition 2 (R_{mrg}) A R_{mrg} $(R_{pre}(A_1), R_{pre}(A_2))$ function is defined to merge the rewriting prefixes of A_1 and A_2 into one final prefix. Basically, it is equal to $R_{pre}(A_1) \rightarrow R_{pre}(A_2)$ if each state component retrieve schema expression in $R_{pre}(A_2)$, (OP_s_i) , is different from any in $R_{pre}(A_1)$. However, for any state component retrieve schema expression in $R_{pre}(A_2)$, if it is the same as that in $R_{pre}(A_1)$, it is removed from $R_{pre}(A_2)$ before combination. For example,

$$R_{mrg}\left(\left(OP_{-x}\right),\left(OP_{-y}\right)\right) = \left(OP_{-x}\right) \to \left(OP_{-y}\right)$$

$$R_{mrg}\left(\left(OP_{-x}\right),\left(OP_{-y}\right) \to \left(OP_{-x}\right)\right)$$

$$= \left(OP_{-x}\right) \to \left(OP_{-y}\right)$$

4.3 Circus state part to B - Ω

4.3.1 Circus state part to ISO Standard Z - Ω_1

The function Ω_1 translates the state part in a rewritten *Circus* program to a Z specification in ISO Standard Z. Because the state part of *Circus* is also written in ISO Standard Z, for most constructs they are just a direct map without changes. However, a rewritten *Circus* program still has the same structure as the original program—all state components and schemas are encapsulated within the processes—but the state and

```
R_{wrt} \begin{pmatrix} \mathbf{process} \ P \cong \mathbf{begin} \\ \mathbf{state} \ StPar == \begin{bmatrix} s_1 : T_1 ; \cdots s_n : T_n \mid p \end{bmatrix} \\ Pars == \begin{bmatrix} \cdots \end{bmatrix} \\ Op\_s_1 == \begin{bmatrix} \Xi StPar ; s_1! : T_1 \mid s_1! = s_1 \end{bmatrix} \\ \cdots \\ Op\_s_n == \begin{bmatrix} \Xi StPar ; s_n! : T_n \mid s_n! = s_n \end{bmatrix} \\ APars \cong B(APars) \\ \bullet \ A \\ \mathbf{end} \end{pmatrix}
= \begin{pmatrix} \mathbf{process} \ P \cong \mathbf{begin} \\ \mathbf{state} \ P\_StPar == \begin{bmatrix} P\_s_1 : T_1 ; \cdots P\_s_n : T_n \mid p \end{bmatrix} \\ P\_Pars == \begin{bmatrix} \cdots \end{bmatrix} \\ P\_Op\_s_1 == \begin{bmatrix} \Xi P\_StPar ; s_1! : T_1 \mid s_1! = P\_s_1 \end{bmatrix} \\ \cdots \\ P\_Op\_s_n == \begin{bmatrix} \Xi P\_StPar ; s_n! : T_n \mid s_n! = P\_s_n \end{bmatrix} \\ P\_APars \cong B(P\_APars) \\ \bullet \ R_{wrt}(A) \end{pmatrix}
```

Fig. 5: Renaming

$$\begin{split} R_{wrt}\left(\mathbf{Skip}\right) &= \mathbf{Skip} \\ R_{wrt}\left(\mathbf{Stop}\right) &= \mathbf{Stop} \\ R_{wrt}\left(\left(SExp\right)\right) &= \left(SExp\right) \\ R_{wrt}\left(\left(SExp\right)\right) &= \left(SExp\right) \\ R_{wrt}\left(\left(SExp\right)\right) &= \left(Op_s_i\right) \to \cdots \to \left(Op_s_j\right) \to \\ c!s_i!\dots!s_j \to R_{wrt}\left(A\right) \\ R_{wrt}\left(\left(g\right) \otimes_A A\right) &= R_{pre}(g) \to R_{pre}(A) \to \left(\left(g\right) \otimes_A R_{post}\left(A\right)\right) \\ R_{wrt}\left(A_1;A_2\right) &= R_{wrt}\left(A_1\right); R_{wrt}\left(A_2\right) \\ R_{wrt}\left(A_1 \sqcap A_2\right) &= R_{mrg}\left(R_{pre}(A_1), R_{pre}(A_2)\right) \to \\ \left(R_{post}\left(A_1\right) \sqcap R_{post}\left(A_2\right)\right) \\ R_{wrt}\left(A_1 \sqcap A_2\right) &= R_{mrg}\left(R_{pre}(A_1), R_{pre}(A_2)\right) \to \\ \left(R_{wrt}\left(A_1 \mid Rs_1 \mid cs \mid ns_2 \mid A_2\right) &= R_{mrg}\left(R_{pre}(A_1), R_{pre}(A_2)\right) \to \\ \left(R_{post}\left(A_1\right) \mid ns_1 \mid cs \mid ns_2 \mid R_{post}\left(A_2\right)\right) \\ R_{wrt}\left(A_1 \mid \mid ns_1 \mid ns_2 \mid \mid A_2\right) &= R_{mrg}\left(R_{pre}(A_1), R_{pre}(A_2)\right) \to \\ \left(R_{post}\left(A_1\right) \mid \mid \mid ns_1 \mid ns_2 \mid \mid R_{post}\left(A_2\right)\right) \\ R_{wrt}\left(A \setminus cs\right) &= R_{pre}\left(A\right) \to \left(R_{post}\left(A\right) \setminus cs\right) \\ R_{wrt}\left(A \setminus cs\right) &= R_{pre}\left(A\right) \to \left(R_{post}\left(A\right)\right) \text{ and } \left(R_{wrt}\left(X\right) = X\right) \\ R_{wrt}\left(A \mid R_{wrt}\left(R_{e}A\right)\right) &= R_{wrt}\left(R_{e}A_{e}A\right) \\ R_{wrt}\left(A \mid R_{e}A_{e}A\right) &= R_{wrt}\left(R_{e}A\right) \\ R_{wrt}\left(A \mid R_{e}A\right) &= R_{wrt}\left(A_{e}A\right) \\ R_{wrt}\left(A \mid R_{e}A\right) &= R_{w$$

Fig. 6: Action Rewriting

schemas in a ISO Standard Z specification are flat. Therefore, we need to merge all state components and schemas into one global and flat specification in ISO Standard Z.

 Ω_1 Rule 1 (States and Schemas Merge) If there are more than one explicitly defined process, their states and operations are merged in the resultant Z specification. Assume there are n explicitly defined processes, named P_1, P_2, \ldots, P_n , in a Circus specification. Their states and schemas are merged as shown in Figure 7. The state schema is a conjunction of state schemas from all processes, as well as the Init schema. All other schemas from each process will be translated to corresponding schemas with their own declaration and predicate. Additionally they shall keep state components

 Ω_1 (Rewritten *Circus* Program)

$$\begin{pmatrix} \operatorname{process} P_1 \cong \operatorname{begin} \\ \operatorname{state} P_1 \operatorname{St} Par == [P_1 \operatorname{..} s_1 : T_{11}; \cdots \\ P_1 \operatorname{..} s_{m_1} : T_{1m_1} \mid ps_1] \\ P_1 \operatorname{..} Init == [(P_1 \operatorname{..} St Par)' \mid pi_1] \\ P_1 \operatorname{..} Pars == [\operatorname{decl}_1 \mid p_1] \\ \bullet A \\ \operatorname{end} \end{pmatrix}$$

$$\cdots$$

$$\begin{pmatrix} \operatorname{process} P_n \cong \operatorname{begin} \\ \operatorname{state} P_n \operatorname{..} St Par == [P_n \operatorname{..} s_1 : T_{n1}; \cdots \\ P_n \operatorname{..} s_{m_n} : T_{mm_n} \mid ps_n] \\ P_n \operatorname{..} Init == [(P_n \operatorname{..} St Par)' \mid pi_n] \\ P_n \operatorname{..} Pars == [\operatorname{decl}_n \mid p_n] \\ \bullet A \\ \operatorname{end} \end{pmatrix}$$

$$= \begin{pmatrix} P_1 \operatorname{..} St Par == [P_1 \operatorname{..} s_1 : T_{11} ; \cdots P_1 \operatorname{..} s_{m_1} : T_{1m_1} \mid ps_1] \\ \cdots \\ P_n \operatorname{..} St Par == [P_n \operatorname{..} s_1 : T_{n1} ; \cdots P_n \operatorname{..} s_{m_n} : T_{nm_n} \mid ps_n] \\ \operatorname{State} == P_1 \operatorname{..} St Par \wedge \cdots \wedge P_n \operatorname{..} St Par \\ \operatorname{Init} == [(\operatorname{State})' \mid pi_1 \wedge \cdots \wedge pi_n] \\ \operatorname{P1} \operatorname{..} Pars == [P_1 \operatorname{..} Pars \operatorname{..} decl_1 ; \Xi P_2 \operatorname{..} St Par ; \cdots ; \Xi P_n \operatorname{..} St Par \mid P_1 \operatorname{..} Pars ..p_1] \\ \cdots \\ \operatorname{...} Pn \operatorname{..} Pars == [P_n \operatorname{..} Pars \operatorname{..} decl_n ; \Xi P_1 \operatorname{..} St Par ; \cdots ; \Xi P_{n-1} \operatorname{..} St Par \mid P_n \operatorname{..} Pars ..p_n] \end{pmatrix}$$

Fig. 7: Ω_1 Function

from other processes unchanged by including Ξ of all other state paragraphs into their declaration.

4.3.2 ISO Standard Z to ZRM - Ω_2

The function Ω_2 takes the constructs in ISO Standard Z as input and outputs the corresponding constructs in ZRM. It is only syntactical transformation. Only the transformation rules used in this paper are shown.

Ω_2 Rule 1 (Schema Decoration)

$$\Omega_2(S') = S'$$
 $\Omega_2((S)') = S'$

 Ω_2 Rule 2 (Horizontal Schema) In ISO standard Z, == is used for horizontal schema but $\widehat{=}$ in ZRM. Thus,

$$\Omega_2(==) = = =$$

4.3.3 ZRM to B machine - Ω_3

Our Ω_3 function, which translates from Z in ZRM to B machine, uses the implementation of ProZ [41] in ProB. Since ProB is the model checking tool for $CSP \parallel B$ specification, our solution is to translate Circus to Z in ZRM and CSP specifications, then supply them to ProB. Eventually, ProB translates Z to B by ProZ and model-checks it as $CSP \parallel B$ specification.

Furthermore, because only a considerable subset of Z is implemented in ProB and others [41] shown below are not supported, our solution is accordingly restricted.

- Generic definitions cannot be supported. Therefore, genericity in Circus is not supported.
- Reflexive-transitive closure construct is not supported.

4.4 Circus behaviour to CSP and Z - Φ

The function Φ transforms the behavioural part of a *Circus* specification to CSP and possibly Z.

 Φ Rule 1 (Types, Expressions and Operators) The translation rules for only a very small number of types and expressions are shown below.

- $\Phi(\mathbb{N})$ = Nat where Nat = $\{0..MAXINT\}$ and MAXINT is a constant declared in the beginning of CSP specification.
- $-\Phi(n..m) = \{n..m\}.$
- $\Phi(T_1 \times T_2) = \Phi(T_1).\Phi(T_2)$ if Cartesian product is used in the channel expression.
- $\Phi(T_1 \times T_2) = cross(\Phi(T_1), \Phi(T_2))$ if Cartesian product is used in other places.
- $\Phi(\text{seq }T) = fseq(\Phi(T))$ because Seq function in CSP_M is an infinite set of finite sequence, it cannot be the type of channel in CSP of ProB. Otherwise, it results in the infinite enumeration error. Our solution is to treat seq T as a partial function $\mathbb{Z} \twoheadrightarrow T$ but with extra restriction of maximum number of elements in its domain. Therefore, fseq function is defined in Figure 8. MAXINS denotes the maximum number of instances for model checking and it is put in the beginning of CSP specification like MAXINT.
 - * The cardinality of fseq(s) is equal to

$$\sum_{n=0}^{MAXINS} (card(s))^n$$

and if the size of s is 4 and MAXINS is 5, then the size of fseq(s) is 1365.

- * MAXINS is set by users but what is its optimum value highly depends on the programs to be checked and the computer that ProB runs on. On a powerful computer, it can be set to a higher value but still maintain reasonable model checking resources (memory, CPU and time) consumption.
- Abbreviation definition (AbbrDef == Expr) is linked to (nametype AbbrDef = $\Phi(Expr)$) in CSP.

Φ Rule 2 (Axiomatic Definition) An axiomatic definition

Fig. 8: fseq function

is translated to x = c, where c is an instance from the set $\{x \in T, p\}$ and shall be assigned manually before model checking. **Notes**: c shall match the value of constant x in Z.

- Φ Rule 3 (Channel Declaration) The link of the channel declaration in Circus to that in CSP is direct and straightforward.
- Φ (**channel** *chn_name*) = *channel chn_name*
- Φ (channel chn_name: T) = channel chn_name: Φ (T)
- Φ Rule 4 (Channel Set)

$$\Phi(\{ \} \}) = \{ || \}
\Phi(\{ \{c_1, c_2, \dots, c_n \} \}) = \{ \{c_1, c_2, \dots, c_n \} \}$$

 Φ Rule 5 (Channel Set Declaration)

$$\Phi(\mathbf{channelset} N == \{ | \}) = (N = \{ | \})$$

$$\Phi(\mathbf{channelset} N == \{ | c_1, c_2, \cdots, c_n | \}) = (N = \{ | c_1, c_2, \cdots, c_n | \})$$

4.4.1 Actions

The rules for a subset of Circus actions are shown below.

 Φ **Rule 6 (Basic Actions)** *The link of the basic actions in Circus to those in CSP is direct and straightforward.*

$$\Phi$$
 (Stop) = STOP
 Φ (Skip) = SKIP
 Φ (Chaos) = div

 Φ **Rule 7** (**Prefixing**) *The link of the prefixing in Circus to that in CSP is direct and straightforward.*

$$\begin{array}{ll} \boldsymbol{\Phi}\left(c \to A\right) &= c \to \boldsymbol{\Phi}\left(A\right) \\ \boldsymbol{\Phi}\left(c.e \to A\right) &= c.\boldsymbol{\Phi}\left(e\right) \to \boldsymbol{\Phi}\left(A\right) \\ \boldsymbol{\Phi}\left(c!e \to A\right) &= c!\boldsymbol{\Phi}\left(e\right) \to \boldsymbol{\Phi}\left(A\right) \\ \boldsymbol{\Phi}\left(c?x \to A\left(x\right)\right) &= c?x \to \boldsymbol{\Phi}\left(A\left(x\right)\right) \\ \boldsymbol{\Phi}\left(c?x : p \to A\left(x\right)\right) &= c?x : \left\{y \mid y < - \boldsymbol{\Phi}\left(T_c\right), \boldsymbol{\Phi}\left(p\right)\right\} \to \\ \boldsymbol{\Phi}\left(A\left(x\right)\right) &= c.$$

Φ Rule 8 (Schema Expression as Action) A schema expression as action (SExp) is linked to an external choice of the same name event SExp with input and output variables, and another event SExp f which precondition is the negation of precondition of SExp. Therefore, if the precondition of SExp holds, it engages SExp event; otherwise, it engages SExp f event and consequently diverges as div. Finally, these events are hidden from communication by adding both events to HIDE_CSPB. That makes it semantically equal to schema expression as action in Circus.

$$\Phi\left(\left(SExp\right)\right)$$

$$=\begin{cases} channel\ SExp\colon\Phi\left(T_{i}\right).\Phi\left(T_{o}\right)\\ channel\ SExp\:f\colon\Phi\left(T_{i}\right)\\ HIDE_CSPB=\{|SExp,SExp\:f|\}\\ (SExp!ins?outs\to SKIP\ \Box\ SExp\:f!ins\to\mathbf{div})\\ SExp\:f=\left[\Xi StPar\ ;ins?:T_{i}\mid\neg\mathbf{pre}\ SExp\right] \end{cases}$$

provided SExp is a schema in Z with input variables ins? and output variables outs!; SExp_f is an additional schema in Z; particularly, its predicate is the negation of the precondition of SExp.

Φ Rule 9 (Simplified Schema Expression as Action) If the precondition of SExp always holds such as state component retrieve schema expressions and assignments, the rule 8 is simplified because it is not possible to make its precondition be evaluated to false.

$$\begin{split} & \Phi \left(\left(SExp \right) \right) \\ & = \begin{cases} channel \ SExp: \Phi \left(T_i \right).\Phi \left(T_o \right) \\ HIDE_CSPB = \{ |SExp| \} \\ & \left\{ \left(SExp!ins?outs \rightarrow SKIP \right) \ if \left(SExp \right) \ as \ process \\ & \left(SExp!ins?outs \right) \ if \left(SExp \right) \ as \ communication \end{cases} \end{split}$$

 Φ Rule 10 (Miscellaneous Actions)

$$\Phi((g) \otimes A) = \Phi(g) \otimes \Phi(A)
\Phi(A_1; A_2) = \Phi(A_1); \Phi(A_2)
\Phi(A_1 \sqcap A_2) = \Phi(A_1) \sqcap \Phi(A_2)
\Phi(A \setminus cs) = \Phi(A) \setminus cs
\Phi(\mu X \bullet A(X)) = let X = \Phi(A(x)) within X$$

Φ Rule 11 (External Choice) External choice of actions in Circus is only resolved by external events of the process or termination. Internal events of the process, such as schema expression as action and assignment, would not resolve it. Thus we restrict the actions that can occur in external choice construct to AA.

$$\Phi(AA_1 \square AA_2) = \Phi(AA_1) \square \Phi(AA_2)$$

where AA can be one of actions below.

- Basic actions: Skip, Stop, or Chaos
- Prefixed actions: $c?x?...!e!\cdots \rightarrow A$

- Guarded commands: (g) &AA

Furthermore, provided both actions are guarded commands and their conditions $(g_1 \text{ and } g_2)$ are mutually exclusive, that is, $g_1 = \neg g_2$, then their guarded actions are not restricted.

$$\Phi\left(\left(g_{1}\right) \otimes A_{1} \Box \left(g_{2}\right) \otimes A_{2}\right)$$

$$= \Phi\left(\left(g_{1}\right) \otimes A_{1}\right) \Box \Phi\left(\left(g_{2}\right) \otimes A_{2}\right)$$

Φ Rule 12 (Iterated Operator)

$$\Phi\left(\mathbf{x}:T\bullet A\left(x\right)\right)=\mathbf{x}_{x:\Phi\left(T\right)}\bullet\Phi\left(A\left(x\right)\right)$$

$$\Phi\left(\Box x:T\bullet AA\left(x\right)\right)=\Box_{x:\Phi\left(T\right)}\bullet\Phi\left(AA\left(x\right)\right)$$

$$\Phi\left(\Box x:T\bullet A\left(x\right)\right)=\Box_{x:\Phi\left(T\right)}\bullet\Phi\left(A\left(x\right)\right)$$

 Φ Rule 13 (Parallel Composition and Interleaving) Variables in parallel composition are partitioned to ns_1 and ns_2 . Both actions can access the initial value of all variables from ns_1 and ns_2 , but they can only modify variables in their own partition ns_1 and ns_2 respectively. Our solution is to declare temporary variables tpv_1 and tpv_2 which are initialized to the initial value of all variables in scope pv_1 and pv_2 for A_1 and A_2 . Instead of updating pv_1 and pv_2 , we update tpv_1 and tpv_2 . Eventually, only variables in ns_1 and ns_2 are updated to the value of corresponding variables in tpv_1 and tpv_2 , and others are discarded.

$$\Phi(A_1 \llbracket ns_1 \mid cs \mid ns_2 \rrbracket A_2) =$$

$$\left(\Phi\left(\mathbf{var} tpv_1 \bullet \begin{pmatrix} tpv_1 := pv_1; \\ (A_1[tpv_1/pv_1]); \\ ns_1 := tpns_1 \end{pmatrix} \right) \right)$$

$$\parallel cs$$

$$\Phi\left(\mathbf{var} tpv_2 \bullet \begin{pmatrix} tpv_2 := pv_2; \\ (A_2[tpv_2/pv_2]); \\ ns_2 := tpns_2 \end{pmatrix} \right)$$

$$\Phi(A_1 || [ns_1 | ns_2] || A_2) =
\left(\Phi\left(\mathbf{var} tpv_1 \bullet \begin{pmatrix} tpv_1 := pv_1; \\ (A_1[tpv_1/pv_1]); \\ ns_1 := tpns_1 \end{pmatrix} \right)
||||
\Phi\left(\mathbf{var} tpv_2 \bullet \begin{pmatrix} tpv_2 := pv_2; \\ (A_2[tpv_2/pv_2]); \\ ns_2 := tpns_2 \end{pmatrix} \right) \right)$$

Φ Rule 14 (Parallel Composition and Interleaving (Disjoint Variables in Scope))

$$\Phi(A_1 [\![ns_1 \mid cs \mid ns_2]\!] A_2) = \Phi(A_1) [\![\Phi(A_2)]\!]$$

$$\Phi(A_1 [\![ns_1 \mid ns_2]\!] A_2) = \Phi(A_1) [\![\Phi(A_2)]\!]$$

provided

$$ns_1 = \alpha(A_1) = scpV(A_1)$$

 $ns_2 = \alpha(A_2) = scpV(A_2)$

where scpV is a function to get a set of all variables in scope in an action.

Φ Rule 15 (Variable Block) A variable block is linked to replicated internal choice in CSP which declares a set of local variables x and their initial value is arbitrary chosen. We use the memory model [35] (Definition 5) in CSP to maintain local variables. The linked process in CSP is put in parallel with replicated parallel of a set of memory cell processes. For each variable in x, there is a unique memory cell (MemCell process) that is distinguished by i.

$$\Phi\left(\mathbf{var}\,x:T\bullet A\right)=\bigcap_{x:\Phi(T)}\bullet\,F_{Mem}\left(\Phi\left(A\right),\left\{x\right\}\right)$$

Definition 3 (*MemCell* **Process**) A *MemCell* process defined below is the mechanism in CSP to store the value of a local variable. For each local variable, it shall have a *MemCell* process. Therefore, the process is distinguished by number *i* which is a unique number for each variable. *MemCell* process is initialized by set_i at first, and after that it will continuously provide update and retrieve of the variable by set_i and get_i channels respectively. Additionally, it is capable of terminating successfully through *end* event.

$$MemCell_i = set_i?x \rightarrow MCell_i(x)$$

 $MCell_i(x) = set_i?y \rightarrow MCell_i(y)$
 $\Box get_i!x \rightarrow MCell_i(x)$
 $\Box end \rightarrow SKIP$

Definition 4 (F_{Var} function) $F_{Var}(P, v)$ function makes every access to each local variable l from the set v in CSP process P by $get_i?l$, and every update to l by $set_i!l$. For example,

$$F_{Var}(c?x!y!z \rightarrow P, \{x, y, z\}) = get_i?y \rightarrow get_j?z \rightarrow c?x!y!z \rightarrow set_k!x \rightarrow F_{Var}(P, \{x, y, z\})$$

$$F_{Var}(c?x!y!z \rightarrow P, \{y\}) = get_i?y \rightarrow c?x!y!z \rightarrow F_{Var}(P, \{y\})$$

$$F_{Var}(P, \{y\})$$

$$F_{Var}(P, \{\}) = P$$

Definition 5 (F_{Mem}) The function F_{Mem} gives a memory model for CSP process P to store and retrieve local variables, which are shown in a set v with m elements: l_1, \dots, l_m .

$$F_{Mem}(P, v) = \begin{cases} (set_1! l_1 \to \cdots \to set_m! l_m \to SKIP; \\ F_{Var}(P, v); end \to SKIP) \\ \parallel \left(\left| \left| \left| \{MemCell_i \mid i \in \{1..m\}\} \right| \right. \right) \right| \lor vs \end{cases}$$

where $vs = \{|set_1, get_1, set_2, get_2, \cdots, set_m, get_m, end|\}$

 Φ Rule 16 (Action Renaming) The variable v_{old} is renamed to the v_{new} by the action renaming.

$$\Phi(A[v_{old} := v_{new}]) = \Phi(A[v_{new}/v_{old})$$

 Φ Rule 17 (Action Invocation) An action reference is the body of the action.

$$\Phi(A) = \Phi(B(A))$$
 provided $A \cong B(A)$

 Φ Rule 18 (Parametrised Action) A parametrised action invocation is the body of the parametrised action with the parameters x substituted by the expressions e.

$$\Phi(A(e)) = \Phi(B(A)[e/x])$$
 provided $A = x : T \bullet B(A)$

4.4.2 Processes

 Φ Rule 19 (Explicitly Defined Process) For an explicitly defined process, its main action is linked to a CSP process. Its state schema and operational schemas are linked to Z and finally B by the Ω function in Sect. 4.3.

$$\Phi \begin{pmatrix} \mathbf{process} \ P \cong \mathbf{begin} \\ \mathbf{state} \ StPar == [decl \mid pred] \\ Pars == [\cdots] \\ APars \cong B(APars) \\ \bullet A \\ \mathbf{end} \end{pmatrix} = (P = \Phi(A))$$

 Φ Rule 20 (Process Invocation) A process invocation is the process itself.

$$\Phi(P) = P$$

 Φ Rule 21 (Compound Process) For a compound process defined in terms of CSP operators, it is simply an operator expansion.

$$\Phi(P;Q) = \Phi(P); \Phi(Q)
\Phi(P \square Q) = \Phi(P) \square \Phi(Q)
\Phi(P \square Q) = \Phi(P) \square \Phi(Q)
\Phi(P \llbracket cs \rrbracket Q) = \Phi(P) \lVert \Phi(Q)
\Phi(P \lVert Q) = \Phi(P) \lVert \Phi(Q)
\Phi(P \lVert Q) = \Phi(P) \lVert \Phi(Q)
\Phi(P \backslash cs) = \Phi(P) \backslash cs$$

 Φ Rule 22 (Iterated Process) For a process defined in terms of an iterated operator in CSP, it is simply an operator expansion.

$$\Phi(\ ; x : T \bullet P(x)) = \ ;_{x : \Phi(T)} \bullet \Phi(P(x))$$

$$\Phi(\Box x : T \bullet P(x)) = \Box_{x : \Phi(T)} \bullet \Phi(P(x))$$

$$\Phi(\Box x : T \bullet P(x)) = \Box_{x : \Phi(T)} \bullet \Phi(P(x))$$

$$\Phi(\llbracket CS \rrbracket x : T \bullet P(x)) = \Big|\Big|_{CS_{x : \Phi(T)}} \bullet \Phi(P(x))$$

$$\Phi(\Big|\Big|\Big|_{x : T \bullet P(x)}) = \Big|\Big|\Big|_{x : \Phi(T)} \bullet \Phi(P(x))$$

Φ Rule 23 (Parametrised Process Invocation) For the parametrised process invocation, it is simply linked to its corresponding explicitly defined process after rewriting.

$$\Phi(PP(const)) = PP_const$$

$$\Phi(PP(x)) = (x == \Phi(x_1)) & PP_x_1$$

$$\Box (x == \Phi(x_2)) & PP_x_2$$

$$\cdots$$

$$\Box (x == \Phi(x_n)) & PP_x_n$$

where const denotes a constant.

Φ Rule 24 (Indexed Process Invocation) For the indexed process invocation, it is simply linked to its corresponding explicitly defined process after rewriting.

$$\Phi(IP[const]) = IP_const
\Phi(IP[x]) = (x == \Phi(x_1)) & IP_x_1
\Box(x == \Phi(x_2)) & IP_x_2
...
\Box(x == \Phi(x_n)) & IP_x_n$$

5 Case Study: Reactive Buffer

This section shows how the specification of a buffer and its implementation, a distributed reactive buffer, from the paper [12] can be linked to $CSP \parallel B$ by the links defined. Eventually, we model-check them by ProB. Particularly, the implementation is checked to be both a trace refinement and a failure refinement of the specification.

5.1 Buffer Specification

The specification of *BufferSpec* in *Circus* is shown in Figure 2.

5.1.1 Rewriting by R_{wrt}

According to our link definitions in Sect. 3, a *Circus* program such as *BufferSpec* is linked to a *CSP* \parallel *B* program by the function Υ .

Firstly, it is transformed by the R_{wrt} function to get a rewritten program RewrittenBufferSpec. We add two schemas named Op_buff and Op_size to retrieve state components buff and size respectively by the R_{wrt} Rule 5. Then we rename state components, schemas, actions and their references by prefixing $Buffer_$ by the R_{wrt} Rule 6. The only exception is the references to state components size and buff in the action. Finally we rewrite the main action of the process Buffer by the R_{wrt} Rule 7. After that, we get the rewritten program as shown in Figure 9.

```
section BufferSpec parents circus\_toolkit | maxbuff: \mathbb{N}_1 | channel input, output: \mathbb{N} | process Buffer \cong \mathbf{begin} | state Buffer\_State == [Buffer\_buff: seq \mathbb{N}; Buffer\_size: 0...maxbuff: | Buffer\_size = #Buffer\_buff \le maxbuff: | Buffer\_state = [(Buffer\_State)': | Buffer\_buff': = (() \land Buffer\_size': = 0)] | Buffer\_InputCmd == [\Delta Buffer\_State: x?: \mathbb{N}: | Buffer\_size < maxbuff: \land Buffer\_buff': = Buffer\_buff' < Buffer\_size': = Buffer\_size': = Buffer\_size': = Buffer\_size': = Buffer\_size': = Buffer\_size < 1] | Buffer\_OutputCmd == [\Delta Buffer\_State: | Buffer\_size: > 0 \land Buffer\_buff': = tailBuffer\_buff: \land Buffer\_size': = Buffer\_size < 1] | Buffer\_Op\_buff: = [\Xi Buffer\_State: | buff!: seq \mathbb{N}: | buff!: = Buffer\_buff: = Buffer\_buff: | Buffer\_size: = Buffer\_size: =
```

Fig. 9: Rewritten specification of Buffer

maxbuff = c

5.1.2 The Behavioural Part

Then the behavioural part of the rewritten program is translated by the Φ function (Φ (RewrittenBufferSpec)) to get a CSP specification illustrated in Figure 10. The rules of the Φ function that are applied sequentially are the channel declaration Φ Rule 3, the explicitly defined process Φ Rule 19, the type and expression Φ Rule 1, the sequential composition Φ Rule 10, the simplified schema expression as action Φ Rule 9, the basic action Φ Rule 3, the prefixing Φ Rule 7, the external choice Φ Rule 11, the guarded command Φ Rule 10, and the schema expression as action Φ Rule 8.

5.1.3 The State Part

Note that the behavioural translation of the schema expressions $Buffer_InputCmd$ and $Buffer_OutputCmd$ in Figure 10 produces two additional schemas— $Buffer_InputCmd_f$ and $Buffer_OutputCmd_f$ —according to the schema expression as action Φ Rule 8, and they are added in the rewritten program RewrittenBufferSpec before the translation of the state part to get RewrittenBufferSpec1.

Eventually the state part of *RewrittenBufferSpec1* is linked by Ω function to get a Z specification in Figure 11, where the Ω_3 function is applied in the later stage within ProB.

5.2 Distributed Reactive Buffer

The distributed cached-head ring buffer [12], an implementation of the buffer in Sect. 5.2, is a result of final development of refinement strategies. It is composed of the process *Controller* [12, Fig. 4], the process *RingCell* [12, Sect. 7.6], the indexed ring cell process *IRCell* [12, Sect. 7.6], and the process *Ring* [12, Sect. 7.6]. Finally the process *Buffer* [12, Sect. 7.4] is a parallel composition of the process *Ring* and

```
channel input, output: Nat
channel Buffer_Init
channel Buffer_Op_size : {0..maxbuff}
channel Buffer_Op_buff : Seq(Nat)
channel Buffer_InputCmd: Nat
channel Buffer_InputCmd_f: Nat
channel Buffer_OutputCmd
channel\ Buffer\_OutputCmd\_f
HIDE\_CSPB = \{ | Buffer\_Init, Buffer\_Op\_size, Buffer\_Op\_buff, \}
   Buffer_InputCmd, Buffer_InputCmd_f, Buffer_OutputCmd,
  Buffer_OutputCmd_f|}
Buffer = Buffer Init \rightarrow SKIP; let X =
        Buffer\_Op\_size?size \rightarrow Buffer\_Op\_buff?buff -
            (size < maxbuff) \& input?x \rightarrow
                 Buffer\_InputCmd!x \rightarrow SKIP
                                                              ;X
           (size > 0) \& output!(head(buff))
                 Buffer\_OutputCmd \rightarrow SKIP
                 Buffer\_OutputCmd\_f \rightarrow \mathbf{div}
 within X
```

Fig. 10: The Behavioural Part Translation

the process *Controller*. Obviously, this program shall have the definition of *maxbuff* and *maxring*, and the declaration of channels. In addition, we name this distributed cachedhead ring buffer as *DisBuffer*, and define additional abbreviation *RingIndex*. These definitions and declarations are shown in Figure 12. Note that the original *RingCell* has no initialisation schema and we explicitly add a schema named *Init*, that has the predicate *true*. The *Init* is the first event in the main action of the *RingCell*.

 Ω (RewrittenBufferSpec1) process $Buffer \cong \mathbf{begin}$ $Buffer_InputCmd_f == [\Xi Buffer_State; x? : \mathbb{N} \mid \neg \mathbf{pre} Buffer_InputCmd]$ $Buffer_OutputCmd_f == [\Xi Buffer_State \mid \neg pre Buffer_OutputCmd]$ section BufferSpec parents circus_toolkit $maxbuff: \mathbb{N}_1$ $Buffer_State == [Buffer_buff : seq \mathbb{N}; Buffer_size : 0 .. maxbuff | Buffer_size = \#Buffer_buff \le maxbuff]$ $Init == [(Buffer_State)' \mid Buffer_buff' = \langle \rangle \land Buffer_size' = 0]$ $\textit{Buffer_State} : \mathbb{N} \mid \textit{Buffer_state} : \mathbb{N} \mid \text{Buffer_state} : \mathbb$ $Buffer_size' = Buffer_size + 1$ $Buffer_InputCmd_f == [\Xi Buffer_State; x? : \mathbb{N} \mid \neg \mathbf{pre} Buffer_InputCmd]$ $Buffer_OutputCmd == [\Delta Buffer_State \mid Buffer_size > 0 \land Buffer_buff' = tailBuffer_buff \land Buffer_size' = Buffer_size - 1]$ $Buffer_OutputCmd_f == [\Xi Buffer_State \mid \neg \mathbf{pre} Buffer_OutputCmd]$ $Buffer_Op_buff == [\Xi Buffer_State; buff! : seq \mathbb{N} \mid buff! = Buffer_buff]$ $\textit{Buffer_Op_size} == \left[\, \Xi \textit{Buffer_State} \, ; \textit{size}! : 0 \, .. \, \textit{maxbuff} \mid \textit{size}! = \textit{Buffer_size} \, \right]$ [Ω_1 Rule 1] $maxbuff: \mathbb{N}_1$ $Buffer_State = [Buffer_buff : seq \mathbb{N}; Buffer_size : 0..maxbuff | Buffer_size = \#Buffer_buff < maxbuff]$ $Init = [Buffer_State' \mid Buffer_buff' = \langle \rangle \land Buffer_size' = 0]$ $Buffer_InputCmd \triangleq [\Delta Buffer_State; x?: \mathbb{N} \mid Buffer_size < maxbuff \land Buffer_buff' = Buffer_buff'\langle x? \rangle \land$ $Buffer_size' = Buffer_size + 1$ $Buffer_InputCmd_f = [\Xi Buffer_State; x? : \mathbb{N} \mid \neg \mathbf{pre}Buffer_InputCmd]$ $Buffer_OutputCmd \cong [\Delta Buffer_State \mid Buffer_size > 0 \land Buffer_buff' = tail\ Buffer_buff \land Buffer_size' = Buffer_size - 1]$ $\textit{Buffer_OutputCmd_f} \triangleq [\ \Xi \textit{Buffer_State}\ |\ \neg\textbf{pre}\ \textit{Buffer_OutputCmd}\]$ $Buffer_Op_buff \stackrel{\frown}{=} [\exists Buffer_State; buff! : seq \mathbb{N} \mid buff! = Buffer_buff]$ $Buffer_Op_size = [\Xi Buffer_State; size! : 0..maxbuff \mid size! = Buffer_size]$

```

Fig. 12: The preamble of *DisBufferSpec*

5.2.1 Rewriting by R_{wrt}

Firstly, the process IRCell is rewritten by the R_{wrt} Rule. Particularly, the set RingIndex shall be determined before rewriting the IRCell. We assume maxring is equal to 3 and thus

RingIndex = 1..3.

$$R_{wrt} \begin{pmatrix} \mathbf{process} \ IRCell \ \widehat{=} \\ (i:RingIndex \odot RingCell) \\ [rd.i,wrt.i := read,write] \end{pmatrix}$$

$$= \begin{pmatrix} R_{wrt} \begin{pmatrix} \mathbf{process} \ IRCell.1 \ \widehat{=} \\ (RingCell[rd,wrt := read.1,write.1]) \end{pmatrix} \\ R_{wrt} \begin{pmatrix} \mathbf{process} \ IRCell.2 \ \widehat{=} \\ (RingCell[rd,wrt := read.2,write.2]) \end{pmatrix} \\ R_{wrt} \begin{pmatrix} \mathbf{process} \ IRCell.3 \ \widehat{=} \\ (RingCell[rd,wrt := read.3,write.3]) \end{pmatrix}$$
[Renaming Operator R_{wrt} Rule 4]

[Ω_2 Rule 4.3.2]

The *IRCell* is expanded to three explicitly defined processes *IRCell*_1, *IRCell*_2, and *IRCell*_3. They are the same to the *RingCell* except that the channels *rd* and *wrt* in the *RingCell* are renamed.

Along with the *Controller* and *RingCell*, now we have five explicitly defined processes. According to the R_{wrt} rule in Figure 4, five additional schemas for the *Controller* and one for the *RingCell* are added within them to access each

```
process Controller 

begin
   Op\_size == [\Xi ControllerState; size!: 0..maxbuff]
     size! = size
   Op\_ringsize == [\Xi ControllerState; ringsize!: 0..maxring]
      ring size! = ring size
   Op\_cache == [\Xi ControllerState; cache! : \mathbb{N} \mid
      cache! = cache
   Op\_top == [\Xi ControllerState; top! : RingIndex | top! = top]
   Op\_bot == [\Xi ControllerState; bot! : RingIndex | bot! = bot]
end
process RingCell \stackrel{\frown}{=} begin
   Op_v = [\Xi CellState; v! : \mathbb{N} \mid v! = v]
process IRCell_{-}1 \stackrel{\frown}{=} begin
   Op_v == [\Xi CellState; v! : \mathbb{N} \mid v! = v]
end
process IRCell_3 = begin
   Op_{-}v == [\Xi CellState; v! : \mathbb{N} \mid v! = v]
end
```

Fig. 13: Additional Schemas for State Retrieve

state component. For *IRCell_1*, *IRCell_2*, and *IRCell_3*, they are similar. That is shown in Figure 13.

Then we rename state components, schemas, actions and their references of the *Contoller* and *RingCell* by prefixing *Controller*_ and *RingCell*_ respectively by the *R*_{wrt} Rule in Figure 5. The renamed *Controller* and *RingCell* are shown in Figure 14 and Figure 15 separately. It is also the similar case for *IRCell*_1, *IRCell*_2, and *IRCell*_3.

In the end, the main action of the *Controller* and the *RingCell* is rewritten by the R_{wrt} Rule in Figure 6. To begin with, the main action of the *Controller* is rewritten.

$$R_{wrt} \begin{pmatrix} \left(Controller_ControllerInit \right); \mu X \bullet \\ \left(Controller_InputController \\ \Box \\ Controller_OutputController \\ \end{pmatrix}; X \end{pmatrix}$$

$$= \begin{pmatrix} R_{wrt} \left(\left(Controller_ControllerInit \right) \right); \\ R_{wrt} \left(\mu X \bullet \begin{pmatrix} Controller_InputController \\ \Box \\ Controller_OutputController \\ \end{pmatrix}; X \right)$$
[Sequential Composition]

```
process Controller = begin

where

$$R_{wrt}\left(\left(size=0\right) & \left(Controller_CacheInput\right)\right)$$

$$= \begin{pmatrix} \left(Controller_OP_size\right) \rightarrow \left(size=0\right) & \\ R_{post}\left(\left(Controller_CacheInput\right)\right) \end{pmatrix}$$
[Guarded Command and Definition 1 of R_{pre} and R_{post}]
$$= \begin{pmatrix} \left(Controller_OP_size\right) \rightarrow \left(size=0\right) & \\ \left(Controller_CacheInput\right) \end{pmatrix}$$
[Schema Expression]

and

$$R_{wrt} \begin{pmatrix} (size > 0) \& write.top!x \rightarrow \\ (Controller_StoreInputController) \end{pmatrix}$$

$$= \begin{pmatrix} (Controller_OP_size) \rightarrow R_{pre} (write.top!x \rightarrow \cdots) \\ (size > 0) \& R_{post} (write.top!x \rightarrow (\cdots)) \end{pmatrix}$$
[Guarded Command and Definition 1 of R_{pre} and R_{post}]
$$= \begin{pmatrix} (Controller_OP_size) \rightarrow (Controller_OP_top) \\ \rightarrow (size > 0) \& \\ write.top!x \rightarrow (Controller_StoreInputController) \end{pmatrix}$$

[Prefixing and Schema Expression]

(11)

Analogous to the rewriting of *Controller_InputController*, *Controller_OutputController* is rewritten to

 $R_{wrt}(Controller_OutputController)$

$$= \begin{pmatrix} (Controller_Op_size) \rightarrow (Controller_Op_cache) \rightarrow \\ (size > 0) & output!(cache) \rightarrow (Controller_Op_size) \\ \rightarrow (Controller_Op_bot) \\ (size > 1) & read.bot?x \rightarrow \\ (Controller_StoreNewCacheController) \\ \Box \\ (size = 1) & (Controller_NoNewCache) \end{pmatrix}$$

$$(12)$$

In addition, it is the similar case for the rewriting of the main action of the *RingCell*, *IRCell*_1, *IRCell*_2 and *IRCell*_3 as well. Eventually, their main actions after rewriting are illustrated in Figure 16.

5.2.2 The Behavioural Part

The behavioural part of the rewritten program is translated by the Φ function to get a CSP specification.

process Controller = beginullet (Controller_ControllerInit); $\mu_X ullet$ (Controller_Op_size) \rightarrow $\Big($ Controller_Op_cache $\Big)$ $\stackrel{'}{\rightarrow}$ $(size < maxbuff) & input?x \rightarrow (Controller_Op_size)$ $\rightarrow (Controller_Op_top)$ $\rightarrow (size = 0) & (Controller_CacheInput)$ $\rightarrow (size > 0) & write.top!x \rightarrow (Controller_StoreInputController)$ $(size > 0) & output!(cache) \rightarrow (Controller_Op_size)$ $\rightarrow (Controller_Op_bot)$ $\rightarrow (size > 1) & read.bot?x \rightarrow$ $(Controller_StoreNewCacheController)$ \Box $(size = 1) & (Controller_NoNewCache)$ $\mathbf{process}\ \mathit{RingCell} \, \widehat{=} \, \mathbf{begin}$ • $\left(RingCell_Init \right)$; μ_X • $\left(RingCell_Op_v \right) \rightarrow$ process $IRCell_{-}1 \stackrel{\frown}{=} begin$ • (IRCell_1_Init); μ_X • (IRCell_1_Op_v) \rightarrow (read.1! $v \rightarrow$ Skip process $IRCell_2 = begin$ • $(IRCell_2_Init)$; μ_X • $(IRCell_2_Op_v)$ = end process $IRCell_3 \stackrel{\frown}{=} begin$ ullet (IRCell_3_Init); $\mu_X ullet$ (IRCell_3_Op_v) \to / read.3! $v \rightarrow \mathbf{Skip}$

Fig. 16: Rewrite of the main actions

First of all, the axiomatic definition of the *maxbuff* and the *maxring* is translated to

$$maxbuff = c$$
$$maxring = c - 1$$

by the Φ Rule 2, where c is a constant that is manually assigned before the model checking. For example, c = 3.

The abbreviation definition RingIndex is transformed to

nametype $RingIndex = \{1..maxring\}$

by the Φ Rule 1.

The channel declarations are transformed to

channel input, output: Nat

channel read, write: RingIndex.Nat

channel rd, wrt: Nat

channel rd_i, wrt_i : RingIndex.Nat

by the Φ Rule 3 and their expressions are transformed by the Φ Rule 1.

The behaviour of the *Controller* process is specified by its main action ma(Controller) in Figure 16.

$$\Phi$$
 (**process** Controller $\hat{=}$...) =

Controller = Φ (ma (Controller)) [Φ Rule 19]

Then its main action is translated. Here, the additional channel declarations and events added in HIDE_CSPB are omitted. In addition, when a schema expression is linked by Φ Rule 8, an additional schema is added in the state part. For example, $\Phi\left(\left(Controller_CacheInput\right)\right)$ generates the schema $Controller_CacheInput_f$. This is omitted here as well.

$$\Phi(ma(Controller))$$

$$=\Phi\left(\left(\textit{Controller_ControllerInit}\right)\right);\Phi\left(\mu X\bullet\ldots\right)$$

[Sequential Composition Φ Rule 10]

= $Controller_ControllerInit \rightarrow SKIP$; $\Phi(\mu X \bullet ...)$ [Schema Expression Φ Rule 9, Basic Actions Φ Rule 6]

$$= \cdots \text{let } X = \Phi \begin{pmatrix} \left(Controller_Op_size \right) \rightarrow \\ \left(Controller_Op_cache \right) \rightarrow \\ \cdots \end{pmatrix} \text{ within } X$$

[Recursion Φ Rule 10]

$$= \cdots \begin{pmatrix} Controller_Op_size?size \rightarrow \\ Controller_Op_cache?cache \rightarrow \\ \Phi(\cdots \square \cdots) \end{pmatrix}$$

[Schema Expression Φ Rule 9, Prefixing Φ Rule 7]

$$= \cdots \Phi\left(\left(\text{size} < \text{maxbuff}\right) \otimes \cdots\right) \Box \Phi\left(\left(\text{size} > 0\right) \otimes \cdots\right)$$
[External Choice Φ Rule 11]

= \cdots ((size < maxbuff) & Φ (input?x $\rightarrow \cdots$) $\square \cdots$)
[Guarded Command Φ Rule 10]

$$= \cdots \begin{pmatrix} input?x \rightarrow Controller_Op_size?size \rightarrow \\ Controller_Op_top?top \rightarrow \Phi(\cdots) \end{pmatrix} \square \cdots$$

[Prefixing Φ Rule 7, Schema Expression Φ Rule 9]

$$= \begin{pmatrix} \dots \\ \left((size == 0) & \Phi \left(\left(Controller_CacheInput \right) \right) \\ \square \\ \left(size > 0 \right) & write.top!x \rightarrow \\ \Phi \left(\left(Controller_StoreInputController \right) \right) \end{pmatrix}$$

[Guarded Command Φ Rule 10, Expression, Prefixing]

$$= \begin{pmatrix} \dots \\ \dots \\ Controller_CacheInput!x \to SKIP \\ \square \\ Controller_CacheInput_f!x \to \mathbf{div} \end{pmatrix}$$

$$\square \\ \dots \\ \begin{pmatrix} Controller_StoreInputController \to SKIP \\ \square \\ Controller_StoreInputController_f \to \mathbf{div} \end{pmatrix}$$

[Schema Expression Φ Rule 8]

$$= \cdots \Box \Phi ((size > 0) \& \cdots)$$
 [Similar to previous steps]

The behaviour of the RingCell process is given by its main action ma(RingCell) in Figure 16. Its translation is similar to that of the Controller process.

$$\Phi \left(ma \left(RingCell \right) \right) \\ = \cdots \\ = \begin{pmatrix} RingCell_Init \rightarrow SKIP ; \text{let } X = \\ \begin{pmatrix} RingCell_Op_v?v \rightarrow \\ rd!v \rightarrow SKIP \\ \\ wrt?x \rightarrow \\ \begin{pmatrix} RingCell_CellWrite!x \rightarrow SKIP \\ \\ \\ RingCell_CellWrite_f!x \rightarrow \mathbf{div} \end{pmatrix} \\ ; X \\ \text{within } X \\ [\Phi \text{ Rules}]$$

The behaviour of *IRCell_1*, *IRCell_2* and *IRCell_3* is their main actions as well. Only the translation of *IRCell_1* is displayed below.

$$\Phi$$
 (ma (IRCell_1))

 $= \cdots$

within X

$$= \begin{pmatrix} IRCell_1_Init \rightarrow SKIP; let X = \\ IRCell_1_Op_v?v \rightarrow \\ read.1!v \rightarrow SKIP \\ \square \\ write.1?x \rightarrow \\ IRCell_1_CellWrite!x \rightarrow SKIP \\ \square \\ IRCell_1_CellWrite_f!x \rightarrow \mathbf{div} \end{pmatrix}$$

[Φ Rules]

The *Ring* process is the interleaving of the indexed *IRCell* processes. It is link to

$$\Phi\left(Ring = \left(\left|\left|i:RingIndex \bullet IRCell[i]\right|\right)\right)$$
$$= \left(Ring = \left|\left|\left|i:RingIndex \bullet \Phi\left(IRCell[i]\right)\right|\right.\right)$$

[Iterated Interleave Φ Rule 22]

$$= \left(\textit{Ring} = \left| \left| \left| \right|_{i:\textit{RingIndex}} \bullet \left(\begin{array}{c} (i == 1) \ \& \ \textit{IRCell_1} \\ \square \ (i == 2) \ \& \ \textit{IRCell_2} \\ \square \ (i == 3) \ \& \ \textit{IRCell_3} \end{array} \right) \right)$$

[Indexed Process Invocation Φ Rule 24]

The *Buffer* process is translated to the *Buffer* process in CSP below.

$$\Phi\left(\begin{array}{c} \mathbf{process} \; \textit{Buffer} \; \widehat{=} \\ (\textit{Controller} \, [\![\{ | \textit{read}, \textit{write} \, |\!] \, |\!] \, \textit{Ring} \,) \setminus \{ | \textit{read}, \textit{write} \, |\!] \} \right) \\
= \left(\begin{array}{c} \textit{Buffer} \; = \\ \Phi\left(\begin{array}{c} \textit{Controller} & |\!| & \textit{Ring} \\ \{ | \textit{read}, \textit{write} \, |\!] \\ \end{array}\right) \setminus \{ | \textit{read}, \textit{write} \, |\!] \\
\text{[Process hide } \Phi \; \text{Rule 21, Channel Set } \Phi \; \text{Rule 4]} \\
= \left(\begin{array}{c} \textit{Buffer} \; = \\ \left(\begin{array}{c} \textit{Controller} & |\!| & \textit{Ring} \\ \{ | \textit{read}, \textit{write} \, |\!] \\ \end{array}\right) \setminus \{ | \textit{read}, \textit{write} \, |\!] \\
\text{[Parallel } \Phi \; \text{Rule 21, Process Invocation } \Phi \; \text{Rule 20]} \\$$

The *Buffer* process is the main process of the *DisBufferSpec* program. Thus when translated to CSP, the *MAIN* process is the *Buffer*.

$$MAIN = Buffer$$

5.2.3 The State Part

After the rewriting in Sect. 5.2.1 and the behaviour translation in Sect. 5.2.2, we have five explicitly defined processes: *Controller*, *RingCell*, *IRCell*_1, *IRCell*_2, and *IRCell*_3.

For the *Controller*, additional schemas are added by the schema expression as action Φ Rule 8 during the link of the behaviour to CSP.

- Controller_CacheInput_f
- Controller_StoreInputController_f
- Controller_NoNewCache_f
- Controller_StoreNewCacheController_f

For the *RingCell*, *IRCell_1*, *IRCell_2*, and *IRCell_3*, one additional schema is added for each process. They are *Ring Cell_CellWrite_f*, *IRCell_1_CellWrite_f*, *IRCell_2_CellWrite_f*, and *IRCell_3_CellWrite_f* separately.

The state part of the program is linked to a B machine by the Ω function that is composed of the Ω_1 , the Ω_2 and the Ω_3 . The Ω_3 is applied within ProB and so it is skipped here.

To begin with, the axiomatic definition and the abbreviation *RingIndex* are moved to the Z program directly.

Then the states and schemas from five explicitly defined processes are merged by the Ω_1 Rule 1. After that, the Ω_2 function is simply applied. Finally the state part is linked to a Z program.

The state schemas are merged as shown.

```
Controller_ControllerState \triangleq [

Controller_size : 0 . . maxbuff;

Controller_ringsize : 0 . . maxring;

Controller_cache : \mathbb{N};

Controller_top, Controller_bot : RingIndex |

Controller_ringsize mod maxring =

(Controller_top - Controller_bot) mod maxring \wedge

Controller_ringsize = max \{0, Controller\_size - 1\}

]

RingCell_CellState \triangleq [RingCell_v : \mathbb{N} | true]

IRCell_1_CellState \triangleq [RingCell_1_v : \mathbb{N} | true]

IRCell_2_CellState \triangleq [RingCell_2_v : \mathbb{N} | true]

IRCell_3_CellState \triangleq [RingCell_3_v : \mathbb{N} | true]

State \triangleq Controller_ControllerState \wedge

RingCell_CellState \wedge IRCell_1_CellState \wedge

IRCell_2_CellState \wedge IRCell_3_CellState
```

The initialisation schemas are merged.

$$Init \stackrel{\frown}{=} [State' \mid Controller_top' = 1 \land \\ Controller_bot' = 1 \land Controller_size' = 0 \land true]$$

$$(13)$$

All other schemas are merged as well. However for a schema from one process, it shall include the state schemas from other processes in its declaration part by Ξ notation to make sure no change is made to the state components from others. For example, the *Controller_Op_size* schema from the *Controller* becomes

```
Controller\_Op\_size \cong [\exists Controller\_ControllerState; \\ \exists RingCell\_CellState; \\ \exists RingCell\_1\_CellState; \\ \exists RingCell\_2\_CellState; \\ \exists RingCell\_3\_CellState; \\ size! : 0 ... maxbuff | size! = Controller\_size]
```

, Controller_CacheInput becomes

```
Controller_CacheInput \widehat{=} [\Delta Controller\_ControllerState; \\ \exists RingCell\_CellState; \\ \exists RingCell\_1\_CellState; \\ \exists RingCell\_2\_CellState; \\ \exists RingCell\_3\_CellState; \\ x?: \mathbb{N} \mid Controller\_size = 0 \land \\ Controller\_size' = 1 \land Controller\_cache' = x? \land \\ Controller\_bot' = Controller\_bot \land \\ Controller\_top' = Controller\_top]
```

, and Controller_CacheInput_f is transformed to

```
Controller_CacheInput_f \cong [
\Xi Controller_ControllerState;
\Xi RingCell_CellState; \Xi RingCell_1_CellState;
\Xi RingCell_2_CellState; \Xi RingCell_3_CellState;
x?: \mathbb{N} \mid \neg pre Controller_CacheInput]
```

The translation of other schemas are very similar and thus skipped.

5.3 Model Checking By ProB

Now we have got the final CSP program (Figure 10) and the Z program (Figure 11) for the buffer specification, and the CSP program (Sect. 5.2.2) and the Z program (Sect. 5.2.3) for the distributed buffer. Both of them can be model-checked by ProB. But before performing model checking, the value of the constants *MAXINT*, *MAXINS* and *maxbuff* shall be considered at first.

5.3.1 Maximum Instances *MAXINS* and **Maximum Size** of Buffer *maxbuff*

For the buffer specification, the type of buffer is $seq \mathbb{N}$. When linked to $CSP \parallel B$, we use fseq (Figure 8) that introduces the bound constant MAXINS. Finally the size of the set of finite sequences by fseq highly relies on the value of MAXINS as well as the data set s. The defined fseq computes the result

relied on several intermediate functions (squash, pfun, rel and cross) which are defined in the functional language as well. The consumption of resources during resolution is still high. If the size of s is big and MAXINT is large, ProB will take longer time to compute all possible finite sequences. For an instance, on the system having 2GB RAM and 2.5 GHz CPU, and running Ubuntu 12.04, it takes approximately thirty minutes for ProB to load the CSP program when the size of s is 4 (MAXINT is set to 3) and MAXINS is 5. However if the size of s is reduced to 2, we can increase MAXINS to 9 to make ProB load the CSP program still in a shorter time. Alternatively, instead of using the functional language to resolve fseq, we can compute all finite sequences in advance by another language, let's say Perl, then include them explicitly into a set and replace fseq in CSP programs by this set. For example, if s is $\{0,1\}$ and MAXINT is 2, then we can get this set as $\{\langle \rangle, \langle 0 \rangle, \langle 1 \rangle, \langle 0, 0 \rangle, \langle 0, 1 \rangle, \langle 1, 0 \rangle, \langle 1, 1 \rangle\}$. By this way, it can reduce the program load time tremendously. But the loss of flexibility is a side effect because we have to compute this set in advance and externally (out of ProB).

For the buffer specification the value of *maxbuff* shall be less than or equal to *MAXINS*.

5.3.2 Data Independence and MAXINT

The type of data (T) in both the buffer specification and the buffer implementation is N. According to the definition of data independence [28, Sect. 2.7] and [43, Sect. 15.3.2], both the linked buffer programs in $CSP \parallel B$ are data-independent because they input values of \mathbb{N} along their *input* channels, store them in a sequence or a set of ring cells, and then output values in order along their output channels without any computations. And they do not perform any explicit and implicit equality tests over T, therefore they satisfy **NoEqT** [28, 42]. In addition, the Buffer process in the linked buffer specification (Figure 10) satisfies Norm [28, 42]. According to Theorem 17.2 [42], the threshold of the size of Tsuch that the implementation is a refinement of the specification in terms of traces, failures and failures-divergences is 2. There is a similar conclusion in the book [42, p.397] that the threshold of an N-bounded buffer for any N is 2. So for the refinement check, we can set MAXINT to 1 as there are two elements $\{0,1\}$ and set *maxbuff* to 3. Actually, we also checked the refinement when MAXINT is increased to 3.

5.3.3 Model Checking of Buffer Specification

When model-checking this case by ProB, we notice ProB kernel treats $seq\ T$ as set(couple(integer,T)) in Z and B. But it fails to match the sequence type in CSP. Therefore, it generates an incompatible type error. We change the implementation of predicate type_ok and is_csp_set_type

Table 1: Model Checking Performance Comparison (Buffer Specification)

MAXINT	MAXINS	maxbuff	Time (ms)	Memory (MB)
3	3	1	122	38
3	3	2	538	38
3	3	3	2,152	39
3	4	4	28,022	40
3	5	5	443,306	78
1	9	9	16.802	68

in specfile.pl of ProB kernel source code to make set(couple(integer, T)) match the sequence type in CSP.

Additionally, div, the most divergent process, is not available in CSP_M as well as ProB. We define a process DIV as $div \rightarrow STOP$, where div is a special event, in CSP for **div**. Though DIV is not a divergent process, we can check deadlock of combination of CSP and Z specifications to achieve divergence checking. We use the deadlock checking to find this kind of divergence because it is a more direct checking in ProB. In case that a deadlock is found, we check the counterexample to see if the last event is div or not. If the last event is div, it means the original Circus specification can lead to divergence. Alternatively, LTL formula checking can be used to check deadlock as well. For example, the LTL formula (not F e(div)), which denotes the statement that finally div event is enabled, is not true. When it comes to this case, if we remove guarded conditions in Input or Output action in Figure 2, the specification diverges because the precondition of *InputCmd* and *OutputCmd* may not hold. In the final CSP specification in Figure 10, the corresponding boolean guard is removed as well. Using ProB, we can easily find the deadlock and the last event is div, therefore it finds divergence.

Deadlock and Invariant Violation Checking Finally, we can model-check the combination of CSP and Z specifications and there is no deadlock found. A comparison of the model checking performance for different configuration of constants is shown in Table 1. This experiment was undertaken on ProB Linux version, which is modified based on ProB 1.5.0-Beta, on Ubuntu.

Deadlock and Divergence Checking by CSP Assertions ProB is capable of deadlock and divergence checking through CSP assertions as well. By adding the following three asserts to the CSP program (Figure 10), we checked the deadlock free and divergence free of the *Buffer* process with the combination of constants in Table 1 successfully.

assert Buffer :[deadlock [F]]
assert Buffer :[deadlock [FD]]
assert Buffer :[livelock free]

5.3.4 Model Checking of Distributed Reactive Buffer

One issue we found is about the well-definedness of the modulo operation in Z when it is translated to the counterpart in B. In Z, the modulo operation is defined on the integer dividend and the non-zero integer divisor [47]. However it is defined on the natural number dividend and the nonzero natural number divisor in B machine. Therefore, when model-checking this case by ProB that translates the modulo to the modulo operation in B, it triggers an error about the well-definedness of the modulo because the dividend of the modulo in Z is possibly less than 0. Thus, we modified the implementation of the modulo operation in ProB to use the modulo operation *mod* in SICStus Prolog. Because the modulo operation in Z uses truncation towards minus infinity [47] and in Prolog it is the integer remainder after floored division [2], they use the same definition of modulo—floored division [29]. Hence, the well-definedness of mod in Z is retained.

In addition, ProB uses the build-in command time in Tcl to measure the elapsed time for the model checking task. It can count up to 4,294,967,295 microseconds, approximately 72 minutes, for a task in a 32-bit machine, otherwise it will cause the overflow. For the model checking of this case with the *maxbuff* larger than 3, it requires longer time and causes the overflow. Therefore, the output result about the time is not useful. We record the timestamp before the task execution and the timestamp after the completion of the task by clock milliseconds in Tcl, then calculate the difference between two timestamps. This is the model checking time.

Deadlock and Invariant Violation Checking There is no deadlock or divergence found. A comparison of the model checking performance is shown in Table 2. Note that due to the state space exploration and resource limitation, we are not able to model check this case if maxbuff is larger than 3 and MAXINT is 3 because ProB runs out of memory on Linux with 3 GB memory. We can set the MAXINT to 1 to reduce the state space. The result is shown in the third row. Further methods like more specific initialisation can be used to tremendously decrease the size of the state space. For an instance, if we substitute (13) by the initialisation schema (14), the model checking result is displayed in the fourth row.

$$Init \triangleq [State' \mid Controller_top' = 1 \land Controller_bot' = 1$$

$$\land Controller_size' = 0 \land Controller_ringsize' = 0$$

$$\land Controller_cache' = 0 \land RingCell_v' = 0$$

$$\land IRCell_1_v' = 0 \land IRCell_2_v' = 0$$

$$\land IRCell_3_v' = 0 \land IRCell_4_v' = 0]$$

$$(14)$$

Deadlock and Divergence Checking by CSP Assertions By adding the following three asserts to the CSP program (Sect.

Table 2: Model Checking Performance Comparison (Buffer Implementation)

MAXINT	maxbuff	maxring	Time (ms)	Memory (MB)
3	2	1	38,039	53
3	3	2	2,582,944	837
1	4	3	951,593	913
1	4	3	236,532	318 ^a

^a This row is the result with substituted initialisation schema.

5.2.2), we checked the deadlock free and divergence free of the *Buffer* process with the combination of constants in Table 2 successfully.

assert Buffer :[deadlock [F]]
assert Buffer :[deadlock [FD]]
assert Buffer :[livelock free]

5.3.5 Refinement Checking

In addition, ProB can check if an implementation in $CSP \parallel B$ is a trace refinement of a specification in $CSP \parallel B \parallel 30 \parallel$. When checking the trace refinement, an issue we got in ProB for our case, after inspecting source code, is that ProB refinement checker compares the traces of both the specification and the implementation according to their transitions in the same state space. That works for the refinement of two processes in the same CSP program for the CSP model, or the refinement of two processes in the same CSP program for the $CSP \parallel B$ model. But for our case, the specification and the implementation have the different Z programs and it is impossible to put their CSP programs into one CSP file. Thus we modified the refinement_checker.pl of ProB to search the traces by the transitions from their own separate state space. After model-checking the buffer specification, we save its state space for later refinement check to a file. Then we load the buffer implementation to ProB, and select "trace refinement check" function, open the saved state space file for the specification. Finally ProB will show the result: the implementation is a trace refinement of the specification; or if not a trace refinement, a counter example is provided.

We checked the trace refinement between the buffer specification and the buffer implementation, and finally got the result the distributed reactive buffer is a trace refinement of the buffer specification for *MAXINT* and *maxbuff* equal to 3 and 3 separately. Furthermore, ProB has an option to check failures. We checked the failure refinement between the specification and the implementation as well, and finally found the distributed reactive buffer is also a failure refinement of the buffer specification with the same constants. The refinement checking performance is shown in Table 3. According to Sect. 5.3.2, we can conclude the buffer implementation is a failure refinement of the buffer specification.

Table 3: Refinement Check Performance

Model	MAXINT	maxbuff	maxring	Time (ms)
Traces	1	3	2	109,180
Failures	1	3	2	122,440
Traces	3	3	2	342,440
Failures	3	3	2	355,320

However, if *maxbuff* between the specification and the implementation is not equal, ProB gives an error with a counterexample provided.

6 Conclusions and Future Work

Related work Model checking and animation are regarded as a very important tool support for the application of formalisms in both academia and industry. There are three existing solutions for implementing or model-checking Circus programs. The first solution is JCircus [21, 36, 40] which translates a concrete Circus program to a Java program with JCSP [48]. After that, linking Circus to CSP [7] aims to translate Circus to CSP_M then use FDR2 [1] to model-check CSP specification. The last one is mapping *Circus* processes and refinement to CSP processes and refinement [31,39] that transforms stateful Circus to stateless Circus first by introducing the memory model, and then converts stateless Circus to CSP. The first is not a model checking solution but implementation instead, and it is restricted to executable Circus programs because Java is an imperative programming language and not a high-level specification language. Therefore, before supplying the *Circus* program to *JCircus*, it has to be refined to a concrete program. For the second solution, it is not clear how to connect the data part to the behavioural part of a Circus program. The third solution transforms both state and behavioural parts to CSP specification, which means all states are maintained in CSP. It is restricted to divergence-free Circus. Furthermore, it is not convenient and capable in CSP to maintain very complex states, and rather difficult to understand the final CSP specification if it contains a lot of state operations.

Our work Comparatively, our work links Circus to CSP \parallel B to express the behavioural and state parts, which maintains the high-level abstraction. And using B to specify the state part is more straightforward and easier than using CSP. The capability of linking most of constructs in Circus to CSP \parallel B is another advantage because Circus itself consists of a large amount of syntactic constructs. Additionally, the capabilities of deadlock checking, LTL formula checking, refinement checking, automatic and manual animations are very important as well. Last but not least, we achieve the divergence checking of original Circus program by deadlock checking of CSP \parallel B.

However, this work has some limitations as well. *Generics* in *Circus* are not supported; for $CSP \parallel B$, its state is composed of the state from B and the state of the process from CSP, and is expressed as a pair [9], thus its state space is more complex for exploration; limited actions can occur in both sides of external choice (Φ Rule 11) due to the semantics of external choice [37]; the rule of parallel composition of actions (Φ Rule 13) achieves semantical equality but is difficult to implement because we need to keep a copy of temporary variables in CSP for both state variables in B and local variables, which makes the state maintained in CSP temporarily before merge and is against our strategy that state and behaviour are separated in B and CSP; how to trace $CSP \parallel B$ back to Circus is an issue.

Future work By now, we have defined the translation rules for a large subset of constructs in Circus, given the soundness, and developed a simple translator which can deal with very limited rules. We will continue to study a more complicated case, extend the translator to support approximately all rules defined. Most significantly, we need to minimize the limitations. For instance, we may modify the operational semantics of $CSP \parallel B$ in ProB to make external choice resolved only by external events and termination but not communication between CSP and B, which makes all actions can occur in external choice. In addition, for link of axiomatic definition to CSP (Φ Rule 2), we will modify the implementation of ProB to make it instantiated to the same value as in Z.

Acknowledgements We thank Leo Freitas and Andrew Butterfield for discussions about the link approach, CZT as well as the insights of difficulties.
