ABSTRACT

Objective: To characterize health seeking behavior (HSB) and determine its predictors amongst children in Malawi in 2016.

Methods: We used the 2016 Malawi Integrated Household Survey dataset. The outcome of interest was HSB, defined as seeking care at a health facility amongst people who reported one or more of a list of possible symptoms given on the questionnaire in the past two weeks. We fitted a multivariate logistic regression model of HSB using a forward step-wise selection method, with age, sex and symptoms entered as a priori variables.

Results: Of 5350 children, 1666 (32%) had symptoms in the past two weeks. Of the 1666, 1008 (61%) sought care at health facility. The children aged 5 to 14 years were less likely to be taken to health facilities for healthcare than those aged 0 to 4 years. Having fever vs. not having fever and having a skin problem vs. not having skin problem were associated with increased likelihood of HSB. Having a headache vs. not having a headache was associated with lower likelihood of accessing care at health facilities (AOR= 0.50, 95%CI: 0.26-0.96, P=0.04). Children from urban areas were more likely to be taken to health facilities for healthcare (AOR= 1.81, 95%CI: 1.17-2.85, P=0.008), as were children from households with a higher socioeconomic position (AOR= 1.96, 95%CI: 1.13-3.40, P=0.02).

Conclusion: There is a need to understand and address individual, socioeconomic and geographical barriers to health seeking to increase access and use of healthcare and fast-track progress towards Universal Health Coverage.

Key words: Malawi; Healthcare Seeking Behaviour; Determinants of Health

INTRODUCTION

Health seeking behaviour (HSB) refers to action taken by individuals when ill in order to find appropriate remedies [1] [2]. HSB is a good predictor of health service utilisation at community level and can be affected by educational levels, economic factors, cultural beliefs and practices, socio-demographic factors, knowledge about the facilities, gender issues, and the health care system itself [3] [4]. HSB is preceded by a decision-making process governed by individual or household behaviour, community norms, and expectations, as well as provider-related characteristics [2]. Studies conducted in Malawi and Uganda have identified disparities in HSB by geographic location with certain communities having more access to health services than others [3] [5] [6].

Studies assessing the barriers to HSB for carers of children in Ethiopia, Kenya, Malawi, Tanzania and South Africa have found significant impacts of socioeconomic status, male sex, lack of awareness of the need for primary care, cultural beliefs, peer influences, distance and cost [7] [8] [9] [10] [11]. The probability of HSB varies by age, sex, location and socio-economic position in settings in sub-Saharan Africa. Specifically, HSB has been higher in the rural population and those with a higher socio-economic position among other factors [7] [12].

Most of the studies conducted on HSB of children in Malawi have considered HSB in specific districts or urban or rural settings and analyzed one illness at a time. There is a dearth of knowledge on factors associated with more generalized HSB in Malawi among children. Therefore, we aimed to characterize healthcare seeking behaviour and determine its predictors amongst carers of children in Malawi in 2016. We specifically estimated the probability of healthcare seeking given the presence of specific symptoms and determined the factors associated with HSB among children from households interviewed during the 2016 integrated household survey (IHS) in Malawi.

METHODS

Study Design and Introduction to Integrated Household Survey

We examine the factors associated with HSB using a cross-section sub-sample of children in the Malawi IHS 2016 [13]. The IHS are implemented by the Government of Malawi through the National Statistical Office (NSO) as part of the World Bank Living Standards Measurement Study – Integrated Surveys on Agriculture (LSMS-ISA) initiative [13]. The Integrated Household Survey is one of the primary instruments implemented by the Government of Malawi through the National Statistical Office (NSO) roughly every 5 years to monitor and evaluate the changing conditions of Malawian households. The IHS data have, among other insights, provided benchmark poverty and vulnerability indicators to foster evidence-based policy formulation and monitor the progress of meeting the Millennium Development Goals (MDGs), the

goals listed as part of the Malawi Growth and Development Strategy (MGDS) and now the Sustainable Development Goals (SDGs) [14].

The training of enumerators was conducted from 22 February 2016 to 25 March 2016 [14]. The NSO trained 110 research assistants. Of these, 18 were earmarked for team leaders and 92 were earmarked for data collection [14]. Of the 92 enumerators, 20 were kept on reserve to replace those who would leave in the process of data collection. There were 18 mobile teams each covering approximately two districts. Each team had a team leader, 4 enumerators, and a driver. Data collection started on the 15th of April 2016 and finished on 30 April 2017 [14].

The IHS has a number of modules that were relevant to this study. The household roster contained demographic data on all the members of the interviewed households. The health section contained information on symptoms in the past two weeks and any resulting health care seeking behaviour. Furthermore, both non-chronic and chronic conditions were captured in this section. Households were asked to provide a maximum of two symptoms experienced by each household member in the preceding two weeks. Although the pre-populated list had thirty symptoms included in the survey questionnaire, by design of the questionnaire only two symptoms were allowed to be reported by the household member.

Sampling Procedure

The IHS applied a two-stage sampling procedure and used a nationally representative sample. The sampling frame was based on the 2008 Malawi Population and Housing Census [15]. The primary sampling units (PSUs) were the census enumerations areas (EAs) defined for the 2008 Malawi Population and Housing Census. The EA is the smallest operational area established for the census with well-defined boundaries and has an average of about 235 household [15].

Data Management

From the household roster of the IHS questionnaire we obtained age, sex (male/female), residence (rural/urban), district, region of residence (North/Central/Southern), carer level of education (none/primary/tertiary), and sampling weights. From the health section of the IHS questionnaire we extracted information on whether the child experienced any symptoms in the past two weeks, name of symptom, HSB (visiting or not visiting a health facility). The symptoms were mapped as shown in Box 1. During mapping, we grouped similar symptoms together as follows: fever or malaria (if they had fever or malaria), diarrhoea or vomiting (if they had diarrhea or were vomiting), sore throat (if they had sore throat and ear/nose/throat problems) and respiratory tract infections (if they had upper respiratory (sinuses), lower respiratory (chest, lungs), and flu) and other, including fainting, feeling pain when passing urine, mental disorder, tuberculosis, sexually transmitted infections, unspecified long-term illnesses, and

other illnesses.

HSB was equal to 1 if the person sought healthcare from private, government or faith-based health facilities as well as village health clinics and local pharmacies while HSB was equal to 0 if people did not access healthcare, or sought care through alternative providers, for example traditional or faith healers. In this analysis we included only persons aged up to 14 years.

We computed the wealth quintile, proxy for wealth status, using factor analysis using an algorithm outlined by Measure Demographic and Health Surveys [16]. Wealth quintile is an asset-based measure employed in locations where incomes are difficult to measure [17]. Assets including livestock and birds (goats, sheep, cattle, donkeys, pigs and chicken), utilities (electricity and running water), type of dwelling and other properties such as radio sets were used to construct our wealth quintiles [17]. In this study, we used the following to compute the wealth quintile: (a) Floor material (sand, smoothed mud, smooth cement, tile, other), (b) cooking fuel (firewood, crop residue, other, paraffin, electricity, charcoal), (c) water supply (personal open unprotected well, communal open unprotected well, river, spring, lake, reservoir, other, piped into dwelling, piped outside dwelling, communal standpipe, personal hand-pump, communal hand-pump, protected spring), (d) toilet facility (no toilet facility, other, flush toilet, VIP latrine, traditional latrine with roof, latrine without roof), and (e) ownership of assets (bed, chair, table, radio, television, bicycle, motorcycle, and car or bus). We generated the tertiles and ranked them from the lowest to the highest in line with the Measure Demographic and Health Surveys [16]. The wealth index tertiles were derived from the quintiles in which the bottom two were combined and the upper two categories of the quintiles were combined in order to come up with the wealth index tertiles.

Box 1: Showing mapping of thirty symptoms captured into fifteen symptoms using the 2016 Malawi Integrated Household Survey

Symptom from survey	Mapped to the variable
Fever and Malaria	Fever/Malaria
Diarrhoea and Vomiting	Vomiting/Diarrhoea
Stomach Ache	Stomach Ache
Sore Throat and Ear/Nose/Throat	Sore Throat
Upper Respiratory (Sinuses), Lower Respiratory (chest, lungs), and Flu	Respiratory Infection
Headache	Headache

Skin Problem	Skin Problem
Dental Problem	Dental Problem
Eye Problem	Eye Problem
Backache	Backache
Burn, Fracture and Wound	Injuries
Fainting, Pain when Passing Urine, Mental Disorder, Tuberculosis, Unspecified Long-term Illnesses, and Other Illnesses	Other

Data Analysis

We calculated frequency, proportions, odds ratios (OR) and their associated 95% confidence intervals (95%CI). Data were analysed with STATA 15.1 (Stata Corp., Texas, USA). We weighted all household level analyses as detailed above, and performed both bivariate and multivariate analyses of the effect of socio-demographic factors of the carer and symptoms on the binary endpoint of HSB. We fitted a multilevel mixed-effects logistic regression model of HSB using a forward step-wise selection method. Child's age, sex and reported symptoms were entered as a priori variables in the multivariate model. To determine whether a factor was included in the model, the likelihood ratio test (LRT) was used. We set the level of statistical significance at $P < 0.05$.

Ethical Considerations

We obtained permission to use this data from the World Bank to access the Malawi IHS datasets from <https://microdata.worldbank.org/index.php/catalog/2939>. Furthermore, this study was approved by the College of Medicine Research Committee (COMREC) in Blantyre, Malawi (protocol #: P.10/19/2820). As this study used secondary anonymised data, the issue of individual informed consent did not apply.

RESULTS

Characteristics of children from interviewed households in Malawi

The characteristics of the children included in the study are shown in Table 1. A total of 5350 children were evaluated in the 2016 IHS survey round. 52% were girls, and 83% of the children were from rural areas. The majority were aged between 5 and 14 years rather than under 5 years (Table 1). The overall median age of the children was 7 years (interquartile range (IQR):3-11).

The largest number of children were from the southern region while the least number were from the northern region (Table 1). 45% of children came from households of low wealth index; 31% from households of high wealth index (31%). There were fewer children from households with a household

head of at least 60 years than children from houses with household heads of 35 to 59 years of age (Table 1). A total of 4951 (94% of 5350) children were from households where the head had no formal education.

Symptoms within the past two weeks prior to survey amongst children in Malawi

As Table 1 shows, 32% of the 5350 children had symptoms in the past two weeks. A higher proportion of children from rural than urban areas reported symptoms. There were regional variations in the proportions of children with symptoms; with children from the southern region being less likely to be ill compared to those from either the central or northern region ($P=0.0001$). A significantly higher proportion of children under 5 years had symptoms than older children ($P<0.001$). A lower proportion of children from rich households had symptoms than those from the poor households ($P=0.001$). The proportion of boys and girls who had symptoms in the past fourteen days was similar.

Amongst the 1666 children with symptoms within the past two weeks, the most common symptoms reported were fever (48% of 1666), followed by respiratory tract infections (15% of 1666) and then headache (9% of 1666) as shown in Table 2a. The least common illnesses reported were dental problems (0.4% of 1666), eye problems (1% of 1666) and skin problems (4% of 1666). No child reported back pain in the two weeks prior to the survey. A total of 231(4%) of the 5350 children had chronic conditions. Of these, 127 (58%) had been ill within the previous two weeks. The numbers and percentages of children with chronic conditions are shown in Table 2b. The most common chronic condition was asthma (6%) while the rarest was arthritis (0.1%).

Places where children were taken for healthcare

The places where the children were taken for healthcare are shown in Table 3. Of the 1666 children reporting symptoms, 1573 (94%) were taken for health care while 93 (6%) were not due to lack of money or illness being perceived as not serious. Of those that were taken for healthcare, 1008 (64% of 1573) were taken to a healthcare facility; 756 (45%) sought care from government health facilities and 146 (9%) from private clinics. Amongst the 659 children that were not taken for care at a health facility, 408 (62%) bought medicines from grocery stores and 105 (16%) used the medicines that they had in stock at their homes.

There were 127 children with chronic conditions. Of these, 90 (70%) were taken to health facilities for health care while 37 (30%) that did not seek health care from hospitals. Amongst those who did not seek care from hospitals, 22 (59%) bought drugs from the grocery stores while the remainder used herbal medicine (9%) or did nothing (32%).

Factors associated with healthcare seeking behaviour for children in Malawi

Bivariate Analysis of Health Seeking Behaviour

Overall, 60% of the children were taken for health care in the health facilities (Table 1). The proportion of children that received health care from health facilities varied by region ($P = 0.02$) with the northern region having the highest proportion (72% of 185) while the fewest were observed in the central region (57% of 816). HSB was higher in urban than rural areas (Table 1). There was similar HSB for boys and girls in Malawi in 2016. Children aged 0 to 4 years had a significantly higher HSB than those aged 5 to 14 years ($P = 0.001$). The children from households of higher wealth status had higher HSB than those from households of lower wealth status (68% of 539 vs. 55% of 778 respectively). The distribution of children taken for health care at facility was similar by age of the household head (Table 1).

Healthcare seeking behaviour also varied by type of symptom of the child as shown in Table 2. The highest health seeking behaviour was observed amongst children with skin problems (78%), followed by those with fever (71%) and those with eye problems (67%).

Multivariate Analysis of Health Seeking Behaviour

The factors associated with health seeking behaviour are shown in Table 4. Health seeking behaviour varied by age of child, residence, socio-economic position, comorbidity with chronic conditions, and reported symptom. After adjusting for sex and child's symptom, the children aged 5 to 14 years were less likely to be taken for healthcare at health facilities than the children aged 0 to 4 years (AOR=0.50, 95%CI: 0.37-0.67, $P<0.001$). Having fever compared to not having fever (AOR=3.52, 95%CI: 1.95-6.37, $P<0.001$) and skin problem vs. no skin problem (AOR=3.45, 95%CI: 1.37-8.72, $P=0.01$) were associated with higher likelihood of accessing care at health facilities. However, having a headache was associated with lower likelihood (AOR= 0.47, 95%CI:0.27-0.92, $P=0.03$) of accessing care at health facilities. Children from the central region had a lower likelihood of accessing care at health facilities than those from northern and southern regions (Table 4).

The socio-economic factors like residence and wealth status were also associated with HSB. The children from urban areas had almost twice the likelihood of HSB than the children from the rural households (AOR=1.75, 95%CI: 1.12-2.72, $P=0.01$). Compared to children from poorer households, children from wealthier households were more likely to be taken for healthcare at health facilities (AOR=1.86, 95%CI: 1.25-2.78, $P=0.02$). Children with chronic conditions were more likely to be taken for care to health facilities than those without chronic conditions (AOR= 2.13, 96%CI: 1.23-3.68, $P=0.01$).

DISCUSSION

We investigated the health seeking behaviour of carers of a representative sample of children in Malawi using the Malawi IHS dataset. This is the first national-level study analyzing HSB due to a broad range of symptoms amongst the children of Malawi. In this study, there are five key findings: (a) 32% of the children had some symptoms in the past two weeks; (b) of these, 60% sought health care from a health care facility; (c) fever (47%), respiratory tract infections (15%) and headache (9%) were the three most common symptoms reported; (d) 75% of the children obtained healthcare from government health facilities while 14% sought health care from private clinics; and (e) type of illness, residence, age, region and wealth status were the main determinants for taking children to access care at health facilities.

In contrast to a study conducted in Tanzania, this study had 7% higher proportion of children with at least one illness in the past two weeks [18]. Similar to other studies in sub-Saharan Africa, fever is amongst the most common childhood illness [8] [19]. Some studies conducted in Sub-Saharan Africa (SSA) have also shown variations in HSB by symptoms and age [8] [19] [20]. Amongst those not seeking healthcare from a healthcare facility, a similar sizable majority consulting either drug sellers or using self-treatment was observed. Although this study found high HSB among children, approximately 16% lower than studies conducted among children with fever, cough and diarrhea in Ethiopia [8] [19]. Compared to some studies conducted in Ethiopia [21] [22], this study had higher HSB.

Similar to this study, the majority of the children that sought care were taken to government health facilities in studies done in SSA [8] [19]. The observed differences could be due to focusing on a subpopulation compared to general population in our case. Amongst the under-five children, this study has a slightly higher health seeking behavior than obtained in a Malawian study by Lungu et al [23]. Accessing care from private clinics ranged from 30% to 85% for one study involving children with pneumonia in SSA [24]; but the average proportion of children brought to care was higher than in this study (approximately 78%). Approximately, 1% of the children with pneumonia in one study covering Uganda, Nigeria, Ethiopia, Tanzania, Burkina Faso and Democratic Republic of Congo (DRC) [24] were taken to private clinics while in this study we found 14% of the children that were taken to private clinics. The differences in accessing care from private clinics may be attributable to country specific health system programming like subsidies of patient fees for faith-based facilities in Malawi – which may not be the case in the other countries.

There is not much literature in Africa on the association between HSB and skin disease. However, in one study conducted rural Tanzania indicated that HSB amongst the children with skin diseases was approximately 48% [18]. The major reason for higher HSB in the Malawian children may be attributable to free healthcare whilst in other countries patient fees apply. For example, in Tanzania most of the parents

took their children to traditional healers because the service was cheaper than at the government or faith-based health facilities [18].

We found weak evidence of association between HSB and sex of the child. However, a study conducted in Nigeria has shown that HSB was almost three-fold higher for boys than girls [25]. The weak evidence in association between HSB and child's sex in Malawi may be attributable to the implementation of child healthcare related byelaws in the country. One example of byelaw is imposing fines on women for delivering at home, in the form of goats, chickens and money [26] [27] or fining parents who do not take their children to health facilities once the children are sick.

There are several policy implications of the study findings. First, we noted that health seeking behaviour varied with age of the child. Specifically, we found that older children aged 5 to 14 years were less likely to be taken to a health facility as observed in some studies conducted in Malawi, Ghana and Nigeria [23] [28] [29]. Furthermore, children with fever had higher likelihood of HSB, as shown in similar studies [30] [31]. In Malawi, there was higher proportion of HSB amongst those with vomiting and diarrheal symptoms compared to Tanzania [32]. We also observed higher likelihood of HSB in Malawi than in Tanzania amongst the persons with fever or malaria compared with other symptoms [33]. There is a need to conduct further research in order to understand the barriers and facilitators of health care seeking behaviour amongst the care givers of children below 15 years in Malawi. Such a study needs to use both qualitative and quantitative methods of data collection.

Secondly, HSB was also lower in the rural areas compared to the urban areas. Of the total population in Malawi, 16% live in urban areas while 84% live in rural areas [34]. Therefore, the majority of Malawi may not be accessing health care from health facilities because the facilities are far from their homes. The low coverage of health services in rural areas of Malawi is often exacerbated by the high costs related to reaching health facilities [35]. Some similar studies in resource limited settings have cited distance to the facilities [36] or unavailability of health services to be associated with lower HSB amongst the rural populations [37]. A multi-country study conducted in SSA shows that people in Malawi took the least time to their nearest health facility compared to other countries [38]. However, amongst the rural populations, access to local health centers or hospitals is often constrained by a lack of transport and inability to meet the direct and indirect costs of a clinic visit [30]. One option to provide health services to the rural population may to provide more outreach clinics and provision of transport for children from hard-to-reach areas.

We also observed that children with chronic illnesses had a higher likelihood of being taken for care at health facilities. A study conducted in Malawi has shown that understanding of health and disease determined the decision to seek health care as well as the place to seek health care amongst persons with

chronic conditions in Malawi [39].

Some studies conducted in Sub-Saharan Africa have shown that HSB is associated with socio economics of the society[40] [41]. In this study we did find strong evidence of associations between wealth status of carers of children and the associated HSB. Similar to a study conducted in Nigeria [28], this study found that children from households of higher wealth status are more likely to access care at health facility and this may be attributable to the most of the rich households being able to pay for healthcare. Furthermore, most of the rich households can afford medical insurance hence they are more likely to take their children to accessing care at health facilities.

The major strengths of this study were the large sample size and its representativeness, which potentially allows the analysis to improve operational practice and inform policy change. The study findings have the potential to inform management of children in Malawi and other similar settings especially with regard to HSB of their caregivers. The study depended on reported information on symptoms of the child by the household key respondent, therefore, some symptoms may have been omitted either intentionally or due to recall lapse. However, in this study we are unable to estimate the extent of underestimation or overestimation of the reported symptoms and their associated HSB.

The other major limitation of the study includes only capturing up to two symptoms per child. The children may have had more than two symptoms and that minimized the actual interplay of the symptoms on likelihood for accessing care at health facilities. Furthermore, the IHS did not capture time it took for care to be sought hence we are unable to determine whether care was obtained late or promptly. The IHS did not capture the distance from the household to the nearest health facility where the child was more likely to be taken for healthcare for the illnesses although there is literature that shows that distance to health facility is associated with HSB. This analysis has not considered the effect of interactions between symptoms on HSB of parents and children. Besides, this analysis did not consider the caregiver perceptions, reasons to seek or not to seek health care services as such data were not available albeit crucial for understanding the HSB. We also recognize that the interviews were conducted at different times of the year and this has implications on the seasonal bias on the findings of the reported symptoms as well as their associated HSB. In this analysis, we have not taken into account seasonal variations of the reported symptoms as well as their associated HSB.

In conclusion, HSB for children in Malawi is common; children with fever, chronic conditions and skin problems had a higher likelihood of HSB while children aged 5 to 14 years and those with headache had lower probability of HSB than those aged 0 to 4 years. We also found that children from urban areas and households with higher wealth status were more likely to be taken for healthcare at health facilities. To achieve universal health coverage, government policies and programmes should take these factors into

account in health care programming in order to improve population health and reduce health inequalities in Malawi.

Availability of data and materials

Table 1: Characteristics of children reporting symptoms and health seeking behaviour of children within the past two weeks in Malawi: 2016

Characteristics	Total n (%) ^a	Illness reported in past two weeks n (%) ^b	Healthcare sought for illness reported n (%) ^c
Total	5350 (100.0)	1666 (31.7)	1008 (60.2)
Region			
<i>North</i>	612 (11.8)	185 (30.0)	132 (71.7)
<i>Central</i>	2304 (40.5)	816 (38.5)	467 (56.9)
<i>Southern</i>	2434 (47.7)	665 (26.3)	409 (61.2)
Residence			
<i>Rural</i>	4075 (82.8)	1331 (33.0)	768 (58.6)
<i>Urban</i>	1275 (17.2)	335 (25.1)	240 (70.7)
Sex			
<i>Male</i>	2564 (47.8)	794 (31.0)	475 (60.2)
<i>Female</i>	2786 (52.2)	872 (32.3)	533 (60.3)
Child age group (in years)			
<i>0-4</i>	1792 (33.1)	684 (38.0)	459 (66.3)
<i>5-14</i>	3558 (66.9)	982 (28.5)	549 (56.3)
Wealth status			
<i>Low</i>	2242 (44.9)	778 (35.1)	425 (54.8)
<i>Middle</i>	1170 (24.1)	349 (29.8)	217 (62.7)
<i>High</i>	1938 (31.0)	539 (28.2)	366 (68.1)
Relationship to household head			
<i>Child/niece/nephew</i>	5241 (98.2)	1649 (32.0)	997 (60.3)
<i>Brother/sister/cousin</i>	53 (0.9)	6 (14.9)	4 (57.8)
<i>Other relatives</i>	56 (0.9)	11 (18.1)	7 (56.8)
Age group of carer (in years)			
<i>15-34</i>	2464 (44.5)	811 (33.4)	509 (61.6)
<i>35-59</i>	2394 (45.7)	698 (30.2)	399 (58.2)
<i>60+</i>	492 (9.5)	157 (30.5)	100 (62.8)
Education level of carer			
<i>None</i>	4951 (94.4)		
<i>Primary</i>	194 (0.3)	1284 (32.1)	762 (59.1)

<i>Secondary</i>	174 (0.2)	283 (33.7)	179 (63.3)
<i>Missing</i>	31 (<0.1)	99 (23.2)	67 (70.3)

^aDenominator for column of those sick within the past 14 days (b)

^bDenominator for column of those who sought health care (c)

Table 2a: Symptoms and their associated health seeking behaviour amongst children in Malawi: 2016

Symptoms (n=1666)	Number of persons for each illness ^a		Number of persons that sought health care for each illness ^b	
	n	(%)	n	(%)
Fever	792	(47.6)	569	(71.1)
Respiratory tract	252	(15.1)	120	(46.6)
Headache	151	(9.1)	49	(32.6)
Stomach ache	128	(7.7)	60	(48.7)
Vomiting	88	(5.3)	57	(60.0)
Injury	79	(4.7)	34	(49.3)
Other*	67	(4.0)	44	(63.1)
Skin	64	(3.7)	47	(77.5)
Sore throat	59	(3.5)	34	(55.4)
Eye	22	(1.3)	14	(66.9)
Dental problem	6	(0.4)	2	(3.9)

*Fainting, Pain when Passing Urine, Mental Disorder, Tuberculosis, Unspecified Long-term Illnesses, and Other Illnesses

^aDenominator for “Number of children that were taken for health care”

^bNumerator for children whose carers reported the symptom

Table 2b: Number and percentage of children with chronic conditions in Malawi in 2016

Chronic condition (n=1666)	Number with condition	Percentage with Condition*
Total	231	13.9
Asthma	91	5.5
Fever	25	1.5
Epilepsy	24	1.4
Stomach Disorder	17	1.0
HIV/AIDS	11	0.7
Mental Illness	8	0.5
TB	4	0.2
Diabetes	3	0.2
Cancer	3	0.2
Pneumonia	3	0.2
Schistosomiasis	1	0.1
Arthritis	1	0.1

*Denominator for each of the chronic conditions is 1666 individuals that reported

TB= Tuberculosis

HIV/AIDS= Human Immunodeficiency Virus and Acquired Immunodeficiency Syndrome

Table 3: Places where care was sought amongst children with illnesses in Malawi: 2016

Action taken (n=1666)	n	%
Did not seek health care^a	93	5.6
<i>Did nothing, not serious illness</i>	63	3.8
<i>Did nothing, had no money</i>	30	1.8
Sought health care	1573	94.4
(a) Care at health facility^b	1008	60.4
Government health facility	757	45.4
CHAM health facility	51	3.1
Private health facility	146	8.8
Village clinic	28	1.7
Local pharmacy*	26	1.6
(b) Care not at health facilities^c	566	34.0
Used medicine had in stock	105	6.3
Personally, known remedies	19	1.1
Grocery	408	24.5
Traditional healer	8	0.5
Faith healer	13	0.8
Other	13	0.8

CHAM=Christian Health Association of Malawi

^bThese constitute healthcare seeking behaviour (HSB)

^{a,c}These do not constitute healthcare seeking behaviour (HSB)

*Pharmacists provide some level of health care advice so we considered this as health care seeking behaviour. Using drug at home or buying from a grocery store does not involve receiving any health care advice.

Table 4: Factors associated with health seeking behaviour amongst children in Malawi for whom at least one symptom was reported: 2016

Characteristics (n= 1666)	Crude		Adjusted	
	OR (95%CI)	P-value*	OR (95%CI)	P-value*
Region
