#### Abstract

This paper presents a statistical approach for identifying the significant impact of cracks on the 8 9 output power performance for photovoltaic (PV) modules. There are a few data statistical analysis 10 for investigating the impact of cracks in PV modules in real-time long-term field data 11 measurements. Therefore, this paper will demonstrate a statistical analysis approach which uses 12 T-test and F-test for identifying whether the crack has a significant or non-significant impact on the total amount of power generated by the PV modules. Electroluminescence (EL) method is used 13 14 for scanning possible faults in the examined PV modules. However, Virtual Instrumentation (VI) 15 LabVIEW software is used to simulate the theoretical I-V and P-V curves. The approach classified only 60% of cracks that has a significant impact on the total amount of power generated by PV 16 modules. 17

- 18 Keywords: Photovoltaic (PV) Module Performance; Solar cell cracks; Statistical Approach;
- 19 Electroluminescence (EL); Surface Analysis

# 20 1. Introduction

- 21 Cell cracks appear in the photovoltaic (PV) panels during their transportation from the factory to
- 22 the place of installation. Also, some climate proceedings such as snow loads, strong winds and
- 23 hailstorms might create some major cracks on the PV modules surface [1-3]. These cracks may
- lead to disconnection of cells parts and, therefore, to a loss in the total power generated by the PV
- 25 modules [4].
- 26 There are several types of cracks that might occur in PV modules: diagonal cracks, parallel to
- busbars crack, perpendicular to busbars crack and multiple directions crack. Diagonal Cracks and
- multiple directions cracks always show a significant reduction in the PV output power [5].
- 29 Moreover, the PV industry has reacted to the in-line non-destructive cracks by developing new
- 30 techniques of crack detection such as resonance ultrasonic vibration (RUV) for screening PV cells
- with pre-existing cracks [6]. This helped to reduce cell cracking due to defective wafers, but, it
- does not mitigate the cracks generated during the manufacturing process of PV modules.
- When cracks appear in a solar cell, the parts separated from the cell might not be totally
- disconnected, but the series resistance across the crack varies as a function of the distance between
- 35 the cell parts and the number of cycles for which module is deformed [7]. However, when a cell
- part is fully isolated, the current decrease is proportional to the disconnected area [8, 9].

- 37 Collecting the data from damaged PV modules using installed systems is a challenging task.
- 38 Electroluminescence (EL) imaging method is used to scan the surface of the PV modules, the light
- output increases with the local voltage so that regions with poor contact show up as dark spots [10,
- 40 11]. The thermography technique is simpler to implement, but the accuracy of the image is lower
- 41 than with the EL technique, and does not allow the estimation of the area (in mm<sup>2</sup>) that is broken
- in the solar cells [12, 13]. Therefore, in this paper we have used EL imaging method which can be
- illustrated and discussed briefly in the following articles [14-16].
- 44 As proposed in [17] the performance of PV systems can be monitored using virtual instrumentation
- 45 software such as LabVIEW. Also MATLAB software allows users to create tools to model,
- 46 monitor and estimate the performance of photovoltaic systems. The simulation tool is important
- 47 to compare the output measured data from PV module with its own theoretical performance [18].
- There are a few statistical analysis tools that have been deployed in PV applications. The common
- used tool is the normal standard deviation limits ( $\pm$  1 SD or  $\pm$  3 SD) technique [19]. However, [20]
- used a statistical local distribution analysis in identifying the type of cracks in a PV modules. To
- 51 the best of our knowledge, few of the reviewed articles have used a real-time long-term statistical
- 52 analysis approach for PV cracked modules under real-time operational process. Therefore, the
- main contribution of this work can be illustrated as the following:
  - Development of a novel statistical analysis approach that can be used to identify the significant effect of cracks on the output power performance for PV modules under various environmental field data measurements.
  - Proving that not all cracks has a significant impact on the PV output power performance.
- This paper is organized as follows: Section 2 describes the methodology used which contains the
- 59 data acquisition, PV modules cracks and the statistical analysis approach, while Section 3 lists the
- output results of the entire work. The discussion is presented in section 4. Finally, Sections 5 and
- 61 6 describes the conclusion and the acknowledgment respectively.

## 62 2. Methodology

54

55

56 57

63

#### 2.1. Data acquisition

- In this work, we used a statistical study of broken cells showing different crack types. Several test
- 65 measurements are carried out on two different PV plants at the University of Huddersfield, United
- 66 Kingdom. The first system consists of 10 polycrystalline PV modules with an optimum power
- 67 220Wp. However, the second system consists of 35 polycrystalline with 130Wp each. Both
- systems are shown in Fig. 1.
- As presented in Fig. 1(A) and Fig 1(B), there are two examined PV systems with total amount of
- 70 PV modules equal to 45. To establish the connection for each PV module separately, a controlling
- unit is designed to allow the user to connect any PV module to a FLEXmax 80 MPPT. In order to
- facilitate a real-time monitoring for each PV module, therefore, Vantage Pro monitoring unit is
- used to receive the Global solar irradiance measured by Davis weather station which includes
- 74 pyranometer. Hub 4 communication manager is used to facilitate acquisition of modules
- 75 temperature using Davis external temperature sensor, and the electrical data for each photovoltaic

- module. LabVIEW software is used to implement the data logging and monitoring functions of the examined PV modules.
- 78 Fig. 1(C) shows the data acquisition system. Furthermore, Table I illustrates both electrical
- 79 characteristics of the solar modules that are used in this work. The standard test condition (STC)
- for all examined solar panels are: Solar Irradiance = 1000 W/m<sup>2</sup>; Module Temperature = 25 °C.

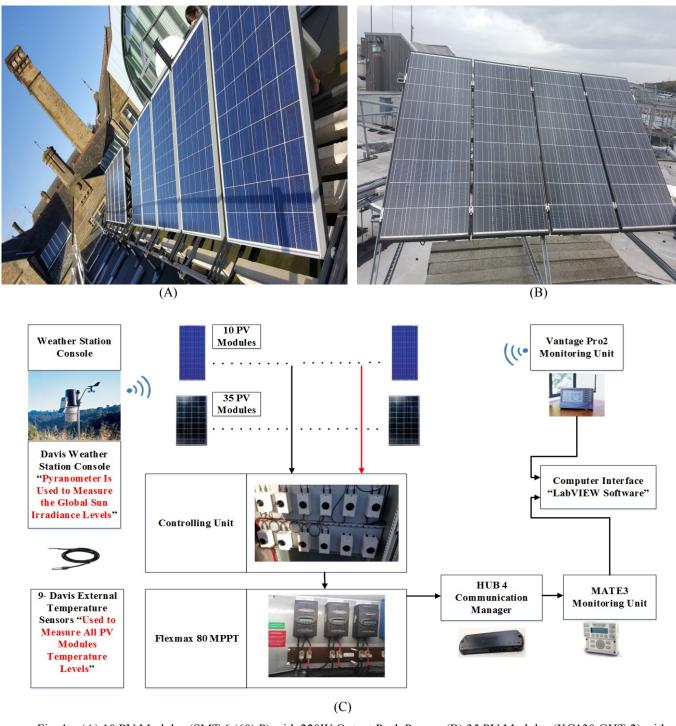

Fig. 1. (A) 10 PV Modules (SMT 6 (60) P) with 220W Output Peak Power; (B) 35 PV Modules (KC130 GHT-2) with 130W Output Peak Power; (C) Monitoring the Examined PV System Using LabVIEW Software

TABLE I ELECTRICAL CHARACTERISTICS FOR BOTH PV SYSTEMS MODULES

Solar Panel Electrical Characteristics	1 <sup>ST</sup> System: PV Module, SMT 6 (60) P	2 <sup>nd</sup> System: PV Module, KC130 GHT-2	
Peak Power	220 W	130	
Voltage at Maximum Power Point $(V_{mp})$	28.7 V	17.6

Davis Pyranometer Sensor Tilt Angle and Azimuth Angles (North-South)	42°, 185°	42°, 180°	

# 2.2. Electroluminescence setup and PV modules cracks

The electroluminescence system developed is presented in Fig. 2(A). The system is comprised of a light-tight black-box where housed inside is a digital camera and a sample holder. The digital camera is equipped with a standard F-mount 18–55 mm lens. To allow for detection in the near infrared, the IR filter was removed and replaced with a full spectrum window of equal optical path length. In our setup a Nikon D40 was used, but in principle any digital camera with similar grade CCD or CMOS sensor and where the IR filter can be removed would serve the purpose. The bias was applied and the resultant current and the voltage are measured by a voltage and current sensors which are wirelessly connected to the personal computer (PC). The purpose of the PC is to get the electroluminescence image of the solar module and predicting the theoretical output power performance of the PV module.

In order to reduce the noise and increase the accuracy, all EL images are processed by removing background noise and erroneous pixels. Firstly, background image has been captured under the same conditions as the EL images but without forward biasing the cell. This background image is subtracted from each EL image in order to reduce the image noise level. The images are cropped to the appropriate size and in the case of high resolution imaging system the captured cell images are compiled together to form an image of the entire module. Additionally, to increase the accuracy and the vision of the EL image, each PV module cell is captured separately.

In order to determine the cracks location, type and size; reflex camera has been used for imaging possible cracks in each PV module. As explained previously in the introduction, EL imaging technique is used worldwide and it has been demonstrated by many researchers [14-16]. Broken cells are sorted according to the type of crack, Fig. 2 shows all examined crack types which are classified as the following:

- 104 A. Diagonal crack  $(+45^{\circ})$ 
  - B. Diagonal crack (- 45<sup>0</sup>)
- 106 C. Parallel to busbars crack
- D. Perpendicular to busbars crack
- E. Multiple directions crack

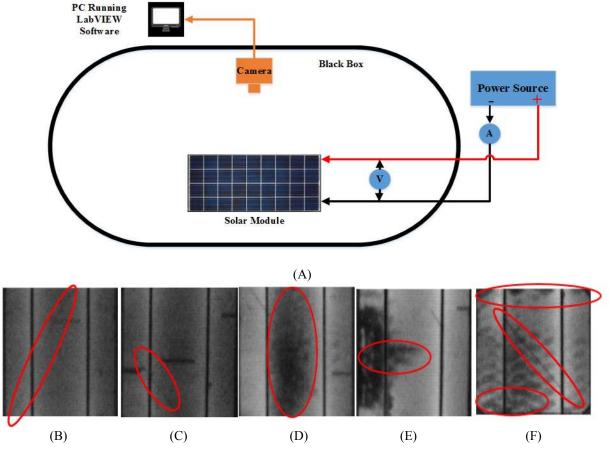

Fig. 2. El Experimental Setup and Examined Crack Types. (A) Electroluminescence experimental setup; (B) Diagonal Crack (+45°); (C) Diagonal Crack (-45°); (D) Parallel to Busbars Crack; (E) Perpendicular to Busbars Crack; (F) Multiple Directions Crack

# 2.3. Theoretical output power modelling

109

119

120

121

122

The DC-Side for all examined PV modules is modelled using 5-parameters model. The voltage and the current characteristics of the PV module can be obtained using the single diode model [21] as the following:

$$I = I_{ph} - I_o \left( e^{\frac{V + IR_S}{nsV_t}} - 1 \right) - \left( \frac{V + IR_S}{R_{sh}} \right) \tag{1}$$

Where  $I_{ph}$  is the photo-generated current at STC,  $I_o$  is the dark saturation current at STC,  $R_s$  is the module series resistance,  $R_{sh}$  is the panel parallel resistance, ns is the number of series cells in the PV module and  $V_t$  is the thermal voltage and it can be defined based on:

$$V_t = \frac{AKT}{q} \tag{2}$$

Where A the diode ideality factor, k is Boltzmann's constant and q is the charge of the electron.

The five parameters model are determined by solving the transcendental equation (1) using Newton-Raphson algorithm. Based only on the datasheet of the available parameters shown previously in Table I. The power produced by PV module in watts can be easily calculated along with the current (I) and voltage (V) that is generated by equation (1), therefore, P<sub>theoretical</sub> = IV.

## 2.4. Statistical analysis approach

123

- After examining all PV modules which have cracks, a real time simulation can be processed. A
- statistical analysis approach is used to determine whether the PV crack has a significant impact on
- the total generated output power performance or not. Two statistical methods are used, T-test and
- F-test. The first method (T-test) is used to compare the simulated theoretical power with the
- measured PV output power. T-test can be evaluated using (3) where  $\bar{x}$  is the mean of the samples,
- $\mu$  is the population mean, n is the sample size and SD is the standard deviation of the entire data.
- In this work, we have used a confidence interval for all measured samples equal to 99%.
- 131 Statistically speaking, the crack does not have a significant impact on the output power
- performance if the t-test value is significant, which means that the t-test value is less than or equal
- to 2.58 as shown in Table II.
- 134 If the t-test value is not significant, another statistical method/layer is used to compare the output
- measured power from the cracked PV module with a PV module that has 0% of cracks. This layer
- is used to confirm that the output generated power of the cracked PV module has a significant
- impact (Real Damage) on the total generated output power performance of the examined
- photovoltaic module. In section 4 (results section), most of the inspected results indicates that if
- the T-test value is significant, F-test value is also significant. The overall statistical approach can
- be explained in Fig. 3 and F-test can be evaluated using (4). The explained variance is calculated
- using between groups mean square value, the unexplained variance is calculated using within
- groups mean square value [22].
- Table III, illustrates the expected output results from F-test using 99% (P=0.01) confidence
- interval. In this work, an infinite number of samples (Total measured samples > 120) is used to
- determine whether the F-test value is significant (F-test  $\leq$  6.635) or not significant (F-test  $\geq$  6.635).

$$t = \frac{(\overline{x} - \mu)\sqrt{n}}{SD} \tag{3}$$

$$F = \frac{Explained \, Variance}{Unexplained \, Variance} \tag{4}$$

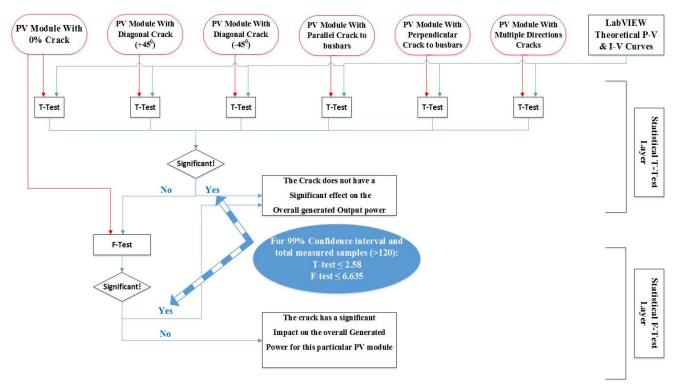

Fig. 3. Statistical Approach Used to Identify Whether the Crack Type has a Significant Impact on the Output Power Performance of a Photovoltaic Module

TABLE II FATISTICAL T-TEST CONFIDENCE INTERVAL [22]

	120	4.787
	$\infty$	6.635

#### 3. Results

149

150

#### 3.1. Cracks distribution

- As described previously, the statistic micro cracks location, type and size was established by taking
- EL images of 45 PV modules. The EL images are taken with a reflex camera [23]. From the
- captured pictures, the number of cracked cells in each module is counted as shown in Fig. 4.
- Broken cells are sorted according to the type of crack they show and the classification already
- presented in Fig. 2. The probability for a cell to be cracked and the crack-type distribution are
- presented in Fig. 4. Only 15.556% of the total PV modules have no cracks. However, 84.444% of
- the PV modules contains at least one type of the crack: diagonal (26.666%), parallel to busbars
- 158 (20%), perpendicular to busbars (8.888%) or multiple directions crack (28.888%).
- According to the statistical approach explained previously in Fig. 3, T-test and F-test methods are
- significant based on a threshold values. Therefore, we have divided all crack-types into two main
- 161 categories:

162

163

164

165166

167

168

169

- Short: Crack effects one solar cell in a PV module
- Long: Crack effects two or more solar cell in a PV module

Furthermore, fitted line regression is used for the entire measured PV crack-type data. A fitted regression represents a mathematical regression equation for the PV measured data. We have selected the fitted regression lines to illustrate the relationship between a predictor variable (Measured PV Power) and a response variable (Irradiance Level) and to evaluate whether the model fits the data. If the measured PV power data is very close to the fitted line regression model, therefore, there is a significant relationship between the predictor with the response variable.

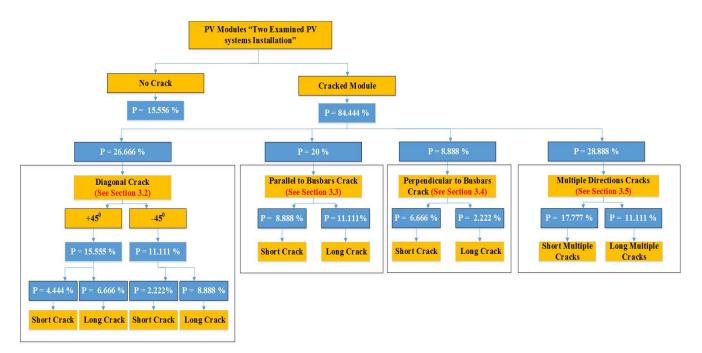

Fig. 4. Crack Types Probability Distribution among Both Examined PV Systems (45 PV Modules)

# 3.2. Diagonal cracks

170

- Diagonal cracks can be classified into two different categories: +45° and -45° as shown in Fig. 2(A)
- and 2(B) respectively. The measured data which has been carried out from both diagonal crack
- categories indicate that there is a huge similarity in the measured output power performance for
- all examined PV modules. Therefore, we have classified both categories in one crack type. This
- result is different from the results explained in [7, 8] because all the measured data in our
- experiments were taken from a real-time long-term environmental measurements instead of
- 177 laboratory climate conditions.
- Using the statistical approach, the T-test values for all examined diagonal crack PV modules (12)
- PV modules) are shown in Table IV. Since the T-test value for a diagonal crack effects 1 or 2 solar
- cells is less than 99% of the confidence interval threshold (2.58), the output power performance
- for the PV module is statistically not significant: No evidence for a real damage in the PV module.
- The F-test for a diagonal crack effects 1 or 2 solar cells is equal to 4.55 and 5.67 respectively. The
- mathematical expressions for the fitted line regression are illustrated in Table IV.
- A real-time long-term measured data for a full day is carried out to estimate the output power
- performance for a diagonal crack which effects 1 and 5 solar cells are presented in Fig. 5(A). The
- theoretical simulated output power which is calculated using LabVIEW software has a standard
- deviation equals to 61.46 which is very close to the standard deviation for a diagonal crack which
- effects 1 solar cell (SD=61.38). However, a diagonal crack effects 5 solar cells has a huge reduction
- in the output power performance of the PV module where the standard deviation is equal to 60.99.
- 190 Finally, the measured output power of the PV module matches the theoretical output power,
- therefore, the theoretical power in Fig. 5(A) cannot be seen, this results is also occurring in Fig.
- 192 6(A), Fig. 7(A) and Fig. 8(A).
- Fig. 5(B) describes the output power efficiency for the examined diagonal cracks effects 1, 2, 3, 4
- and 5 solar cells. Between 0.35 0.44% reduction of power estimated for a diagonal crack effects
- 195 1 solar cell. However, the estimated reduction of power for a diagonal crack effects 5 solar cells is
- between 2.97 5.37%. The output power efficiency can be estimated using (5).

Table IV

Diagonal Cracks Performance Indicators

Diagonal Crack	Number of Effected Solar Cells	Approximate Area Broken (mm)	T-test Value	Significant/Not Significant Effect on the PV Power Performance	Fitted Line Regression Equation
Short +45 <sup>0</sup> OR Short -45 <sup>0</sup>	1	1 mm <sup>2</sup> – 83 mm <sup>2</sup>	0.40 - 0.66	Not Significant	$P_{TH} = 0.1424 + 1.001 P_{Meas}$
Long +45 <sup>0</sup>	2	85.85 mm <sup>2</sup> – 169.7 mm <sup>2</sup>	1.22 – 1.86	Not Significant	$P_{TH} = 0.2875 + 1.003  P_{Meas}$
OR	3	172.7 mm <sup>2</sup> - 256.6 mm <sup>2</sup>	2.51 - 2.71	Significant	$P_{TH} = 0.5125 + 1.006 P_{Meas}$
Long -45 <sup>0</sup>	4	257. 5 mm <sup>2</sup> - 344.4 mm <sup>2</sup>	2.65 – 2.70	Significant	$P_{TH} = 0.7034 + 1.008  P_{Meas}$
	5	345.1 mm <sup>2</sup> – 424.3 mm <sup>2</sup>	3.12 – 3.35	Significant	$P_{TH} = 1.151 + 1.013  P_{Meas}$

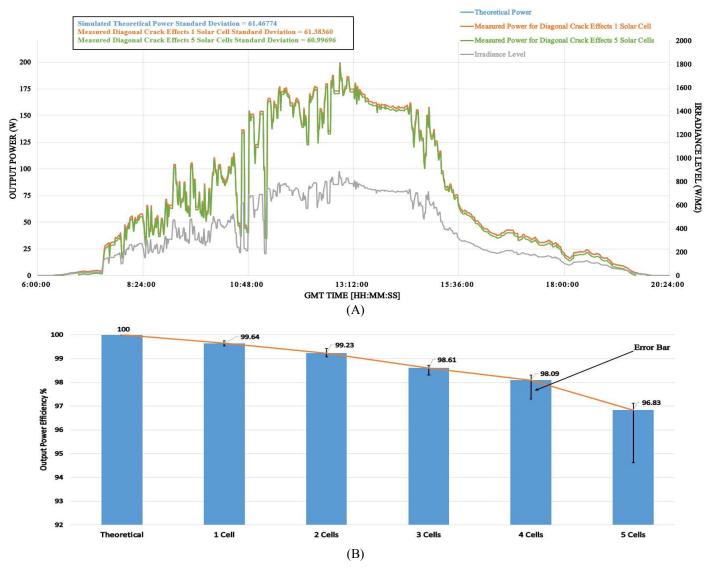

Fig. 5. (A) Real-Time Long-Term Measured Data for a Diagonal Crack Effects 1 and 5 Solar Cells; (B) Output Power Efficiency for a Diagonal Cracks Which Effects 1, 2, 3, 4 and 5 PV Solar Cells

#### 3.3. Parallel to busbars cracks

As explained previously in Fig. 5, parallel to the busbars cracks has a percentage of occurrence 20% (9 PV modules out of 45 examined PV modules) and they are listed as the following:

- 8.888% (4 PV modules): Short Crack Effect
- 11.111% (5 PV modules): Long Crack Effect

Not all parallel to busbars cracks has a significant impact/reduction on the output power performance of the PV module. As shown in Table V, parallel to busbars cracks effects 1 solar cell statistically indicates that there is no real damage in the PV module, the result is confirmed by the T-test value which is less than the threshold value 2.58. Moreover, when a parallel to busbars crack effects 2 solar cells with approximate broken area less than 82mm² have no significant effect on the amount of power generated by the PV module. Additionally, Table V illustrates various

mathematical equations for the measured fitted line regression which describes the relationship between the theoretical and measured output power.

Fig. 6(A) presents real-time measured data for a parallel to busbars crack effects 1 and 4 solar cells. The standard deviation for the theoretical simulated power is 62.01 which is very close to the standard deviation for a parallel to busbars crack effects 1 solar cell (61.8). However, parallel to busbars crack effects 5 solar cells has a huge reduction in the output power performance of the PV module while the standard deviation is equal to 61.09.

Fig. 6(B) describes the output power efficiency for the examined parallel to busbars cracks effects 1, 2, 3 and 4 solar cells. The reduction of power estimated for a parallel to busbars crack effects 1 solar cell is between 0.75% - 0.97%. However, the estimated reduction of power for a parallel to busbars crack effects 3 and 4 solar cells is between 2.39% - 3.0% and 3.67% - 4.55% respectively.

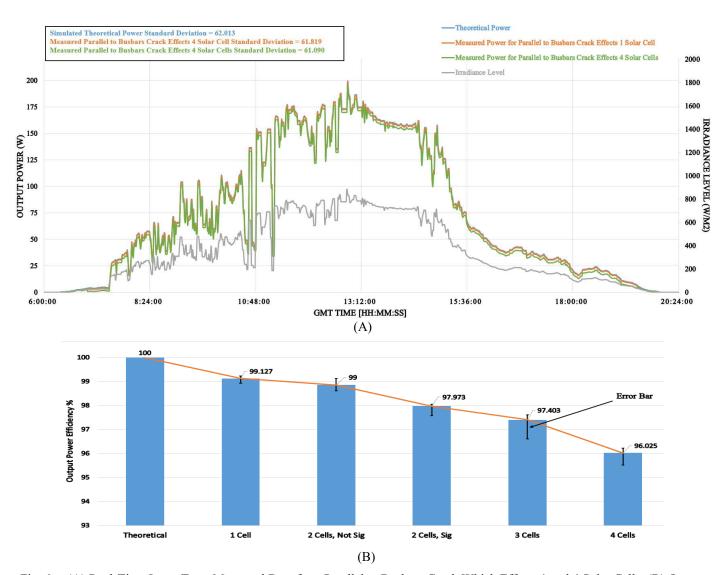

Fig. 6. (A) Real-Time Long-Term Measured Data for a Parallel to Busbars Crack Which Effects 1 and 4 Solar Cells; (B) Output Power Efficiency for Parallel to Busbars Crack Which Effects 1, 2, 3 and 4 PV Solar Cells

$$Efficiency = \frac{Meaured\ Output\ Power}{Theoretical\ Output\ Power} \times 100\%$$
 (5)

Table V
Parallel to Busbars Cracks Performance Indicators

		Solar Cells	(mm)	37.1	Significant Effect on	
				Value	the PV Power	
					Performance	
	Short	1	1 mm <sup>2</sup> – 59.2 mm <sup>2</sup>	0.78 – 1.13	Not Significant	$P_{TH} = 0.3002 + 1.001 P_{Meas}$
	Short	1	7 111111 37.2 111111	0.70 1.13	1 tot Significant	17H = 0.3002   1.0011 Meas
Parallel		2	63 mm <sup>2</sup> – 81 mm <sup>2</sup>	1.42 – 1.87	Not Significant	$P_{TH} = 0.3990 + 1.004  P_{Meas}$
To Busbars			82 mm <sup>2</sup> – 121 mm <sup>2</sup>	2.62 – 2.74	Significant	$P_{TH} = 0.6923 + 1.008  P_{Meas}$
	Long	3	122 mm <sup>2</sup> – 177 mm <sup>2</sup>	4.04 – 4.81	Significant	$P_{TH} = 0.9218 + 1.010 P_{Meas}$
		4	177.3 mm <sup>2</sup> – 239.7 mm <sup>2</sup>	4.39 – 5.66	Significant	$P_{TH} = 1.3590 + 1.016 P_{Meas}$

# 219 3.4. Perpendicular to busbars cracks

- 220 Perpendicular to busbars cracks usually do not occur in PV modules. In research have
- 221 distinguished only 4 PV modules from 45 to be classified as a perpendicular to busbars cracks.
- This result has been verified by many articles such as [7, 8]. Table VI shows all numerical results
- which are measured from the examined PV modules.
- Table VI indicates that a perpendicular to busbars crack effects 1, 2 and 3 busbars statistically has
- 225 no significant impact on the overall amount of power produced by a PV module. The measured
- results for a perpendicular to busbars cracks effects 1 and 4 solar cells can be seen in Fig. 7 (A),
- 227 the difference between the theoretical standard deviation and a perpendicular to busbars cracks
- 228 which effects 4 solar cells is equal to 1.014. Finally, Fig. 7(b) illustrates the output power efficiency
- measured for a perpendicular to busbars which effects 1, 2, 3 and 4 solar cells (1-8 Busbars), where
- the maximum power reduction is estimated for 8 busbars between 4.6 4.1%.

Table VI
Perpendicular to Busbars Cracks Performance Indicators

	Short	1	1	$1 \text{ mm}^2 - 16.2 \text{ mm}^2$	0.65 - 0.82	Not Significant	$P_{TH} = 0.0927 + 1.001 P_{Meas}$
			2	$16.3 \text{ mm}^2 - 60 \text{ mm}^2$	0.92 – 1.31	Not Significant	$P_{TH} = 0.1524 + 1.002  P_{Meas}$
		2	3	61.3 mm <sup>2</sup> – 78.5 mm <sup>2</sup>	1.43 – 1.96	Not Significant	$P_{TH} = 0.3604 + 1.004  P_{Meas}$
Perpendicular			4	$79.4 \text{ mm}^2 - 120 \text{ mm}^2$	2.52 – 2.77	Significant	$P_{TH} = 0.4678 + 1.005  P_{Meas}$
To Busbars	Long	3	5	$120.5 \text{ mm}^2 - 137.4 \text{ mm}^2$	2.83 – 2.94	Significant	$P_{TH} = 0.7397 + 1.008  P_{Meas}$
			6	$138 \text{ mm}^2 - 179.8 \text{ mm}^2$	2.79 – 3.11	Significant	$P_{TH} = 0.9265 + 1.010  P_{Meas}$
		4	7	$181.5 \text{ mm}^2 - 195 \text{ mm}^2$	3.02 - 3.27	Significant	$P_{TH} = 1.0790 + 1.012 P_{Meas}$
			8	$196.2 \text{ mm}^2 - 240.2 \text{ mm}^2$	3.10 – 3.55	Significant	$P_{TH} = 1.4590 + 1.018  P_{Meas}$

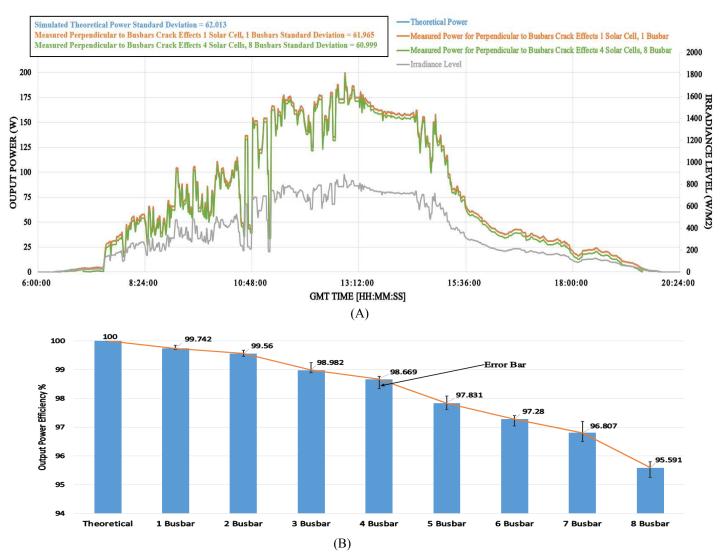

Fig. 7. (A) Real-Time Long-Term Measured Data for a Perpendicular to Busbars Crack Effects 1 and 4 Solar Cells; (B) Output Power Efficiency for a Perpendicular to Busbars Crack Which Effects 1, 2, 3 and 4 (1-8 busbars) PV Solar Cells

# 3.5. Multiple directions crack

Multiple directions cracks have the highest degradation in the PV measured output power. Three different measured data are presented in Fig. 8(A). As illustrated in Fig. 8(B), multiple directions crack effects 5 solar cells reduce the power efficiency of the PV module up to 8.42%. However, the average reduction in the power for a multiple directions crack effects 1 solar cell with an approximate broken area less than 46.2 mm<sup>2</sup> is equal to 1.04%.

Table VII shows a brief explanation for the T-test values and whether a multiple directions crack has a significant or not significant impact on the total output power produced by a cracked PV module.

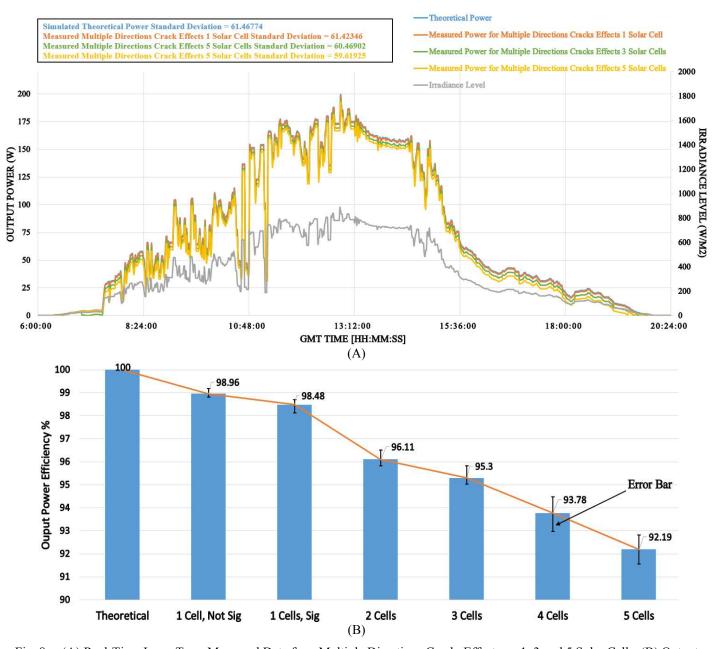

Fig. 8. (A) Real-Time Long-Term Measured Data for a Multiple Directions Crack Effects on 1, 3 and 5 Solar Cells; (B) Output Power Efficiency for a Multiple Directions Crack Which Effects 1,2,3,4 and 5 PV Solar Cells

Multiple Directions Cracks Performance Indicators

	Number of Effected Solar Cells	Approximate Area Broken (mm)	T-test Value	Significant/Not Significant Effect on the PV Power Performance	Fitted Line Regression Equation
Multiple		1 mm <sup>2</sup> – 45 mm <sup>2</sup>	2.06 – 2.44	Not Significant	$P_{TH} = 0.3679 + 1.004 P_{Meas}$
Directions	1	46.2 mm <sup>2</sup> – 1000 mm <sup>2</sup>	2.68 – 2.88	Significant	$P_{TH} = 0.5330 + 1.005  P_{Meas}$
Crack	2	$100 \text{ mm}^2 - 3700 \text{ mm}^2$	3.25 – 3.33	Significant	$P_{TH} = 1.028 + 1.012  P_{Meas}$
	3	$170 \text{ mm}^2 - 5000 \text{ mm}^2$	4.70 – 4.88	Significant	$P_{TH} = 1.554 + 1.019  P_{Meas}$
	4	223 mm <sup>2</sup> – 8200 mm <sup>2</sup>	6.17 – 6.31	Significant	$P_{TH} = 2.015 + 1.027 P_{Meas}$
	5	$400 \text{ mm}^2 - 9800 \text{ mm}^2$	7.30 – 7.52	Significant	$P_{TH} = 2.577 + 1.033  P_{Meas}$

#### 4. Discussion

#### 4.1. Overall cracks assessment

The observed modules have 38 PV modules with various crack-types. The probability of occurrence for each crack type can be seen in Fig. 4. Before considering the statistical approach, it is hypothetically true to say that 84.4% has a significant impact on the output power performance. However, the statistical approach has confirmed that this is incorrect, because only 60% has a significant impact on the output power performance for all examined PV modules.

This result can be investigated further more by applying the same statistical approach on various PV systems in different regions around the world. The only difference might be the confidence interval limitations (99%, 95% and 90%) due to the various accuracy rates for the instrumentation used in the PV systems such as the Voltage sensors, Current sensors and Temperature sensors.

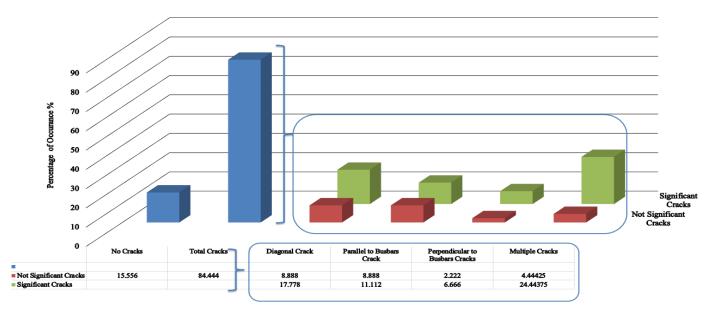

Fig. 19. Percentage of Cracks in the Examined PV modules, overall significant Cracks equals to 60% out of 84.444%

# 4.2 Surface damage

For better understanding how some cracks effects the surface of the PV modules, we have created a MATLAB code which can simulate the measured data of a cracked PV module in order to evaluate the surface shape for a particular crack-type using Surf(x, y, z) MATLAB function [24].

Fig. 10(A) shows a diagonal crack (+45°) effects 3 solar cells. It is clear that the surface of three different solar cells are damaged (Noted as 1, 2 and 3). The degradation of the power for the solar cells is between 0.5 and 1 Watt. Overall PV module efficiency can be estimated by the MATLAB code which is equal to 98.61%, this result can be illustrated in Figs. 5(B) and 10(A).

Similarly, Fig 10(B) describes the surface shape of a parallel to busbars crack which effects 3 solar cells. The degradation of the power in the affected solar cells is between 2.5 and 2 Watt. The

overall power efficiency of the PV module is equal to 97.41% which is very similar to the value (97.4%) described earlier in Fig. 6(B).

The surface shape for a perpendicular to busbars crack effects 3 solar cells, 6 Busbars is illustrated in Fig. 10(C). However, Fig. 10(D) shows a cracked surface for a PV module that is affected by a multiple directions crack on 3 different solar cells. Moreover, a perpendicular crack effects a solar cell with 2 busbars has an estimated degradation of power equals to 1.5 Watt. Overall efficiency of the cracked surfaces is equal to 97.28% for a perpendicular to busbars crack which effects 3 solar cells (6 busbars), and 95.3% for a multiple directions crack which effects 3 solar cells.

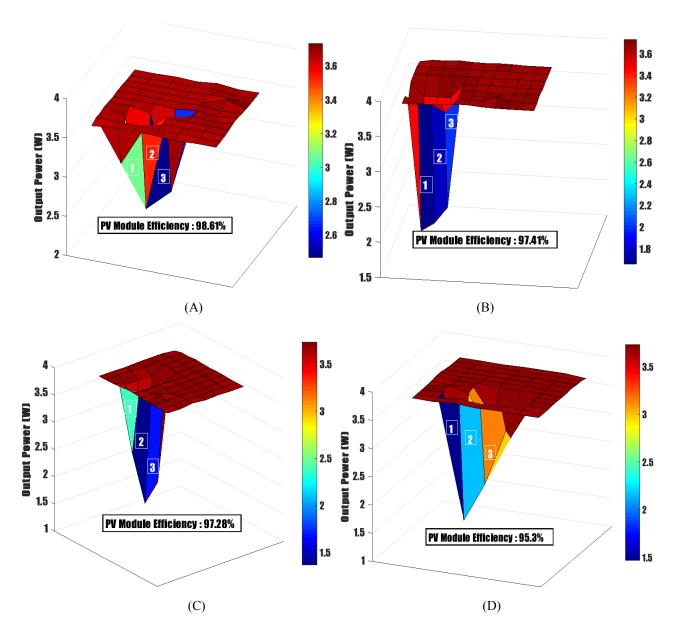

Fig. 10. (A) Surface Shape for a Diagonal (+45°) Crack Effects 3 Solar Cells; (B) Surface Shape for a Parallel to Busbars Crack Effects 3 Solar Cells (C) Surface Shape for a Perpendicular to Busbars Crack Effects 3 Solar Cells, 6 Busbars; (D) Surface Shape for a Multiple Directions Crack Effects 3 Solar Cells

#### **5.** *Conclusion*

- 270 This paper propose a new statistical algorithm to identify the significant of the cracks on the output
- power performance of the PV modules. The algorithm is developed using a Virtual Instrumentation
- 272 (VI) LabVIEW software. We have examined 45 PV modules with various crack-type such as
- 273 diagonal, parallel to busbars, perpendicular to busbars and multiple directions crack.
- Before considering the statistical approach, 84.44% of the examined PV modules have a significant
- impact on the output power performance. However, the statistical approach has confirmed that this
- 276 result is incorrect, since only 60% of the examine PV cracks have a significant impact on the output
- power performance.
- Based on the measured output power data of each crack-type PV module, we have evaluated the
- 279 fitted line regression equations. Subsequently, the surface of cracked PV modules have been
- demonstrated using Surf(x, y, z) MATLAB Function.
- For further work, we are designing a generic algorithm based on statically analysis techniques to
- detect multiple faults in PV systems such as DC-Side faults, AC-Side faults, PV cracks and shading
- 283 effect.
