Abstract This updated systematic review assesses the effects of pharmacological interventions for drug-using offenders.

Methods Systematic review protocols and conventions of the Cochrane Collaboration were followed to identify eligible studies. Studies were pooled in a meta-analysis to assess the impact of pharmacological interventions on drug use and criminal activity. An economic appraisal was conducted.

Results The search strategies identified 22 studies containing 4372 participants. Meta-analyses revealed a small statistically significant mean difference favouring pharmacological interventions relative to psychological interventions in reducing drug use and criminal activity. When comparing the drugs to one another there were no significant differences between those included (methadone versus buprenorphine, naltrexone and cyclazocine).

Conclusion Overall, the findings of this review suggest that methadone and naltrexone may have some impact on reducing drug use and reincarceration. Individual pharmacological drugs had differing (generally non-significant) effects. One study identified serious adverse events. Three studies reported cost and consequences information sufficient to conduct a full economic analysis but this was not comprehensive enough to be able to make judgements across all treatment options. Full economic analyses should be encouraged. The study findings were limited mainly to male adult offenders.

Keywords Systematic review · Drug treatment · Economic appraisal · Offenders · Crime

Introduction

Offenders as a socially excluded group of people demonstrate significant drug use and subsequent health problems. Studies investigating the prevalence of drug dependence in UK prisons report variable figures of 10% (Gunn et al., 1991), 39% (Brooke et al., 1996) and 33% (Mason et al., 1997). In a review article, the estimated prevalence of drug abuse among male and female prisoners was estimated to be 10 to 48% and 30 to 60%, respectively (Fazel et al., 2006). A recent survey carried out on the Swedish criminal justice system found that 70% of all individuals had substance abuse problems (including alcohol, drugs or both), with a slightly lower percentage among females compared with the whole group (67%) (Klientkartlagningen, 2015). These numbers can be compared with the general population in Sweden where 1% of all men and 0.5% of all women fulfil the criteria for drug dependence or abuse (Ramstedt et al., 2013). Similar trends have been reported elsewhere. In France, 30% of prison inmates are heroin addicted, and in Australia, 59% of prison inmates report injecting (primarily heroin) drug use histories. In 2018 in the USA, an estimated 6,410,000 persons were held in prisons or jails, or were on probation or parole (Maruschak and Minton, 2020). Of the prison population, 85% are likely to have an active substance use disorder or were incarcerated for a crime involving drugs or drug use according to the US National Institute on Drug Abuse (National Institute on Drug Abuse (NIDA), 2020). In the US, it is recognised that many offenders need treatment to tackle their drug use (Lo and Stephens, 2000). The link between drug use, subsequent health, social and criminological consequences is well documented in the literature (Michel and Maguet, 2005), and offenders have a high risk of death from opioid overdose within 2 weeks of release from prison (Binswanger et al., 2007, Bird and Hutchinson, 2003, Kinner et al., 2013, Merrall et al., 2010). Substance use disorders are linked to criminal behaviour and are a significant burden on the criminal justice system. Approximately 30% of acquisitive crime is committed by individuals supporting drug use with the use of criminal acts (Magura et al., 1995).

Internationally, methadone maintenance has been the primary choice for chronic opioid dependence in prisons and jails, including those in the Netherlands, Australia, Spain and Canada. As a result, it is increasingly implemented in the criminal justice setting (Moller et al., 2007, Stallwitz and Stover, 2007) with the exception of the US which has not generally endorsed the use of methadone treatment. For example, of the 30,000 individuals a year who enter prison or jail nearly 90% of those receiving prescribed methadone are forced to stop or taper off this treatment (Fiscella et al., 2004). Reasons for this lack of expansion suggest that public opinion and that of the criminal justice system providers consider methadone treatment as substituting one addiction for another. In contrast, buprenorphine appears not to carry the same social stigma associated with methadone treatment and has been used in France, Austria and Puerto Rico (Catania, 2003, Garcia et al., 2007, Gordon et al., 2017, Reynaud-Maurupt et al., 2005). This is noted because unlike methadone it can be administered on alternate days, a feature that would make buprenorphine use more efficient in correctional settings than methadone (Garcia et al., 2007). Naltrexone treatment has shown some promising findings, but associated problems surrounding high attrition and low medication compliance in the community and high mortality rates pose concerns (Gibson and Degenhardt, 2007, Minozzi et al., 2011). In 2005 naloxone was added to the UK's

exempt list of prescription-only medicines that could be administered to save life in an emergency to reverse heroin/opioid overdose (Strang et al., 2006). Use of extended-release naltrexone may also be appealing and beneficial to people who are unlikely to access opioid-agonist maintenance treatment or who prefer a relapse-prevention treatment (Lee et al., 2016). Trials conducted in the criminal justice setting are still lacking, and continuity of care is considered crucial in the treatment of drug-using offenders who transition between prison and the community.

A growing body of evidence shows the effects of pharmacological interventions for drug use among the general population (see Table 1 for a summary of the evidence). Existing reviews have focused on naltrexone maintenance treatment for opioid dependence (Amato et al., 2005, Lobmaier et al., 2008, Minozzi et al., 2011), the efficacy of methadone (Faggiano et al., 2003, Marsch, 1998, Mattick et al., 2009) and buprenorphine maintenance (Mattick et al., 2009). Recent guidance has been provided from the National Institute for Health and Clinical Excellence (NICE) on evidence-based use of naltrexone, methadone and buprenorphine for the management of opioid dependence (National Institute for Health and Care Excellence (NICE), 2007a, National Institute for Health and Care Excellence (NICE), 2007b, National Institute for Health and Care Excellence (NICE), 2019). Five Cochrane reviews (including 52 studies) reported on the effectiveness of opiate methadone therapies (Amato et al., 2005). Findings showed that methadone maintenance therapies at appropriate doses were most effective in retaining participants in treatment and in suppressing heroin use, but evidence of effectiveness for other relevant outcome measures such as criminal activity was weak and was not systematically evaluated. Naloxone use is also found to work in a similar manner by blocking the euphoria (reinforcement) sought by the user and thereby reducing the drug-seeking behaviour and diminishing the risk of physical dependence of heroin use (Kurland et al., 1975). Extended-release naltrexone uses the same mechanism as naloxone but gradually releases a sufficient amount to block the euphoria up to 1 month after an injection (Lee et al., 2016).

Systematic reviews evaluating treatment programmes for offender populations have focused on evaluating treatments in one setting such as community-based programmes (Mitchell et al., 2012a, Mitchell et al., 2012b), or have based their evidence on literature from one country (Chanhasilpa et al., 2000, Egg et al., 2000), or a number of specific treatments (Mitchell et al., 2006). Pharmacological systematic reviews of offender treatment appear to be sparse. We identified two previous reviews: one focusing on specific drug- and property-related criminal behaviours in methadone maintenance treatment (Marsch, 1998), and one an evaluation of the effectiveness of opioid maintenance treatment (OMT) in prison and post release (Hedrich et al., 2012). The latter of these two reviews identified six experimental studies up until January 2011 (Hedrich et al., 2012). The authors found that OMT in prison was significantly associated with reduced heroin use, injecting and syringe sharing. The use of pre-release OMT was also found to have important implications for associated treatment uptake after release, but the impact on criminal activity was equivocal. Similar findings have been shown with the use of extended-release naltrexone (XR-NTX) which showed that use of XR-NTX before release might reduce opioid overdose, increase abstinence and antagonist medication coverage during the high-risk initial weeks after release in comparison with referral for XR-NTX treatment in the community after release (Friedmann et al., 2018).

Many people under the care of the criminal justice system have a drug misuse

Table 1 Evidence on pharmacological interventions in the general population

Pharmacological intervention	Effectiveness summary	Administration and dosage	Evidence sources
Methadone maintenance	Methadone is an agonist that activates opioid receptors. Methadone maintenance treatment can keep heroin-dependent people in treatment and help them reduce their use of heroin. It is a heroin replacement treatment. It is typically used with medical supervision because overdose is possible.	Flexible dosage: initial dose 10–30 mg per day, increasing to a maintenance dose of 60–120 mg Single daily dose	Mattick RP, Breen C, Kimber J, Davoli M. Methadone maintenance therapy versus no opioid replacement therapy for opioid dependence. Cochrane Database of Systematic Reviews 2009, Issue 3. Art. No.: CD002209. DOI: https://doi.org/10.1002/14651858.CD002209.pub2 . NIDA. https://www.drugabuse.gov/about-nida/legislative-activities/testimony-to-congress/2017/research-on-the-use-and-misuse-of-fentanyl-and-other-synthetic-opioids-
Buprenorphine	Buprenorphine is a partial agonist that activates opioid receptors but with a diminished response. Buprenorphine is effective in the maintenance treatment of heroin-dependent people, at any dose above 2 mg. It suppresses illicit opioid use (at doses 16 mg or greater). Compared with methadone, buprenorphine retains fewer people when doses are flexibly delivered and at low fixed doses. At fixed medium or higher doses, buprenorphine and methadone are equally effective in terms of retention in treatment and suppression of illicit opioid use. Buprenorphine may be preferred to methadone to avoid unwanted effects such as nausea, vomiting, constipation and drowsiness, mind “clouding” sore leg muscles. Buprenorphine has less overdose potential.	Flexible dosage: Initially 0.8–4 mg for 1 dose on the first day, adjusted in steps of 2–4 mg daily if required; usual dose 12–24 mg daily; maximum 32 mg per day. The drug can be taken once every 2 days.	Mattick RP, Breen C, Kimber J, Davoli M. Buprenorphine maintenance versus placebo or methadone maintenance for opioid dependence. problem (Fazel et al., 2015). Whilst previous research has evaluated treatment programmes for offenders more broadly, we know little about the challenges, treatment and rehabilitation opportunities for offenders with pharmacological interventions aimed at reducing drug use and criminal activity. This includes consideration of when and where to offer treatment along the criminal justice pathway to maximise scarce resources and maximise the effectiveness of treatment. We therefore believe that a systematic review evaluating existing evidence from randomised controlled trials (RCTs) might be helpful in identifying treatments for reducing drug use and criminal activity in this vulnerable population. In principle, the RCT design eliminates the threat to internal validity providing there is a sufficiently large number of units assigned as the experimental and control conditions and methods to reduce bias are implemented (Weisburd, 2010).

Given the importance of relating economic cost to a reduction in drug use and related offending behaviour, good-quality economic evidence will help inform strategies which represent the best use of limited resource (Higgins and Green, 2011). In this review, we use the Drummond checklist (Drummond et al., 2005) to evaluate and document the availability of resource information within the studies. The Drummond checklist is a widely used tool to assess the quality of economic evaluation studies. It assesses whether the study has a well-defined question, describes the competing programmes, provides information on the effectiveness of the programmes, presents all of the important and relevant costs and consequences for each programmes and assesses whether costs and consequences of the programmes were accurately measured and assigned credible values (and discounted appropriately). The checklist also assesses any incremental cost-effectiveness analysis and sensitivity analysis around the costs and consequences.

This systematic review has five primary research questions: (1) Do pharmacological treatments for drug-using offenders reduce drug use? (2) Do pharmacological treatments for drug-using offenders reduce criminal activity? (3) Does the treatment setting (e.g. court, community, prison/secure establishment) affect outcome(s) of pharmacological treatments? (4) Does one type of pharmacological treatment perform better than one other? (5) What are the comparative costs and cost-effectiveness of the available interventions?

The systematic review was guided by a protocol which followed Cochrane approaches (Higgins and Green, 2011) to producing systematic reviews and an earlier version has been published as a Cochrane review (Perry et al., 2015).

Methods

Studies included in the review had to meet a number of different criteria including the study design, the type of participants and type of interventions. Studies had to report pre-specified outcome measures to avoid the possibility of any subsequent bias in choosing outcomes. The eligibility criteria are summarised below and described in detail in Table 2.

Studies of illicit drug-using offenders were included in the review regardless of the gender, age, psychiatric history or ethnicity of the study participants. Eligible interventions were those designed, wholly or in part, to eliminate or prevent relapse to drug use

Table 2 Summary of eligibility criteria

	Inclusion criteria	Exclusion criteria
Population	<ul style="list-style-type: none"> • Illicit drug-using offenders were included in the review regardless of gender, age, psychiatric history, or ethnicity. • Offenders were defined as individuals who were involved in the Criminal Justice System (CJS). • Individuals could reside in special hospitals, prisons, the community or who were diverted from court or placed on arrest referral schemes for treatment. • The study setting could change throughout the process of the study. For example, people involved in the criminal justice system could begin in prison but progress through a work release project into a community setting. • Illicit drug use referred to individuals using drugs occasionally or those who were considered drug dependent. 	<p>Studies where part of the population were not involved in the CJS.</p> <p>Studies where the population were alcohol-using as opposed to drug-using offenders.</p>
Intervention	<ul style="list-style-type: none"> • Eligible interventions were those designed, wholly or in part, to eliminate or prevent relapse to drug use or criminal activity, or both, among participants. We defined relapse as individuals who may have returned to an incarcerated setting, or had subsequently been arrested or had relapsed back into drug misuse, or both. We included a range of different types of interventions in the review. • Experimental interventions included in the review were any pharmacological intervention (e.g. buprenorphine, methadone). • Control interventions eligible for the review were no treatment or waiting list controls or minimal and/or alternative treatment or treatment as usual: Minimal or alternative treatment might include reporting use of a similar intervention but at a less intense level, or using a different theoretical approach but with the same components and/or a different alternative intervention. Treatment as usual included any study that reported a combination and/or component of a (i) psychological based intervention (e.g. anger management, motivational interviewing, counselling, aggression replacement, family therapy), (ii) an educational programme (e.g., health, substance abuse education on risky behaviour) and or (iii) life skills (e.g., financial planning, employment skills, computer skills and interpersonal skills in interviews). 	<p>Studies of alcohol misuse only were not eligible.</p> <p>Studies of interventions with drug-using offenders that were not focused on reducing drug use.</p>

Table 2 (continued)

	Inclusion criteria	Exclusion criteria
Outcomes measures	<ul style="list-style-type: none"> • Primary outcomes were drug use measures (self-reported drug use and biological drug use), self-reported or official report of criminal activity and adverse effects. • Secondary outcomes were resource use, costs and cost-effectiveness related to the interventions, health care activity, criminal activity and productivity. 	
Study design	<ul style="list-style-type: none"> • RCTs were the eligible study design 	Studies that did not report data in a format that allowed us to generate post dichotomous/continuous outcomes
Limits	<ul style="list-style-type: none"> • No date or language limits will be applied to the searches 	

or criminal activity, or both, among participants. We defined relapse as individuals who may have returned to an incarcerated setting, or had subsequently been arrested or had relapsed back into drug misuse, or both. The primary outcomes investigated in the review were drug use (self-reported drug use measures and biological drug use measures), self-reported or official report of criminal activity (dichotomous and continuous data for arrests, reincarceration and parole violations) and adverse effects. Secondary outcomes were resource use, costs and cost-effectiveness related to the interventions, health care activity, criminal activity and productivity. Randomised controlled trials (RCTs) were the eligible study design and no date or language limits were applied to this review.

Search strategy for identification studies

The original searches for this review are reported in Perry (Perry et al., 2006, Perry et al., 2015) and were subsequently updated in January 2018 to cover the period 2014 to 2018 and then updated further again in February 2019 to cover the period 2018 to 2019. We searched 12 databases: ASSIA, CINAHL, Cochrane Central Register of Controlled Trials (CENTRAL), Criminal Justice Abstracts, Embase, Health Management Information Consortium (HMIC), LILACS, MEDLINE, PAIS, PsycINFO, Science Citation Index and Social Science Citation Index. The full search strategies for each database are included in the [Appendix](#).

To identify economic studies the topic specific searches of nine databases (ASSIA, CENTRAL, CINAHL, Criminal Justice Abstracts, HMIC, LILACS, PAIS, Science Citation Index, Social Science Citation Index) would have identified all potential RCTs and economic evaluations included in the review. For the Embase, MEDLINE and PsycINFO databases the search strategy incorporated an RCT filter to manage the number of identified and relevant citations. This approach may have excluded potential economic evaluations identified from these three databases and is therefore a limitation of the review.

We developed individual search strategies for each database and made use of any controlled vocabulary available for each database. We combined the subject search

terms with methodological search filters designed to identify RCTs, where available. Additional search approaches were employed including checking the reference lists of all retrieved articles for further references, searching catalogues of relevant organisations and contacting experts to obtain recommendations of other published or unpublished studies relevant to the review. All references were managed in EndNote (Clarivate, 2020) and subsequently Covidence (Veritas Health Innovation, 2013) software.

Screening and coding process

A team of reviewers independently inspected the titles and abstracts for potential inclusion in the review. Each record was assessed by two reviewers. The full articles were obtained for each record which seemed likely to be eligible and the full text was assessed for eligibility by two reviewers independently. In the case of disagreement, a third independent reviewer helped to arbitrate. The screening criteria are provided in the [Appendix](#).

We used data extraction forms to standardise the reporting of data from all studies obtained as potentially relevant. Two reviewers independently extracted data and subsequently checked them for agreement. The narrative tables included a presentation of the study details (e.g. author, year of publication and country of study origin), study methods (e.g. random assignment), participants (e.g. number in sample, age, gender and ethnicity), interventions (e.g. description, duration, intensity and setting), outcomes (e.g. description, follow-up period and reporting mechanism) and notes (e.g. country and funding).

Measures of treatment effect

Studies were combined as mean differences (MD) with 95% confidence intervals in the meta-analyses for continuous outcomes measured on the same scale and standardised mean difference (SMD) for outcomes measured on different scales. Higher scores for continuous measures are representative of greater harm. We present dichotomous outcomes as risk ratios (RR), with 95% confidence intervals (CIs).

Statistical issues

To avoid double counting of outcome measures (e.g. arrest and parole violation) and follow-up time periods (e.g. 12, 18 months), we checked all trials to ensure that multiple studies reporting the same evaluation did not contribute towards multiple estimates of programme effectiveness. We followed Cochrane guidance and we combined intervention and control groups to create a single pair-wise comparison. Where this was not appropriate we selected one treatment arm and excluded the others. We attempted to contact the study authors via email where missing data occurred in the original publication.

We assessed heterogeneity using the I^2 statistic and Chi^2 statistic (Higgins and Green, 2011). We regarded heterogeneity as substantial if the I^2 was greater than 50% or the p value was lower than 0.10 for the Chi^2 test for heterogeneity (Deeks et al., 2017). Following specific Cochrane guidance (Deeks et al., 2017), we

distinguished the following values to denote no important, moderate, substantial and considerable heterogeneity, respectively: 0 to 40%, 30 to 60%, 50 to 90% and 75 to 100%.

Risk of bias assessment

The review team assessed risk of bias in all included studies using risk of bias assessment criteria recommended in the Cochrane Handbook (Higgins and Green, 2011). Further detail on risk of bias assessment is provided in the [Appendix](#).

Data synthesis

The Revman software package (The Nordic Cochrane Centre (The Cochrane Collaboration), 2014) was used to perform a series of meta-analyses for continuous and dichotomous outcome measures. A random effects model was used to account for participants coming from different underlying populations. We used the transformations as laid down by the Cochrane Handbook (Higgins and Green, 2011) for continuous outcomes. For conversions of standard error into standard deviations and the calculation of standard deviations calculated from 95% confidence intervals (CIs) we used the standard equations set out in Fig. 1.

Economic appraisal

Economic or resource use information was assessed using the Drummond classification scheme (see [Appendix](#)) (Drummond et al., 2005). This criterion was applied by an economist to indicate the costs and the consequences of the intervention(s) relevant to various public sectors. These included healthcare, criminality, labour force participation or other public goods. According to Drummond, studies containing information on the economics of the intervention can be classified as full economic evaluation studies or partial economic evaluation studies (Drummond et al., 2005). A full economic evaluation is a comparative analysis of two or more interventions in terms of both resource

	Group 1 (e.g. males)	Group 2 (e.g. females)	Combined groups
Sample size	N_1	N_2	$N_1 + N_2$
Mean	M_1	M_2	$\frac{N_1M_1 + N_2M_2}{N_1 + N_2}$
SD	SD_1	SD_2	$\sqrt{\frac{(N_1 - 1)SD_1^2 + (N_2 - 1)SD_2^2 + \frac{N_1N_2}{N_1 + N_2}(M_1^2 + M_2^2 - 2M_1M_2)}{N_1 + N_2 - 1}}$

$$SD = SE \times \sqrt{N}$$

$$SD = \sqrt{N} \times (\text{upper limit} - \text{lower limit}) / 3.92$$

Fig. 1 Statistical treatment

use (or costs) and outcomes (or consequences) (Drummond et al., 2005). Full economic evaluations can be further classified as cost-benefit analysis, cost-effectiveness analysis and cost-utility analysis based on consequences measured in monetary units, physical units (e.g. mortality) and utilities (e.g. quality-adjusted life years (QALYs)), respectively. Evaluations that are not comparative or do not consider both costs and consequences are classified as partial evaluations (e.g. cost-outcome description or cost analysis). Studies containing economic information using the Drummond criteria were identified, and information related to resource use and perspectives were recorded.

Search results

Searches for this review were first conducted in Perry (Perry et al., 2006, Perry et al., 2015) and were last updated in February 2019. The searches identified a total of 16,786 records and 988 additional records were identified from other sources. Following deduplication, 9657 records were screened using information in the title and abstract. Of these, 9406 records were excluded. We acquired the remaining 251 full papers for assessment and excluded 237 of these. A total of 22 studies were finally deemed eligible for the review and were included in the qualitative synthesis, with 19 of them included in the meta-analyses. The 22 included studies randomised 4372 participants from research published between 1969 and 2019. Fig. 2 shows the PRISMA flow diagram of the numbers of records included and excluded at each stage of the selection process.

Fourteen of the 22 trials were conducted in the US and three in the UK. The other 5 studies were conducted in Iran, Australia, Norway, Sweden and Mexico. Twenty-one of the 22 studies included male adult drug-using offenders and 1 study recruited only female participants (Cropsey et al., 2011). In 2 studies, the percentage of each gender was not reported (Kurland et al., 1975, Wright et al., 2011).

The age of study participants ranged from 17 to 55 years. In 7/22 (32%) studies, the majority of participants were of white ethnic origin. The studies were divided by setting into community ($n = 9$) (Brodie et al., 2009, Brown et al., 2013, Cornish et al., 1997, Coviello et al., 2010, Cropsey et al., 2011, Hanlon et al., 1975, Hanlon et al., 1977, Kurland et al., 1975, Lee et al., 2016), prison ($n = 7$) (Bayanzadeh, 2004, Dolan et al., 2003, Dole et al., 1969, Howells et al., 2002, Lobmaier et al., 2010, Rich et al., 2015, Wright et al., 2011) and those that started in a secure setting and continued into the community ($n = 6$) (Kinlock et al., 2005, Kinlock et al., 2007, Konstenius et al., 2014, Magura et al., 2009, McKenzie et al., 2012, Parmar et al., 2017).

Fifteen of the 22 trials evaluated outcomes at 6 months or less, 4 trials reported outcomes up to 12 months (Brown et al., 2013, Dole et al., 1969, Kinlock et al., 2007), 1 study reported outcomes at 18 months (Lee et al., 2015) and 1 reported outcomes at 4 years (Dolan et al., 2003).

Different outcome measures were presented for each study, and just over half of all studies reported 4 or more outcome measures. One study reported on criminal activity only (Cornish et al., 1997) and 8 trials reported on drug use only (Bayanzadeh, 2004, Brown et al., 2013, Cropsey et al., 2011, Dolan et al., 2003, Hanlon et al., 1977, Konstenius et al., 2014, Wright et al., 2011). Six studies did not report any information on adverse events, side effects from the drug or drug safety (Bayanzadeh, 2004, Dolan et al., 2003, Dole et al., 1969, Hanlon et al., 1975, Hanlon et al., 1977, Kurland et al.,

Fig. 2 PRISMA flow diagram

1975). Three studies referred to the measurement of adverse events but did not report them (Coviello et al., 2010, Cropsey et al., 2011, Wright et al., 2011). 4 studies reported resource and cost information (Magura et al., 2009, Murphy et al., 2017, Rich et al., 2015, Warren et al., 2006).

Overview of studies

Meta-analyses

Nineteen of the 22 studies provided data to potentially be included in 1 or more meta-analyses. The interventions report on agonistic pharmacological interventions (buprenorphine, methadone) and antagonistic pharmacological interventions (naltrexone and naloxone) compared with no intervention, other non-pharmacological treatments (e.g. counselling) and other pharmacological drugs (vigabatrin and cyclazocine). The comparisons are shown in Table 3 and in Fig. 3.

Agonist (methadone) versus no intervention (placebo or waiting list control)

Two studies (237 participants) (Cropsey et al., 2011, Dolan et al., 2003) showed no significant reduction in drug use using biological measures (RR 0.74, 95% CI 0.53 to

Table 3 Meta-analysis results by comparison and outcome

Intervention comparison and outcome(s)	Studies (author/year)	Number of participants	Effect size (RR/SMD/MD)	95% CI	<i>P</i> value
Agonist (methadone) vs no intervention (placebo or waiting list control)					
Drug use (objective)	Cropsey et al. 2011 Dolan et al. 2003	237	RR: 0.72	0.51, 1.00	0.05

Drug use (objective)—opioids	Coviello et al. 2010 Lee et al. 2016	371	RR: 0.60	0.44, 0.81	0.0
Drug use (objective)—cocaine	Coviello et al. 2010 Lee et al. 2016	391	RR: 1.47	0.67, 3.23	0.33
Mixed antagonist and agonist (cyclazocine) vs antagonist (naloxone)					
Abstinent at 6 months	Hanlon et al. 1975	70	RR: 1.14	0.46, 2.81	0.77
Agonist (methadone) vs forced tapered withdrawal from methadone					
Drug use and reincarceration 1 month post release	Rich et al. 2015	1078	RR: 0.86	0.63, 1.17	0.23
Any other drug use at 1 month post release	Rich et al. 2015	283	RR: 1.05	0.83, 1.34	0.68
Reincarceration at 1 month post release	Rich et al. 2015	229	RR: 0.92	0.39, 2.16	0.85
Opioid use at 1 month post release	Rich et al. 2015	283	RR: 0.56	0.26, 1.22	0.14
Use of injectable illegal drug	Rich et al. 2015	283	RR: 0.67	0.40, 1.15	0.15
Agonist (methadone) prior to release with financial support vs agonist (methadone) on release with no financial support					
Drug use (heroin) in past 30 days	McKenzie et al. 2012	61	RR: 0.53	0.22, 1.25	0.14
Drug use (other opiates) in past 30 days (dichotomous)	McKenzie et al. 2012	61	RR: 0.14	0.01, 2.57	0.18
Drug use (crack/cocaine) in past 30 days (dichotomous)	McKenzie et al. 2012	61	RR: 0.53	0.22, 1.25	0.14
Drug use (marijuana) in past 30 days (dichotomous)	McKenzie et al. 2012	61	RR: 0.48	0.10, 2.45	0.38
Drug use (polydrug) in past 30 days (dichotomous)	McKenzie et al. 2012	61	RR: 0.81	0.41, 1.58	0.53
Any drug injecting in the past 30 days	McKenzie et al. 2012	61	RR: 0.36	0.11, 1.24	0.11
Criminal justice outcomes	McKenzie et al. 2012	122	RR: 1.04	0.38, 2.81	0.94
Reincarceration (prison/jail/other)	McKenzie et al. 2012	61	RR: 0.48	0.10, 2.45	0.38
Arrested in past 6 months	McKenzie et al. 2012	61	RR: 1.45	0.59, 3.58	0.42

CI confidence interval, *RR* risk ratio, *SMD* standardised mean difference, *MD* mean difference

1.02) and three studies (317 participants) showed no significant reduction in self-reported drug use (RR 0.61, 95% CI 0.31 to 1.18) (Cropsey et al., 2011, Dolan et al., 2003, Dole et al., 1969). Two studies (304 participants) showed a significant reduction in self-reported drug use (SMD -0.57 , 95% CI -0.80 to -0.34) (Dolan et al., 2003, Kinlock et al., 2005). For criminal activity, one study (62 participants) showed no significant reduction in re-arrests (RR 0.60, 95% CI 0.32 to 1.14) (Kinlock et al., 2005). Three studies (472 participants) showed no significant reduction in reincarceration (RR 0.77, 95% CI 0.36 to 1.64) (Dolan et al., 2003, Dole et al., 1969, Kinlock et al., 2005) and one study (51 participants) showed a significant reduction in criminal activity (MD -74.21 , 95% CI -133.53 to -14.89) (Kinlock et al., 2005).

Agonist (methadone) versus partial agonist (buprenorphine)

Two studies (370 participants) showed no significant reduction in self-reported drug use (RR 1.04, 95% CI 0.69 to 1.55) (Magura et al., 2009, Wright et al., 2011). One study (81 participants) showed no significant reduction in self-reported drug use (MD 0.70, 95% CI -5.33 to 6.73) (Magura et al., 2009). One study (116 participants) showed no significant reduction in criminal activity (RR 1.25, 95% CI 0.83 to 1.88) (Magura et al., 2009).

Agonist (methadone) versus antagonist (naltrexone)

A single study (44 participants) showed no significant reduction in self-reported drug use (MD 4.60, 95% CI -3.54 to 12.74) and showed no significant reduction in dichotomous (RR 1.10, 95% CI 0.37 to 3.26) or continuous measures of reincarceration (MD -0.50 , 95% CI -8.04 to 7.04) (Lobmaier et al., 2010).

Agonist (methadone) and non-pharmacological intervention versus non-pharmacological intervention

Two studies (203 participants) showed no significant reduction in self-reported drug use (RR 0.39, 95% CI 0.14 to 1.13) (Bayanzadeh, 2004, Kinlock et al., 2007).

Agonist (vigabatrin) versus placebo

One study (103 participants) showed no evidence of a difference in terms of the number of negative urine tests for cocaine (MD 2.1, 95% CI -0.34 to 4.54) and end of trial abstinence for marijuana (RR 0.64, 95% CI 0.16 to 2.52) but showed evidence of a difference in the end of trial abstinence (RR 1.06, 95% CI 0.28 to 4.01) and 4-week abstinence for cocaine (RR 6.36, 95% CI 1.50 to 27.01) (Bayanzadeh, 2004, Brodie et al., 2009, Kinlock et al., 2007).

Antagonist (naloxone) versus no intervention (placebo or waiting list control)

Three studies (333 participants) showed no significant reduction in self-reported drug use (RR 1.06, 95% CI 0.87 to 1.28) (Hanlon et al., 1975, Hanlon et al., 1977, Parmar et al., 2017).

Fig. 3 Forest plots of intervention effects

Antagonist (naltrexone) versus non-pharmacological treatment

Two studies (371 participants) showed a significant reduction in subsequent opioid use (RR 0.60, 95% CI 0.44 to 0.81) (Coviello et al., 2010, Lee et al., 2016). Two studies

Fig. 3 continued.

(371 participants) showed no significant reduction in cocaine use (RR 1.24, 95% CI 0.54 to 2.84) (Coviello et al., 2010, Lee et al., 2016). Three studies (422 participants) showed a significant reduction in subsequent reincarceration (RR 0.55, 95% CI 0.31 to 0.99) (Cornish et al., 1997, Coviello et al., 2010, Lee et al., 2016). One study (63 participants) showed no significant reduction in subsequent drug charges (RR 3.10, 95% CI 0.34 to 28.19) (Coviello et al., 2010).

Mixed antagonist and agonist (cyclazocine) versus antagonist (naloxone)

One study (70 participants) showed no significant reduction in abstinence at 6 months comparing mixed antagonist and agonist (cyclazocine) with the antagonist naloxone (RR 1.14, 95% CI 0.46 to 2.81) (Hanlon et al., 1975).

Agonist (methadone) versus forced tapered withdrawal from methadone

One study (283 participants) explored continued use of methadone within a prison setting compared with forced tapered withdrawal of methadone (Rich et al., 2015). The study found no significant difference in reduction in any drug use at 1 month following release from prison (RR 1.05, 95% CI 0.83 to 1.34), opioid use at 1 month following release (RR 0.56, 95% CI 0.26 to 1.22) or use of injectable illegal drugs (RR 0.67, 95% CI 0.40 to 1.15) (Rich et al., 2015). The study also found no difference between the two options in terms of reincarceration at 1 month post release from prison (RR 1.49, 95% CI 0.63 to 3.53) (Rich et al., 2015).

Agonist (methadone) prior to release with financial support versus agonist (methadone) on release with no financial support

One study (46 participants) explored the impact of providing financial support for methadone treatment following release from prison compared with no financial support on drug outcomes and criminal justice outcomes (McKenzie et al., 2012). The study found no significant difference between the two options in terms of heroin use in the past 30 days (RR 0.46, 96% CI 0.20 to 1.03), use of other opiates in the past 30 days (RR 0.12, 95% CI 0.01 to 2.22), use of crack/cocaine in the past 30 days (RR 0.46, 95% CI 0.20 to 1.03), marijuana use in the past 30 days (RR 0.42, 95% CI 0.09 to 2.07), polydrug use in the past 30 days (RR 0.70, 95% CI 0.38 to 1.28) or any drug injecting in the past 30 days (RR 0.32, 95% CI 0.10 to 1.04) (McKenzie et al., 2012). The study reported no significant difference between the interventions for reincarceration (RR 0.42, 95% CI 0.09, 2.07) or arrest within the past 6 months (RR 1.26, 95% CI 0.54, 2.96) (McKenzie et al., 2012).

Narrative findings

Narrative findings were presented for three studies where suitable data for extraction and exclusion in the meta-analysis were not available. One study compared methylphenidate or placebo to a non-pharmacological intervention (Konstenius et al., 2014). In this study, male participants with attention deficit disorder receiving methylphenidate had a higher proportion of drug negative urine test results compared with the placebo group ($p = 0.047$). A second study compared a specialist facility for treatment of methadone versus primary care plus suboxone (buprenorphine and naloxone) versus a specialist facility for suboxone treatment (Brown et al., 2013). At 6 months, the authors reported no use of opioids in any of the randomised groups (total of 15 participants). The final study compared methadone and placebo versus lofexidine and placebo (Howells et al., 2002). The authors reported no statistical reduction in the amount ($p = 0.36$) or intensity ($p = 0.46$) of opioid (heroin) use in the last month.

Adverse events

Seven of the 22 (32%) studies did not report any information on adverse events, side effects of drugs nor referred to drug safety (Bayanzadeh, 2004, Brown et al., 2013, Dolan et al., 2003, Dole et al., 1969, Hanlon et al., 1975, Hanlon et al., 1977, Kurland

et al., 1975). Three (3/22, 14%) studies measured adverse events, but did not report the findings (Coviello et al., 2010, Cropsey et al., 2011, Wright et al., 2011). Forty-one percent of the studies (9/22) reported only mild or moderate adverse events (Brodie et al., 2009, Cornish et al., 1997, Howells et al., 2002, Kinlock et al., 2005, Konstenius et al., 2014, Lee et al., 2016, Lobmaier et al., 2010, Magura et al., 2009, Parmar et al., 2017). One study reported 10 serious adverse events including nine hospitalisations (Kinlock et al., 2007). The hospitalisations included two cases for heart disease and one each for pneumonia, alcohol detoxification, kidney disease, high blood pressure, psychiatric problems and back pain (Kinlock et al., 2007). Two studies reported a fatal overdose (Kinlock et al., 2007, Rich et al., 2015) and one study reported two fatal overdoses (McKenzie et al., 2012).

Economic outcomes

The economic appraisal using the Drummond criteria identified four studies reporting some cost information (Magura et al., 2009, Murphy et al., 2017, Rich et al., 2015, Warren et al., 2006). Table 4 shows the results of the type of resource costs described for each paper. Three of the four studies were full economic evaluations reporting both incremental costs and outcomes (Magura et al., 2009, Murphy et al., 2017, Warren et al., 2006).

In terms of the overall Drummond classification (Drummond et al., 2005), three studies were coded as 4 (a full economic evaluation) and one study was coded as 3 (partial economic evaluation).

The Magura 2009 (Magura et al., 2009) study noted differences in the costs of administering buprenorphine and methadone, but were not sufficient for us to conduct a full cost-effectiveness appraisal. The investigators estimated that about ten times as many inmates can be served with methadone as with buprenorphine with the same staff resources. This cost implication is also endorsed in the community, where physicians have difficulty in obtaining reimbursement for buprenorphine treatment for released inmates, making the continued use of buprenorphine problematic after release.

The Murphy 2017 (Murphy et al., 2017) study conducted a full economic analysis reporting incremental cost-effectiveness ratios (ICERs), costs, QALYs and abstinent years of using extended-release naltrexone (XR-NTX) compared with treatment as usual (TAU) at 25 weeks and 78 weeks, respectively. The 25-week ICERs were reported as \$162,150/QALY and \$46,329/abstinent year. The ICER values at 78 weeks were \$76,400/QALY and \$16,371/abstinent year. The study reported that XR-NTX was effective in increasing both QALYs and abstinence rates compared with TAU. However, it was not cost-effective at the normally accepted threshold levels in the US, primarily due to the high price of the injection.

The Warren 2006 (Warren et al., 2006) study estimated the cost-effectiveness of the New South Wales (NSW) prison methadone programme compared with no methadone program. The study reported the annual cost of providing prison methadone in NSW as AUD\$2.9million (or AUD\$3234 per inmate per year) and the ICER as AUD \$38 per additional heroin-free day. It also reported that prison methadone is not costlier than community methadone, and it reduces morbidity and mortality through decreasing heroin use in prisons.

Table 4 Available economic information (resource use and/or cost) and evaluation type according to Drummond classification scheme (see [Appendix](#))

Study	Sample description	Location/ country	Perspective	Intervention	Does the study describe resource use and/or costs for				Drummond score
					Interventions	Healthcare	Criminality	Productivity	
Magura et al. 2009 [68]	Inmates aged 18–65 years eligible for Key Extended Entry Program (KEEP)	New York City, USA	Not reported	Methadone and buprenorphine	✓	✓	–	–	3 (cost analysis)
Murphy et al. 2017 [72]	Participants aged 18–60 years diagnosed with opioid dependence and serving an adjudicated sentence under supervision	US		Northeast corridor	US taxpayer				
	Extended-release naltrexone vs treatment as usual (cost-effectiveness and cost-utility analysis)	✓	✓	✓	–	4			
		Warren et al. 2006 [73]	Prisoners in a New South Wales (NSW)	programme	Australia	Treatment		provider/ funder	Prison methadone programme
✓	✓	–	–	4					
	(cost-effectiveness analysis)	Rich et al. 2015 [64]	Adult male and female	prisoners in a combined prison and jail	Rhode Island, USA	Healthcare payer	Prison		methadone programme
✓	✓	–	–	4					
	(cost-effectiveness analysis)								

The final study by Rich 2015 (Rich et al., 2015) reported, as a secondary outcome, on healthcare costs (per inmate) associated with continued methadone maintenance-treatment programme compared with usual care (i.e. forced withdrawal from methadone) at 1 month after release from incarceration. Continued methadone treatment resulted in higher (methadone) treatment cost per individual compared with forced withdrawal (\$362 vs \$225, $p < 0.001$). The additional treatment costs were offset by savings incurred by reduced cost for physician (\$6.60 vs \$8.80, $p = 0.793$) and medical care (\$211 vs \$372, $p = 0.894$) after release, resulting in lower total costs (\$609 vs \$637, $p < 0.001$). Continued methadone treatment also resulted in a greater probability of attendance at a methadone clinic after release and was more effective than forced withdrawal.

Risk of bias assessment

Although all the included studies were randomised trials, the level of reporting was uneven and many had unclear or high risk of bias for at least one element of the risk of bias assessment. Nearly 50% were rated as unclear risk of bias in terms of random sequence generation and over 50% of the trials were rated as unclear in terms of allocation concealment. 32% (7/22) of the studies were rated as low risk of bias for participant and personnel blinding and 82% (18/22) were rated as unclear on both subjective and objective measures of detection bias. Over 75% of the trials were at high risk of bias because they did not report all of the outcome data they set out to collect.

Fig. 4 Risk of bias judgements

Over 50% of the studies were rated at low risk for selective reporting. The overall risk of bias judgements of the included studies are shown in Fig. 4, and summary and detailed accounts of the risk of bias assessment can be found in the [Appendix](#).

Conclusions

The results of this systematic review provide some evidence to answer our original review questions. The review identified that we have some evidence to suggest that pharmacological interventions are effective in reducing drug use and criminal activity (Perry et al., 2015). The updated review revealed a total of 22 trials involving 4372 participants. The 22 trials compared pharmacological interventions or compared pharmacological interventions to no intervention and/or a placebo. Most studies were conducted in the USA, with the majority involving male adult offenders. The updated meta-analyses included 19/22 quantitative studies. Ten different pharmacological drugs were evaluated including methadone, buprenorphine, naltrexone, methylphenidate, vigabatrin, suboxone, naloxone, lofexifine, naltrexone and cyclazocine. Methadone in comparison with no treatment was the only comparison to demonstrate a significant reduction in subsequent drug use (using biological measures), self-reported drug use (using continuous measures) and criminal activity. When compared with methadone, no significant differences were found for buprenorphine, naltrexone or suboxone. None of these studies identified a significant reduction in either criminal activity and/or drug use. One study comparing buprenorphine to placebo (Cropsey et al., 2011) was the only study to involve wholly female offenders. More pharmacological trials of female offenders are required to identify comparability between men and women.

Studies of naloxone and methylphenidate in comparison with a placebo and non-pharmacological intervention, respectively, showed no significant differences for self-reported drug use. The evidence supporting the use of naloxone was explored using two very old studies (Hanlon et al., 1977, Hanlon et al., 1975) and one more recent study that had to be halted early due to problems with the randomisation procedure (Parmar et al., 2017). Naltrexone in comparison with a non-pharmacological intervention showed a significant reduction in self-reported drug use and reincarceration. The use of extended naltrexone pre and post prison release has produced some promising results, finding no overdoses during the treatment process (Lee et al., 2016). This study also reported that use of extended-release naltrexone was associated with a rate of opioid relapse that was lower than that with usual treatment at 24 weeks, but later comparisons (at 52 and 78 weeks) found no difference between the use of extended-release naltrexone and use of a brief counselling intervention (Lee et al., 2016). One study investigated methadone continuation treatment compared with forced tapered withdrawal from methadone within a prison setting, but found no significant difference in the reduction of any drug use at 1 month following release (Rich et al., 2015). The study also found no difference between the treatment options where reincarceration occurred at 1 month post release from prison. The impact of providing financial support for methadone treatment following release from prison was compared with no financial support in one study, but no significant difference was observed in terms of drug use or criminal justice outcomes (McKenzie et al., 2012). The study also reported no significant difference between the interventions in relation to arrest or reincarceration at six-

month follow-up. We were unable to answer our third review questions about the impact of treatment setting on drug use or criminal activity. This was primarily because of the heterogeneity of the study comparisons and outcome measures. Given the relatively scarce resources for drug treatment evaluation opportunities in this population, future research should seek to build on existing trial data to develop an evidence-base to allow for such comparisons to be made.

The majority of studies included in the review reported only mild to moderate adverse effects, or did not report on drug safety as part of the trial information. One study reported serious adverse effects and three studies reported overdoses. Adverse effects should be measured consistently across any pharmacological drug trial to capture important data about drug safety. The current evidence does not provide a comprehensive overview of drug safety within this population.

Our final review question focused on the comparative costs and cost-effectiveness evidence of using such interventions to reduce drug use and criminal activity. An appraisal of the economic evidence identified studies with costs and outcomes data for pharmacological treatments among drug-using offenders in three studies and costs data in one study. All studies reported data on the direct medical costs associated with the provision of treatment (Magura et al., 2009, Murphy et al., 2017, Rich et al., 2015, Warren et al., 2006) and one study also included costs related to criminal justice (Murphy et al., 2017). The findings from the studies revealed the higher effectiveness of pharmacological treatments in terms of increased QALYs and abstinent years (Murphy et al., 2017) and reduced heroin use (Warren et al., 2006). One study reported methadone to be cost-effective at the current willingness to pay thresholds (Warren et al., 2006). Another study reported continued methadone treatment to dominate forced withdrawal in terms of costs and effects (Rich et al., 2015). More research is needed to compare the relative cost-effectiveness of a range of treatments (pharmacotherapies, non-pharmacological interventions and combined treatments) in prison and community-based criminal justice settings.

Additionally, the studies contained mainly male offenders, with only one study containing a 100% sample of female offenders. The majority of studies were conducted in the USA. Together these factors limit the external validity and generalisability of the study findings. For these reasons, the studies are unlikely to reflect different international practice in the criminal justice system. Besides the limitations already discussed, the search methodology was limited to databases that could be accessed via the University of York and extensive website searches were not conducted. As a result, some literature may have been missed from this updated version. Specific search terms were not used to identify cost and cost-effectiveness studies in 3/12 databases which meant that some economic studies might have been missed from this review.

Several research implications can be identified from this review. Generally, better quality research is required to evaluate the effectiveness of interventions with extended long-term effects of aftercare following release into the community. Buprenorphine research in the prison environment requires evidence of the long-term impact and larger studies; currently, an equivalence of buprenorphine and methadone exists. Future clinical trials should collect information from all sectors of the criminal justice system. This would enhance the heterogeneous nature of the included studies and would facilitate generalisation of study findings. Evidence of comparable mortality rates in prisoners using pharmacological interventions (particularly after release) needs to be

explored to assess the long-term outcomes of such treatments, perhaps using alternative study designs to randomised controlled trials. The link between dosage, treatment retention and subsequent criminal activity should be examined across all three pharmacological treatment options. Evidence from other trial data suggests that dose has important implications for retention in treatment; in future studies, this should be considered alongside criminal activity outcomes. Cost and cost-effectiveness information should be standardised within trial evaluations; this will help policymakers to decide upon health versus criminal justice costs.

Acknowledgements We would like to acknowledge the help of the York Health Economics Consortium (YHEC), the Department of Health Sciences at the University of York and the Cochrane Drugs and Alcohol Group.

Author contributions Amanda E. Perry, Caroline Pearson, Aboaja Anne, Thakkar Pratish, Santosh Kumar, Lucy Burns, Marrison Martyn-St James and Julie Glanville all contributed to the screening of abstracts for inclusion and extraction of data for the final report. Kath Wright conducted and advised on the updated search strategies. Matthew Bunney supported the presentation and summary of data for the report. Catherine Hewitt provided statistical expertise on the meta-analyses and Shilpi Swarmi conducted the appraisal of economic evidence.

Compliance with ethical standards

Conflict of interest The authors declare that they have no conflict of interest.

Appendix

1. Search Strategy

The searches for this updated review were conducted in February 2019 in the following databases:

ASSIA, CENTRAL, CINAHL, Criminal Justice Abstracts, Embase, HMIC, LILACS, MEDLINE, PAIS, PsycINFO, Science Citation Index, Social Science Citation Index.

Initially, there were 4384 records identified. After deduplication, there were 2603 records remaining. After further deduplication against the results of the January 2018 update search, 2445 records remained.

1.1 ASSIA search strategy

Social Science Citation Index via Web of Science search strategy (search date = 6th February 2019, 757 records, Indexes = SSCI Timespan = 1900–2019)

1TOPIC:

(substance* NEAR/2 (addict* or depend* or disorder* or abuse* or abusing or misuse* or misusing or consumption* or withdraw* or withdraw* or detox*)) OR TOPIC: (drug* NEAR/2 (addict* or depend* or disorder* or abuse* or abusing or misuse* or misusing or consumption* or withdraw* or withdraw* or detox*)) OR TOPIC: (narcotic* NEAR/2 (addict* or depend* or disorder* or abuse* or abusing or misuse* or misusing or consumption* or withdraw* or withdraw* or detox*))

2TOPIC: (mdma or alcohol* or opiate* or opioid* or opium or heroin or methadone or cocaine or amphetamine* or marijuana or cannabis or crack or phencyclidine)

3#2 OR #1

4TOPIC: ("justice system" or remand* or parole* or probation or court* or corrections or correctional or revocation) OR TOPIC: (crime or criminal or offender* or criminal* or convict* or felon*) OR TOPIC: (custody or custodial or gaol* or jail* or prison* or incarcerat* or inmate*) OR TOPIC: (reoffend* or reincarcerat* or recidiv* or ex-offender*)

#5#4 AND #3

2. Screening criteria

The screening process was divided into two key phases. Phase one used seven key questions reported in the original new reference review:

Prescreening criteria: phase one

Is the document an empirical study? [If "no" exclude document.]

Does the study evaluate an intervention, a component of which is designed to reduce, eliminate or prevent relapse among drug-using offenders?

Are the participants referred by the criminal justice system at baseline?

Does the study report pre-programme and post-programme measures of drug use?

Does the study report pre-programme and post-programme measures of criminal behaviour?

Is the study a randomised controlled trial?

Do the outcome measures refer to the same length of follow-up for two groups?

Papers included after phase one screening were then scrutinised to assess:

Prescreening: phase two

Is the intervention a pharmacological intervention? [if "yes" include document]

3. Drummond (1996) checklist—risk of bias assessment tool for economic evaluations

Study question	Study name	Grade (yes/no/not clear/N/A)	Comments
Study design			
1. Was the research question stated?			
2. Was the economic importance of the research question stated?			
3. Was/were the viewpoint(s) of the analysis clearly stated and justified?			
4. Was a rationale reported for the choice of the alternative programmes or interventions compared?			
5. Were the alternatives being compared clearly described?			
6. Was the form of economic evaluation stated?			
7. Was the choice of form of economic evaluation justified in relation to the questions addressed?			
Data collection			
8. Was/were the source(s) of effectiveness estimates used stated?			
9. Were details of the design and results of the effectiveness study given (if based on a single study)?			
10. Were details of the methods of synthesis or meta-analysis of estimates given (if based on an overview of a number of effectiveness studies)?			
11. Were the primary outcome measure(s) for the economic evaluation clearly stated?			
12. Were the methods used to value health states and other benefits stated?			
13. Were the details of the subjects from whom valuations were obtained given?			
14. Were productivity changes (if included) reported separately?			
15. Was the relevance of productivity changes to the study question discussed?			
16. Were quantities of resources reported separately from their unit cost?			
17. Were the methods for the estimation of quantities and unit costs described?			
18. Were currency and price data recorded?			
19. Were details of price adjustments for inflation or currency conversion given?			
20. Were details of any model used given?			
21. Was there a justification for the choice of model used and the key parameters on which it was based?			
Analysis and interpretation of results			
22. Was the time horizon of cost and benefits stated?			
23. Was the discount rate stated?			
24. Was the choice of rate justified?			
25. Was an explanation given if cost or benefits were not discounted?			

26. Were the details of statistical test(s) and confidence intervals given for stochastic data?
27. Was the approach to sensitivity analysis described?
28. Was the choice of variables for sensitivity analysis justified?
29. Were the ranges over which the parameters were varied stated?
30. Were relevant alternatives compared? (That is, were appropriate comparisons made when conducting the incremental analysis?)
31. Was an incremental analysis reported?
32. Were major outcomes presented in a disaggregated as well as aggregated form?
33. Was the answer to the study question given?
34. Did conclusions follow from the data reported?
35. Were conclusions accompanied by the appropriate caveats?
36. Were generalisability issues addressed?

Adapted from Drummond MF, Jefferson TO (1996) Guidelines for authors and peer reviewers of economic submissions to the BMJ. The BMJ Economic Evaluation Working Party. British Medical Journal 313 (7052): 275–83. Cited in Centre for Reviews and Dissemination (2008) Systematic reviews. CRD's guidance for undertaking reviews in health care. York: Centre for Reviews and Dissemination

4. Drummond (2005) classification scheme for economic evaluations

Are both costs (inputs) and consequences (outputs) of the alternative examined?			
Are two or more alternatives compared?	No	No	Yes
	Examine consequences only	Examine costs only	
	PARTIAL EVALUATION		PARTIAL EVALUATION
	Outcome description (1A)	Cost description (1B)	Cost-outcome description (2)
Yes	PARTIAL EVALUATION		FULL ECONOMIC EVALUATION (4)
	Efficacy effectiveness evaluation (e.g. RCT) (3A)	Cost analysis (3B)	Cost-effectiveness analysis Cost-utility analysis Cost-benefit analysis

5. Risk of bias assessments of randomised controlled trials—criteria for judging risk of bias assessments

Item	Judgement	Description
1. Random sequence generation (selection bias)	Low risk	The investigators describe a random component in the sequence generation process such as random number table; computer random number generator; coin tossing; shuffling cards or envelopes; throwing dice; drawing of lots; minimisation.
	High risk	The investigators describe a non-random component in the sequence generation process such as odd or even date of birth; date (or day) of admission; hospital or clinic record number; alternation; judgement of the clinician; results of a laboratory test or a series of tests; availability of the intervention.
	Unclear risk	Insufficient information about the sequence generation process to permit judgement of low or high risk.
2. Allocation concealment (selection bias)	Low risk	Investigators enrolling participants could not foresee assignment because one of the following, or an equivalent method, was used to conceal allocation: central allocation (including telephone, web-based, and pharmacy-controlled randomisation); sequentially numbered drug containers of identical appearance; sequentially numbered, opaque, sealed envelopes.
	High risk	Investigators enrolling participants could possibly foresee assignments because one of the following method was used: open random allocation schedule (e.g. a list of random numbers); assignment envelopes without appropriate safeguards (e.g. if envelopes were unsealed or non-opaque or not sequentially numbered); alternation or rotation; date of birth; case record number; any other explicitly unconcealed procedure.
	Unclear risk	Insufficient information to permit judgement of low or high risk. This is usually the case if the method of concealment is not described or not described in sufficient detail to allow a definite judgement.
3. Blinding of participants and providers (performance bias) Objective outcomes	Low risk	No blinding or incomplete blinding, but the review authors judge that the outcome is not likely to be influenced by lack of blinding; blinding of participants and key study personnel ensured, and unlikely that the blinding could have been broken.
	High risk	No blinding or incomplete blinding, and the outcome is likely to be influenced by lack of

		blinding; blinding of key study participants and personnel attempted, but likely that the blinding could have been broken, and the outcome is likely to be influenced by lack of blinding.
	Unclear risk	Insufficient information to permit judgement of low or high risk; the study did not address this outcome.
4. Blinding of participants and providers (performance bias)—subjective outcomes	Low risk	Blinding of participants and providers and unlikely that the blinding could have been broken;
	High risk	No blinding or incomplete blinding, and the outcome is likely to be influenced by lack of blinding; blinding of key study participants and personnel attempted, but likely that the blinding could have been broken, and the outcome is likely to be influenced by lack of blinding.
	Unclear risk	Insufficient information to permit judgement of low or high risk; the study did not address this outcome.
5. Blinding of outcome assessor (detection bias)—objective outcomes	Low risk	No blinding of outcome assessment, but the review authors judge that the outcome measurement is not likely to be influenced by lack of blinding; blinding of outcome assessment ensured, and unlikely that the blinding could have been broken.
	High risk	No blinding or incomplete blinding, and the outcome is likely to be influenced by lack of blinding; blinding of key study participants and personnel attempted, but likely that the blinding could have been broken, and the outcome is likely to be influenced by lack of blinding.
	Unclear risk	Insufficient information to permit judgement of low or high risk; the study did not address this outcome.
6. Blinding of outcome assessor (detection bias)—subjective outcomes	Low risk	No blinding of outcome assessment, but the review authors judge that the outcome measurement is not likely to be influenced by lack of blinding; blinding of outcome assessment ensured, and unlikely that the blinding could have been broken.
	High risk	No blinding of outcome assessment, and the outcome measurement is likely to be influenced by lack of blinding; blinding of outcome assessment, but likely that the blinding could have been broken, and the outcome measurement is likely to be influenced by lack of blinding.
	Unclear risk	Insufficient information to permit judgement of low or high risk.
	Low risk	No missing outcome data; reasons for missing outcome data unlikely to be related to true

7. Incomplete outcome data (attrition bias)—
for all outcomes except retention in
treatment or drop out

outcome (for survival data, censoring unlikely to be introducing bias); missing outcome data balanced in numbers across intervention groups, with similar reasons for missing data across groups; for dichotomous outcome data, the proportion of missing outcomes compared with observed event risk not enough to have a clinically relevant impact on the intervention effect estimate; for continuous outcome data, plausible effect size (difference in means or standardised difference in means) among missing outcomes not enough to have a clinically relevant impact on observed effect size; missing data have been imputed using appropriate methods; all randomised patients are reported/analysed in the group they were allocated to by randomisation irrespective of non-compliance and co-interventions (intention to treat)

High risk Reason for missing outcome data likely to be related to true outcome, with either imbalance in numbers or reasons for missing data across intervention groups;
for dichotomous outcome data, the proportion of missing outcomes compared with observed event risk enough to induce clinically relevant bias in intervention effect estimate; for continuous outcome data, plausible effect size (difference in means or standardised difference in means) among missing outcomes enough to induce clinically relevant bias in observed effect size; “As-treated” analysis done with substantial departure of the intervention received from that assigned at randomisation.

Unclear risk Insufficient information to permit judgement of low or high risk (e.g. number randomised not stated, no reasons for missing data provided; number of drop out not reported for each group).

8. Selective reporting (reporting bias)

Low risk The study protocol is available and all of the study’s pre-specified (primary and secondary) outcomes that are of interest in the review have been reported in the pre-specified way; the study protocol is not available but it is clear that the published reports include all expected outcomes, including those that were pre-specified (convincing text of this nature may be uncommon).

High risk Not all of the study’s pre-specified primary outcomes have been reported; one or more primary outcomes is reported using measurements, analysis methods or subsets of the data (e.g. sub scales) that were not pre-specified.

	Unclear risk	One or more reported primary outcomes were not pre-specified (unless clear justification for their reporting is provided, such as an unexpected adverse effect); one or more outcomes of interest in the review are reported incompletely so that they cannot be entered in a meta-analysis; the study report fails to include results for a key outcome that would be expected to have been reported for such a study.
9. Other bias	Low risk	Evidence to suggest other problems identified with the study which might threaten the validity of the random allocation, attrition or data integrity and results of the trial.
	High risk	Evidence to suggest that the trial might be underpowered/problems with the random allocation process leading to potential self-selection bias/ issues of analysis not conducted using intent to treat analysis or evidence of missing data; concerns of attrition and measurement error including reliance on self-reported measures.
	Unclear risk	Insufficient information to permit judgement of low or high risk.

6. Risk of bias of RCTs: summary of the assessments

Risk of bias domain summaries

Random sequence	Although all the included studies were randomised trials, nearly 50% (10/22) provided an inadequate description and were rated as unclear by the reviewers (Brodie et al., 2009, Brown et al., 2013, Cornish et al., 1997, Coviello et al., 2010, Hanlon et al., 1975, Hanlon et al., 1977, Howells et al., 2002, Kinlock et al., 2005, Kurland et al., 1975, Parmar et al., 2017). Eleven studies were reported at low risk of bias (Bayanzadeh, 2004, Dolan et al., 2003, Dole et al., 1969, Kinlock et al., 2007, Konstenius et al., 2014, Lee et al., 2016, Lobmaier et al., 2010, Magura et al., 2009, McKenzie et al., 2012, Rich et al., 2015, Wright et al., 2011) and the remaining study was at high risk of bias (Cropsey et al., 2011).
Allocation concealment	Of the 22 included studies, five reported that the allocation process was concealed and were rated at low risk of bias (Dolan et al., 2003, Konstenius et al., 2014, Lee et al., 2016, Lobmaier et al., 2010, Wright et al., 2011). Five studies were rated at high risk of bias (Bayanzadeh, 2004, Cropsey et al., 2011, Magura et al., 2009, McKenzie et al., 2012, Rich et al., 2015). The remaining 12 studies were all rated as unclear (Brodie et al., 2009, Brown et al., 2013, Cornish et al., 1997, Dole et al., 1969, Hanlon et al., 1975, Hanlon et al., 1977, Howells et al., 2002, Kinlock et al., 2005, Kinlock et al., 2007, Konstenius et al., 2014, Kurland et al., 1975, Parmar et al., 2017) and the review authors were unable to decide whether allocation concealment had occurred within the studies.
Blinding	Blinding was assessed across four dimensions considering performance and detection bias across subjective and objective measures. Seven studies were rated as unclear risk of bias and provided no information on blinding across all four domains (Bayanzadeh, 2004, Brown et al., 2013, Cropsey et al., 2011, Dole et al., 1969,

	Kinlock et al., 2005, Kinlock et al., 2007, Magura et al., 2009). Eight studies were rated at high risk of bias for participant and personnel blinding (Cornish et al., 1997, Coviello et al., 2010, Dolan et al., 2003, Lee et al., 2016, Lobmaier et al., 2010, McKenzie et al., 2012, Rich et al., 2015, Wright et al., 2011). Seven studies reported use of a double-blind trial methodology and were rated low risk of bias (Brodie et al., 2009, Hanlon et al., 1975, Hanlon et al., 1977, Howells et al., 2002, Konstenius et al., 2014, Kurland et al., 1975, Parmar et al., 2017).
Incomplete outcome data	Three studies were noted at low risk of bias (Cornish et al., 1997, Dole et al., 1969, Kinlock et al., 2007) and 18 studies were noted to be at high risk of bias (Bayanzadeh, 2004, Brodie et al., 2009, Brown et al., 2013, Coviello et al., 2010, Cropsey et al., 2011, Dolan et al., 2003, Hanlon et al., 1975, Hanlon et al., 1977, Howells et al., 2002, Kinlock et al., 2005, Konstenius et al., 2014, Lee et al., 2016, Lobmaier et al., 2010, Magura et al., 2009, McKenzie et al., 2012, Parmar et al., 2017, Rich et al., 2015, Wright et al., 2011). One study was rated as unclear risk of bias (Kurland et al., 1975).
Selective reporting	Of the 20 studies, six studies were rated as unclear (Bayanzadeh, 2004, Cropsey et al., 2011, Dole et al., 1969, Hanlon et al., 1977, Kinlock et al., 2005, Kurland et al., 1975) and twelve studies were rated at low risk (Cornish et al., 1997, Coviello et al., 2010, Dolan et al., 2003, Howells et al., 2002, Kinlock et al., 2007, Konstenius et al., 2014, Lee et al., 2016, Lobmaier et al., 2010, Magura et al., 2009, McKenzie et al., 2012, Rich et al., 2015, Wright et al., 2011). Four studies were rated at high risk of bias (Brodie et al., 2009, Brown et al., 2013, Hanlon et al., 1975, Parmar et al., 2017).

7. Risk of bias of RCTs: detailed assessments

Bayanzadeh 2004

Bias	Review authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Participants were categorised into one of four lists based on their previous history of drug abuse. The random allocation was then chosen, using even and odd row numbers from each list
Allocation concealment (selection bias)	High risk	The lists generated with stratification were probably not concealed
Blinding of participants and personnel (performance bias) subjective outcomes	Unclear risk	No information reported
Blinding of participants and personnel (performance bias) objective outcomes	Unclear risk	No information on blinding reported
Blinding of outcome assessment (detection bias) subjective outcomes	Unclear risk	No information on blinding reported
Blinding of outcome assessment (detection bias) objective outcomes	Unclear risk	No information on blinding reported
	High risk	

Incomplete outcome data (attrition bias) all outcomes		After random allocation, 20 participants from the control group opted out of the research. At the end of the study attrition was high in both groups: for the intervention group $n = 38$ out of the original 60 allocated and for the control group $n = 31$ out of the original 60 allocated.
Selective reporting (reporting bias)	Unclear risk	Protocol for trial was not identified

Brodie 2009

Bias	Review authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Method for random sequence generation not reported
Allocation concealment (selection bias)	Unclear risk	Method for allocation of participants to treatment groups not reported
Blinding of participants and personnel (performance bias) subjective outcomes	Low risk	Staff, and personnel were both blind to treatment.
Blinding of participants and personnel (performance bias) objective outcomes	Low risk	Staff and personnel were both blind to treatment
Blinding of outcome assessment (detection bias) subjective outcomes	Unclear risk	Blinding of outcome assessors not reported
Blinding of outcome assessment (detection bias) objective outcomes	Unclear risk	Blinding of outcome assessors not reported
Incomplete outcome data (attrition bias) all outcomes	High risk	38% in the vigabatrin group and 58.5% in the placebo group were lost to follow-up. Outcomes reported for n randomised. Missing urine toxicology tests were considered positive.
Selective reporting (reporting bias)	High risk	Protocol identified for trial registration NCT00527683. Primary and secondary outcomes are clearly stated but some secondary mental health outcomes are not reported at follow-up.

Brown 2013

Bias	Review authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Random allocation noted no further information.
Allocation concealment (selection bias)	Unclear risk	No information provided
Blinding of participants and personnel (performance bias) subjective outcomes	Unclear risk	No information provided
Blinding of participants and personnel (performance bias) objective outcomes	Unclear risk	No information provided

Blinding of outcome assessment (detection bias) subjective outcomes	Unclear risk	No information provided
Blinding of outcome assessment (detection bias) objective outcomes	Unclear risk	No information provided
Incomplete outcome data (attrition bias) all outcomes	High risk	80% completing the 24-week assessment, 33% completing week 52 and 26% at follow-up.
Selective reporting (reporting bias)	High risk	Protocol reported as being available. However, on-going drug use (frequency and patterns of daily drug use), health services utilisation and urine tests are reported as being assessed, but no outcome data are reported.

Cornish 1997

Bias	Review authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Individuals were assigned at a ratio of 2:1 to naltrexone vs control
Allocation concealment (selection bias)	Unclear risk	Not reported
Blinding of participants and personnel (performance bias) subjective outcomes	High risk	Study description suggests that participants were not blind
Blinding of participants and personnel (performance bias) objective outcomes	High risk	Study description suggests that participants were not blind
Blinding of outcome assessment (detection bias) subjective outcomes	Unclear risk	No information was reported on whether the subjective measures were blinded
Blinding of outcome assessment (detection bias) objective outcomes	Low risk	Outcome assessors were blind
Incomplete outcome data (attrition bias) all outcomes	Low risk	ITT analyses completed.
Selective reporting (reporting bias)	Low risk	Study protocol referred to within the paper

Coviello 2010

Bias	Review authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Randomisation method unclear. Note that randomisation was balanced by using six variables
Allocation concealment (selection bias)	Unclear risk	No information provided
Blinding of participants and personnel (performance bias) subjective outcomes	High risk	The treatment as usual group were not blinded
Blinding of participants and personnel (performance bias) objective outcomes	High risk	The treatment as usual group were not blinded
Blinding of outcome assessment (detection bias) subjective outcomes	Unclear risk	No information was reported on whether the subjective measures were blinded

Blinding of outcome assessment (detection bias) objective outcomes	Unclear risk	No information was reported on whether the objective measures were blinded
Incomplete outcome data (attrition bias) all outcomes	High risk	A large amount of attrition was noted in the first week, and only one-third of participants remained at 6-month follow-up
Selective reporting (reporting bias)	Low risk	Study protocol referred to in the paper

Cropsey 2011

Bias	Review authors' judgement	Support for judgement
Random sequence generation (selection bias)	High risk	The first 9 participants deliberately allocated to intervention for practical reasons. Subsequently a random number table was used to allocate the remaining sample to the intervention or placebo.
Allocation concealment (selection bias)	High risk	First 9 participants deliberately allocated to intervention for practical reasons. Use of sealed envelopes for the remaining sample
Blinding of participants and personnel (performance bias) subjective outcomes	Unclear risk	This trial began as an open label trial then became a double-blind trial of participants and providers on all outcomes. Some concerns about contamination issues with the placebo group but difficult to assess to what extent the blinding might have been affected.
Blinding of participants and personnel (performance bias) objective outcomes	Unclear risk	This trial began as an open label trial then became a double-blind trial of participants and providers on all outcomes. Some concerns about contamination issues with the placebo group but difficult to assess to what extent the blinding might have been affected.
Blinding of outcome assessment (detection bias) subjective outcomes	Unclear risk	No evidence to provide information about whether the assessors who conducted the outcome assessments were blind
Blinding of outcome assessment (detection bias) objective outcomes	Unclear risk	No evidence to provide information about whether the assessors who conducted the outcome assessments were blind
Incomplete outcome data (attrition bias) all outcomes	Unclear risk	A total of 8 individuals (22%) were not included in the final analysis after randomisation. It is unclear whether an ITT analyses was conducted.
Selective reporting (reporting bias)	High risk	No protocol identified.

Dolan 2003

Bias	Review authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Group allocation was based on block randomisation. A sequential list of case numbers was matched to group allocations in blocks of ten by randomly drawing five cards labelled "control" and five cards labelled "treatment" from an envelope. This procedure was repeated for each block of ten

		sequential case numbers. The list of case numbers and group allocation was held by a researcher not involved in recruiting or interviewing inmates. The trial nurses responsible for assessing, recruiting and interviewing inmates had no access to these lists.
Allocation concealment (selection bias)	Low risk	Allocation held by researcher not involved in recruiting or interviewing participants. Trial nurses had no access to lists
Blinding of participants and personnel (performance bias) subjective outcomes	High risk	Treatment and comparator (methadone or wait list) would not permit blinding
Blinding of participants and personnel (performance bias) objective outcomes	High risk	Treatment and comparator (methadone or wait list) would not permit blinding
Blinding of outcome assessment (detection bias) subjective outcomes	Unclear risk	No information was provided
Blinding of outcome assessment (detection bias) objective outcomes	Unclear risk	No information was provided
Incomplete outcome data (attrition bias) all outcomes	High risk	Attrition > 30% in both groups and ITT not undertaken. At follow-up, 129 (68%) treated and 124 (65%) control subjects who had been in continuous custody were re-interviewed. 29 treated and 33 control subjects had been released from prison and were excluded. No data on other participants not accounted for at follow-up
Selective reporting (reporting bias)	Low risk	Protocol information matched all outcome measures

Dole 1969

Bias	Review authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Allocation by lottery, no further details of the study method provided
Allocation concealment (selection bias)	Unclear risk	Not reported
Blinding of participants and personnel (performance bias) subjective outcomes	Unclear risk	No information provided
Blinding of participants and personnel (performance bias) objective outcomes	Unclear risk	No information provided
Blinding of outcome assessment (detection bias) subjective outcomes	Unclear risk	No information provided
Blinding of outcome assessment (detection bias) objective outcomes	Unclear risk	No information provided
Incomplete outcome data (attrition bias) all outcomes	Low risk	No attrition reported on any of the key outcome measures
Selective reporting (reporting bias)	Unclear risk	Protocol for the trial not identified.

Hanlon 1975

Bias	Support for judgement
------	-----------------------

	Review authors' judgement	
Random sequence generation (selection bias)	Unclear risk	Reported as randomly assigned no details provided
Allocation concealment (selection bias)	Unclear risk	Not reported
Blinding of participants and personnel (performance bias) subjective outcomes	Low risk	Reported as double-blind study
Blinding of participants and personnel (performance bias) objective outcomes	Low risk	Reported as double-blind study
Blinding of outcome assessment (detection bias) subjective outcomes	Unclear risk	Not reported in the study
Blinding of outcome assessment (detection bias) objective outcomes	Unclear risk	Not reported in the study
Incomplete outcome data (attrition bias) all outcomes	High risk	Attrition across the two groups was high. In the intervention group 21 (60%) people did not complete the intervention and in the comparison intervention 17(48.6%) did not complete the intervention. No intent to treat analysis is provided.
Selective reporting (reporting bias)	High risk	Primary and secondary outcomes are not reported separately. No trial protocol is reported. The results were divided into those who completed and those who did not complete the intervention.

Hanlon 1977

Bias	Review authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Not reported
Allocation concealment (selection bias)	Unclear risk	Not reported
Blinding of participants and personnel (performance bias) subjective outcomes	Low risk	Reported as a double-blind trial
Blinding of participants and personnel (performance bias) objective outcomes	Low risk	Reported as a double-blind trial
Blinding of outcome assessment (detection bias) subjective outcomes	Unclear risk	Not reported
Blinding of outcome assessment (detection bias) objective outcomes	Unclear risk	Not reported
Incomplete outcome data (attrition bias) all outcomes	High risk	Of the original 154 parolees referred and assigned to one of the two treatment arms—57 did not receive study medication and were excluded. This reduced the resulting sample size on which the

		analyses were performed to 55 in the intervention group and 42 in the placebo group.
Selective reporting (reporting bias)	Unclear risk	Not reported—no evidence of a trial protocol

Howells 2002

Bias	Review authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	The authors report "The pharmacist who made up the medication used a simple randomisation procedure to allocate each participant to one arm of the trial" but no further description is reported.
Allocation concealment (selection bias)	Unclear risk	The authors report "The independent pharmacy team at the prison oversaw the randomisation and blinding procedure...", but no statement that allocation was concealed
Blinding of participants and personnel (performance bias) subjective outcomes	Low risk	"...both the patient and health centre clinicians were blind to the assigned treatment group"
Blinding of participants and personnel (performance bias) objective outcomes	Low risk	"...both the patient and health centre clinicians were blind to the assigned treatment group"
Blinding of outcome assessment (detection bias) subjective outcomes	Low risk	"...blinding was maintained during treatment of the patients and during data entry and analysis"
Blinding of outcome assessment (detection bias) objective outcomes	Low risk	"...blinding was maintained during treatment of the patients and during data entry and analysis"
Incomplete outcome data (attrition bias) all outcomes	High risk	Twenty-one participants (27.63%) (13/32 lofexidine, 8/36 methadone) were withdrawn from the trial prematurely. ITT not used, data analysed per-protocol
Selective reporting (reporting bias)	Low risk	The authors indicate that there was a protocol for the study ("Patient safety elements in the protocol were as follows:") and primary and secondary outcomes are clearly defined. Outcome data for the primary and secondary outcomes are reported

Kinlock 2005

Bias	Review authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	No information reported other than stated 'random'
Allocation concealment (selection bias)	Unclear risk	No information reported
Blinding of participants and personnel (performance bias) subjective outcomes	Unclear risk	No information reported
Blinding of participants and personnel (performance bias) objective outcomes	Unclear risk	No information reported

Blinding of outcome assessment (detection bias) subjective outcomes	Unclear risk	No information reported
Blinding of outcome assessment (detection bias) objective outcomes	Unclear risk	No information reported
Incomplete outcome data (attrition bias) all outcomes	High risk	Follow-up interviews were conducted on 66, or 80% of the 83 participants who were eligible; 22 of 26 experimental participants (85%), 31 of 38 control participants (82%), and 13 of 19 who declined participation in the experimental condition (68%).
Selective reporting (reporting bias)	Unclear risk	No protocol recorded.

Kinlock 2007

Bias	Review authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Block randomisation
Allocation concealment (selection bias)	Unclear risk	No information reported
Blinding of participants and personnel (performance bias) subjective outcomes	Unclear risk	No information reported
Blinding of participants and personnel (performance bias) objective outcomes	Unclear risk	No information reported
Blinding of outcome assessment (detection bias) subjective outcomes	Unclear risk	No information reported
Blinding of outcome assessment (detection bias) objective outcomes	Unclear risk	No information reported
Incomplete outcome data (attrition bias) all outcomes	Low risk	One month post-release follow-up assessments were conducted on 200, or 96.2% of the 208 participants due for this assessment; 64 of 70 (91.4%) in the counselling only condition, 66 of 68 (97.1%) in the counselling + transfer condition, and 70 of 70 (100.0%) in the counselling + methadone condition
Selective reporting (reporting bias)	Low risk	Study protocol referenced and supported outcome measures.

Konstenius 2014

Bias	Review authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	The randomisation list was generated by an independent pharmacist using the computer-based programme design by Trombult Programming between March 2007 and February 2011.
Allocation concealment (selection bias)	Low risk	

		The randomisation code was retained by the Karolinska Pharmacy and disclosed after the end of the trial. No interim analysis was performed.
Blinding of participants and personnel (performance bias) subjective outcomes	Low risk	Although efforts were made to maintain blinding, 48% of the participants receiving MPH and 48% of the placebo group identified their medication correctly during the titration phase or after reaching the maximum dose.
Blinding of participants and personnel (performance bias) objective outcomes	Low risk	Although efforts were made to maintain blinding, 48% of the participants receiving MPH and 48% of the placebo group identified their medication correctly during the titration phase or after reaching the maximum dose.
Blinding of outcome assessment (detection bias) subjective outcomes	Unclear risk	Not reported if assessor was blind
Blinding of outcome assessment (detection bias) objective outcomes	Unclear risk	Not reported if assessor was blind
Incomplete outcome data (attrition bias) all outcomes	High risk	> 10% in both groups did not complete the trial, more in the placebo group than the intervention group.
Selective reporting (reporting bias)	Low risk	The trial was registered in the International Standard Randomised Controlled Trial Number Register (ISRCTN) at http:// www.controlled-trials.com/ISRCTN77940178 .

Kurland 1975

Bias	Review authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Not reported
Allocation concealment (selection bias)	Unclear risk	Not reported
Blinding of participants and personnel (performance bias) subjective outcomes	Low risk	Reported as double-blind trial
Blinding of participants and personnel (performance bias) objective outcomes	Low risk	Reported as double-blind trial
Blinding of outcome assessment (detection bias) subjective outcomes	Unclear risk	Not reported
Blinding of outcome assessment (detection bias) objective outcomes	Unclear risk	Not reported
Incomplete outcome data (attrition bias) all outcomes	Unclear risk	Reporting is given by group but no reasons for withdrawal are provided
Selective reporting (reporting bias)	Unclear risk	No evidence of a protocol provided

Lee 2016

Bias	Review authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	

Allocation concealment (selection bias)	Low risk	An independent, centralised, automated telephone system made the treatment assignments after eligibility of the participants was confirmed Sealed envelopes were sequenced and shuffled. Participants and researchers could not foresee assignment.
Blinding of participants and personnel (performance bias) subjective outcomes	High risk	This is an open trial no blinding was conducted
Blinding of participants and personnel (performance bias) objective outcomes	High risk	This is an open trial no blinding was conducted
Blinding of outcome assessment (detection bias) subjective outcomes	High risk	This is an open trial no blinding was conducted
Blinding of outcome assessment (detection bias) objective outcomes	High risk	This is an open trial no blinding was conducted
Incomplete outcome data (attrition bias) all outcomes	High risk	13% were lost to follow-up in the naltrexone group and 8% in usual care, and some outcomes were only available for completers.
Selective reporting (reporting bias)	Low risk	Trial protocol NCT 00781898 is registered and outcomes are divided clearly into primary and secondary outcomes

Lobmaier 2010

Bias	Review authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Treatment allocation sequence performed at an independent centre using a permuted block protocol
Allocation concealment (selection bias)	Low risk	Sequentially numbered, sealed, opaque envelopes
Blinding of participants and personnel (performance bias) subjective outcomes	High risk	“the treatment conditions were not blind and may have increased risk of performance bias”
Blinding of participants and personnel (performance bias) objective outcomes	High risk	“the treatment conditions were not blind and may have increased risk of performance bias”
Blinding of outcome assessment (detection bias) subjective outcomes	Unclear risk	No information provided
Blinding of outcome assessment (detection bias) objective outcomes	Unclear risk	No information provided
Incomplete outcome data (attrition bias) all outcomes	High risk	In the naltrexone implant arm of the trial, 7 of 23 inmates did not initiate treatment: all 7 reported a preference for methadone or a non-study treatment. In the methadone treatment arm, 10 of 21 inmates did not initiate treatment and dropped out before release: 60% of the methadone group drop-outs reported that they intended to start, but were not granted the possibility to continue with

		methadone maintenance upon release by community treatment providers.
Selective reporting (reporting bias)	Low risk	The study was funded by the Research Council of Norway and registered publicly at http://clinicaltrials.gov , identifier NCT00204243. All primary and secondary outcomes reported

Magura 2009

Bias	Review authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Random number generator used. Allocation was originally 1:1, but loss in one group meant that treatment-adaptive randomisation was used at a ratio of 7:3
Allocation concealment (selection bias)	High risk	Project director was naive to allocation, but research assistant was not
Blinding of participants and personnel (performance bias) subjective outcomes	Unclear risk	No information provided
Blinding of participants and personnel (performance bias) objective outcomes	Unclear risk	No information provided
Blinding of outcome assessment (detection bias) subjective outcomes	Unclear risk	No information provided
Blinding of outcome assessment (detection bias) objective outcomes	Unclear risk	No information provided
Incomplete outcome data (attrition bias) all outcomes	High risk	Some attrition occurred before medication was received by buprenorphine-assigned participants. Interview follow-ups were attempted for 60 buprenorphine subjects, of whom 43 (72%) were interviewed at follow-up, and for 56 methadone subjects, of whom 38 (68%) were interviewed.
Selective reporting (reporting bias)	Low risk	The study was approved by the Institutional Review Boards of National Development and Research Institutes (NDRI) and DOHMH. The ClinicalTrials.gov identifier is NCT00367302. Protocol listed all primary and secondary outcomes

McKenzie 2012

Bias	Review authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer-generated random permutation. Urn randomisation to stratify on the basis of sex and race.
Allocation concealment (selection bias)	High risk	Open-label trial no mention of blinding
	High risk	Open-label trial no mention of blinding

Blinding of participants and personnel (performance bias) subjective outcomes		
Blinding of participants and personnel (performance bias) objective outcomes	High risk	Open-label trial no mention of blinding
Blinding of outcome assessment (detection bias) subjective outcomes	Unclear risk	The assessment of outcomes was not described
Blinding of outcome assessment (detection bias) objective outcomes	Unclear risk	The assessment of outcomes was not described
Incomplete outcome data (attrition bias) all outcomes	High risk	There was substantial cross over from arms 1 and 3 to 2. The authors suggested that the treatment completer analysis is more reliable than the ITT analysis. Data for the completers only are presented.
Selective reporting (reporting bias)	Low risk	Protocol and trial is registered see NCT00142935. All outcomes are reported as expected.

Parmar 2016

Bias	Review authors' judgement	Support for judgement
Random sequence generation (selection bias)	Unclear risk	Randomisation by MRC trials unit. No further information provided
Allocation concealment (selection bias)	Unclear risk	Allocation concealment not reported
Blinding of participants and personnel (performance bias) subjective outcomes	Low risk	The trial was double-blind prior to release so that, whilst the participant was still in custody and pre-release, neither the participant, prison-based N-ALIVE staff nor prison staff knew the allocation. Participants learned their allocation when they opened the pack at the time of their release.
Blinding of participants and personnel (performance bias) objective outcomes	Low risk	The trial was double-blind prior to release so that, whilst the participant was still in custody and pre-release, neither the participant, prison-based N-ALIVE staff nor prison staff knew the allocation. Participants learned their allocation when they opened the pack at the time of their release.
Blinding of outcome assessment (detection bias) subjective outcomes	High risk	The self-reported questionnaire identified the participant's randomised assignment and the time interval between the preceding N-ALIVE release date and completion date.
Blinding of outcome assessment (detection bias) objective outcomes	Unclear risk	Not applicable—no objective measures reported in the trial.
Incomplete outcome data (attrition bias) all outcomes	High risk	Approximately 20% attrition in each group—due to those allocated did not get their allocation as intended.
Selective reporting (reporting bias)	High risk	Study protocol is reported but not all of the study's pre-specified primary outcomes have been reported due to the trial stopping early. Protocol (ISRCTN34044390)

Rich 2015

Bias	Review authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Computer generated random permutation. Urn randomisation to stratify on the basis of sex and race. Independent of enrolment and consent process. Random assignment was obtained from a staff member who had no direct contact with participants
Allocation concealment (selection bias)	High risk	No blinding conducted using an open-label trial design
Blinding of participants and personnel (performance bias) subjective outcomes	High risk	No blinding conducted using an open-label trial design
Blinding of participants and personnel (performance bias) objective outcomes	High risk	No blinding conducted using an open-label trial design
Blinding of outcome assessment (detection bias) subjective outcomes	Unclear risk	Blinding of outcome measures not clearly reported
Blinding of outcome assessment (detection bias) objective outcomes	Unclear risk	Blinding of outcome measures not clearly reported
Incomplete outcome data (attrition bias) all outcomes	High risk	In the methadone continuation group data were available for 114/142 (80%). In the tapered withdrawal group data were available for 109/141 (77%). There is some attrition.
Selective reporting (reporting bias)	High risk	Study protocol is reported and all of specified outcomes are measured Protocol (NCT01874964)

Wright 2011

Bias	Review authors' judgement	Support for judgement
Random sequence generation (selection bias)	Low risk	Randomisation sequence (with random block size) was generated using Microsoft Excel RAND function
Allocation concealment (selection bias)	Low risk	Sealed, opaque, consecutively numbered envelopes concealing the name of the allocated intervention were prepared by a researcher who had no contact with participants.
Blinding of participants and personnel (performance bias) subjective outcomes	High risk	Open label "The prescribing doctor randomised by opening the next envelope and prescribing the intervention named inside. Both prisoner and doctor were blind to the intervention until this point".
Blinding of participants and personnel (performance bias) objective outcomes	High risk	Open label "The prescribing doctor randomised by opening the next envelope and prescribing the intervention named inside. Both prisoner and doctor were blind to the intervention until this point".

Blinding of outcome assessment (detection bias) subjective outcomes	Unclear risk	No statement regarding blinding of individual who undertook the biochemical urine tests.
Blinding of outcome assessment (detection bias) objective outcomes	Unclear risk	No statement regarding blinding of individual who recorded self-reported or clinical notes.
Incomplete outcome data (attrition bias) all outcomes	High risk	High levels of attrition. 50% buprenorphine and 45% methadone did not provide urine sample at day 8. 65% and 62% at 1 month, 80% and 85% at 3 months and 86% and 91% at 6 months.
Selective reporting (reporting bias)	Low risk	Published study protocol identified. All primary and secondary outcomes reported.
