## Abstract

### Introduction

In India, the retail prices of bidis and cigarettes varied between the two Global Adult Tobacco Surveys (GATS) conducted in 2009/10 and 2016/17. The relationship between the retail price of smoked tobacco products and their use is unclear for India. Our study thus aimed to use available datasets to investigate the association between the retail price and current smoking status of bidis and cigarettes in India.

### Methods

Current smoking status data for bidis and cigarettes were obtained from the two GATS rounds. The average state-level retail prices of bidis and cigarettes were obtained from India's Consumer Price Index- Industrial Workers database. Descriptive statistics were used to describe current smoking status patterns. Generalized Linear Mixed Models (GLMM) were used to investigate the association between the retail prices and current smoking status of bidis and cigarettes.

### Results

For cigarettes, an increase in the average retail price by one Indian Rupee was associated with a reduction in the odds of being a current smoker of 7% (OR 0.925 [95% CI = 0.918 – 0.932],  $p < 0.001$ ). For bidis, the association between the retail price and current smoking status was not statistically significant (OR 1.01 [95% CI = 1.00 - 1.02],  $p = 0.082$ ).

### Conclusions

Current increases in the retail prices of tobacco products in India seem to have an impact on the use of cigarettes but not bidis. This highlights the need for tobacco product tax increases that result in sufficient retail prices increases to make all tobacco products less affordable and reduce their use.

## Explanation letter

Thank you for the valuable comments from reviewers on our manuscript and for opportunity to improve the same.

All the authors have reviewed the manuscript and tried our best to clarify the queries. We are now submitting our revised manuscript with highlights along with explanation to reviewers' comments. If

any further modifications are required, we are glad to address them.

Kindly consider our revised manuscript in your esteemed journal.

Looking forward for positive response.

With best regards,

The association between the retail price of manufactured cigarettes and bidis on current smoking status in India

## ABSTRACT

### Introduction:

In India, the retail prices of bidis and cigarettes varied between the two Global Adult Tobacco Surveys (GATS) conducted in 2009/10 and 2016/17. The relationship between the retail price of smoked tobacco products and their use is unclear for India. Our study thus aimed to use available datasets to investigate the association between the retail price and current smoking status of bidis and cigarettes in India.

### Methods:

Current smoking status data for bidis and cigarettes were obtained from the two GATS rounds. The average state-level retail prices of bidis and cigarettes were obtained from India's Consumer Price Index- Industrial Workers database. Descriptive statistics were used to describe current smoking status patterns. Generalized Linear Mixed Models (GLMM) were used to investigate the association between the retail prices and current smoking status of bidis and cigarettes.

### Results:

For cigarettes, an increase in the average retail price by one Indian Rupee was associated with a reduction in the odds of being a current smoker of 7% (OR 0.925 [95% CI = 0.918 – 0.932],  $p < 0.001$ ). For bidis, the association between the retail price and current smoking status was not statistically significant (OR 1.01 [95% CI = 1.00 - 1.02],  $p = 0.082$ ).

### Conclusions:

Current increases in the retail prices of tobacco products in India seem to have an impact on the use of cigarettes but not bidis. This highlights the need for tobacco product tax increases that result in sufficient retail prices increases to make all tobacco products less affordable and reduce their use.

**Keywords:** Tobacco Use, GATS, Price, Current smoking.

## Introduction

Tobacco use is one of the leading causes of death globally.<sup>1</sup> Eighty percent of mortality due to tobacco use is in low- and middle-income countries (LMICs).<sup>2</sup> Tobacco smoking can result in serious health consequences such as tuberculosis, respiratory diseases, cardiovascular diseases and neoplasm.<sup>3</sup> Globally, India occupies second position in both consumption and production of tobacco.<sup>3,4</sup> Bidis (tobacco hand-rolled, inexpensive, small and wrapped in dried tendu leaves) and cigarettes are two common tobacco smoking forms in India.<sup>5</sup> Compared to cigarettes, bidis are commonly used by low socio-economic status people due to easy availability and lower cost.<sup>6</sup> Unfortunately, bidi smoking has been reported to be a stronger risk factor for cancer of the hypopharynx and supraglottis as it appears to deliver some toxic components of tobacco smoke in greater amounts than conventional cigarettes.<sup>7</sup> The life expectancy of cigarette and bidi smokers is on an average 6-10 years less than that of non-smokers.<sup>9</sup> According to India's Global Adult Tobacco Surveys (GATS), the prevalence of tobacco use among adults in India has decreased from 34.6% to 28.6% between 2009/10 and 2016/17, with 42.4% of men and 14.2% of women currently using tobacco.<sup>10</sup> Similarly, there has been a decline in the prevalence of current bidi smoking from 9.2% to 7.7% and of current cigarette smokers from 5.7% to 4.0% in the inter-survey period.<sup>10</sup> The consumption pattern of bidis and cigarettes varies in the 29 states and seven union territories in India due to diversity in culture, habits and economic status.<sup>3,5,11,12,13</sup> For instance current prevalence of smoked forms of tobacco use in southern state of Karnataka was 11.9% in 2009/10 and 8.8% in 2016/17, whereas in the northern territory of Delhi this was 17.4% and 11.3% respectively.<sup>14,15</sup>

Tobacco product price is an important economic determinant of tobacco consumption.<sup>16</sup> Policies that increase the real consumer price (i.e., inflation adjusted) of tobacco products have been shown to reduce tobacco use, particularly if they reduce affordability of the products (i.e., the percentage of income required to buy specific units of a tobacco product).<sup>17,18</sup> Taxation of tobacco products for example represents one of the most effective means of tobacco control: a 10% increase in tax could reduce cigarette smoking by 2%.<sup>19,20</sup> Tobacco taxes in India are complex in structure. During the study period, both central and state governments levied taxes on tobacco products. For example, for bidis and cigarettes, the central government imposed tax on product characteristics such as stick length, presence of filter, machine or hand made and quantity. The state governments on the other hand had the authority to impose Value-added Tax (VAT) on tobacco products in the GATS period,

resulting in varying tobacco product taxes and prices across states.<sup>21</sup> This has been cited as one of the reasons for the observed variations in tobacco use prevalence and consumption patterns across states.<sup>3,22,23</sup>

Tobacco companies work to limit the impact of taxes on tobacco product prices through market segmentation and setting lower prices for those consumers who are most price-sensitive, e.g., those of lower socio-economic status. They achieve this for example through having different price tiers or point-of-sale price discounts offers. In order to offset these tobacco company strategies, there is an increased interest in non-tax policy approaches to raising tobacco product prices, for example minimum price laws that set a single floor price below which cigarettes cannot be sold.<sup>24,25,26</sup> Such strategies have been shown, through sales modelling studies, to potentially reduce smoking prevalence, with suggestions that the effects may be greater than achieved through taxation alone.<sup>24,25,27</sup> They also seem to have a greater relative impact on smokers in lower socio-economic groups as tobacco product prices generally tend to be lower more income-deprived neighbourhoods, hence could help reduce health inequalities.<sup>25,27, 28</sup> Studies have demonstrated that higher cigarette prices have a negative effect on cigarette consumption.<sup>29,25</sup> A recent study concluded that higher bidi and cigarette prices can lower the probability of bidi or cigarette smoking onset in India.<sup>6</sup> However, the relationship between the retail prices of tobacco products and the prevalence of their use in India is unclear. In our study, we thus investigated the association between the retail prices and current smoking of cigarettes and bidis, adjusting for various socio-demographic factors and accounting for state-level variations.

## Methods

The study was conducted after obtaining ethics committee approval from the University of York, UK (HSRGC/2019/346/E) and Manipal Academy of Higher Education, India (MAHE EC/002/2021)

### Data sources

Our analysis was based on data from the GATS in India and the Consumer Price Index for Industrial Workers (CPI-IW) database managed by the Labour Bureau Government of India (<http://labourbureaucpi.gov.in/webform6.aspx>).<sup>30</sup>

India's Ministry of Health & Family Welfare conducted two rounds of the GATS, one in 2009/10 (GATS-1), and the other in 2016/17 (GATS-2).<sup>14,15</sup> The GATS targets all Indian residents, aged 15 and above, and living in their primary residence prior to the survey date. The GATS collects information on respondent's demographic and socio-economic characteristics, tobacco use (smoking and smokeless) and cessation, second-hand smoke exposure, tobacco related expenditures, media exposure to anti-tobacco information and tobacco advertisement, knowledge attitudes and perceptions towards tobacco use. There were 69,296 and 74,037 individual observations in GATS-1 and GATS-2, respectively. Data from these two GATS were combined for the analysis.

The CPI-IW database publishes state-level average monthly retail prices of tobacco products computed using data from selected industrially important centres based on brand name, filter/nonfilter (for cigarettes), and number of sticks or units. The database contains information on a large number of local or subnational bidi brands, with one popular brand (Ganesh bidi) being identifiable as a common brand with national reach. The information of cigarette brands on database were recorded with length shorter than 69 mm category of local or subnational brands. The database covers data starting from January 2006 to present. We assumed that any impact of change in retail price on individual-level smoking status would take at least a year to manifest,<sup>31</sup> hence we retrieved 2008 and 2015 retail prices which are one year prior to GATS-1 and GATS-2 respectively.

### **Dependent variables:**

For the two dependent variables, current bidi smoking status and current cigarette smoking status, we used responses to the following GATS question to categorise respondents as current bidi smoker/non-smoker and current cigarette smoker/non-smoker: "On average, how many of the following products do you currently smoke each day? Also, let me know if you smoke the product, but not every day". Those who reported smoking one or more bidi each day, or smoking bidi but not every day were considered as current bidi smokers; whilst those who indicated they did not smoke any bidi were current non-smokers (bidi). Similarly, those who reported smoking one or more manufactured cigarettes each day, or smoking manufactured cigarettes but not every day were considered as current cigarette smokers; whilst those who indicated they did not smoke any manufactured cigarettes were current non-smokers (cigarette). The two variables were categorised independent of each other and did

not consider dual users, i.e., smoking bidi and cigarette at the same time, which constituted approximately 1.4% of our dataset.

### Independent variables:

The average monthly retail prices, in Indian Rupees (Rs), for bidi and manufactured cigarettes were obtained from the CPI-IW database. As the pack sizes varied across products and states, the recorded retail prices were converted into prices of standard pack sizes in the Indian market: 25 sticks of bidis and 10 sticks of cigarettes. For each of the products, i.e., bidis and cigarettes, the retail price per standard pack for a state was estimated with a two-step average method: first calculate the mean price of all products over the entire year for each centre, then calculate the average of the mean prices of all centres in a state as the retail price of a product for that state.

The following GATS socio-demographic variables were considered for the analysis based on empirical or theoretical literature reporting their association with current smoking status: age (as a continuous variable), residence (rural or urban), gender (female or male), level of education (No formal schooling, Primary school completed, secondary school completed, higher secondary school completed or college and above completed), work status (Government employee, non-government employee, self-employed, student, homemaker, retired or unemployed), smoking allowed in every room of house (yes or no), and wealth quintile (1=Lower, 2=Lower-middle, 3=Middle, 4=Middle-upper or 5=Upper) based on modified Kuppaswamy socioeconomic scale 2020.<sup>32</sup> For our analysis, a few variables were recategorised from their original categories in GATS due to very few observations within each state. Specifically, for level of education, “Less than primary school completed” and “primary school completed” were recategorised as “primary school completed”, “less than secondary school completed” and “secondary school completed” were recategorised as “secondary school completed”, “college / university completed” and “post graduate degree completed” were recategorised as “College and above Completed”; while “higher secondary school completed” and “No formal schooling” remained unchanged for the analysis. For work status, the GATS categories ‘daily wage/casual labourer’ and ‘self-employed’ were recategorised as ‘self-employed’; whilst categories ‘unemployed able to work’, and ‘unemployed unable to work’ were recategorised as ‘unemployed’; and categories ‘government employee’, ‘non-government employee’, ‘student’, ‘homemaker’ and ‘retired’

remained unchanged for the analysis. Values were considered missing where responses were blank, or the respondent refused to answer. Observations with missing values for any of the included variables were excluded from the analysis.

## Data analysis

The analysis was carried out using RStudio software version 3.6.1 (<https://www.rstudio.com/>). We conducted descriptive analysis, summarising the average age of current smokers at the time of the survey, and the proportion of current smokers by the GATS derived socio-demographic variables, separately for bidi and manufactured cigarettes. To take into account the variation between states and GATS waves and predictors on both state-level and individual-level, we used Generalized Linear Mixed Models (GLMM) to analyse the association between retail price and current smoking status across the two GATS survey time points for bidi and cigarette separately, controlling for socio-demographic variables, with states and GATS waves as random effect to account for clustering effect on state level and survey level.<sup>33</sup>

First, multilevel mixed-effects univariate logistic regression analyses were conducted to assess the empirical relationship between each independent variable and each dependent variable. The univariate analyses were used to select factors with  $p < 0.2$  for inclusion in the multivariate analyses.<sup>34,35</sup> For both current bidi smoking status and current cigarette smoking status, all independent variables had a  $p$  value  $< 0.2$  in the univariate analyses, and were therefore included in multivariate analyses. For the multivariate analysis, odds ratios (ORs) and their 95% confidence intervals were used as the measures of association, using a significance level of 0.05.

Hosmer-lemeshow test (HL test) and Akaike Information Criterion (AIC) were used to assess the model goodness of fit. Intra-class correlation coefficients (ICCs) was reported to attribute the variance accounted for by the states and the GATS survey period.

## Results

For bidi, average retail price data was available for 23 out of the 24 states included in the CPI-IW database. For these 23 states, we retrieved 82.3% observations from GATS-1 (57,012 individual observations out of 69,296) and 81.0% observations from GATS-2 (59,985 individual observations out of 74,037), constituting a total of 116,997 observations after

excluding observations with data missing on covariates. For cigarette smoking, average retail price data was available for all 24 states in the CPI-IW database. For these 24 states we retrieved 84.8% and 84.4% observations respectively from GATS-1 (58,735 individual observations out of 69,296) and from GATS-2 (62,476 individual observations out of 74,037), with a total of 121,211 after excluding observations with data missing on covariates.

In GATS-1, the prevalence of bidi smoking and cigarette smoking in the analysis samples were 8.9% (5,085/57,012) and 6.1% (3,603/58,735) respectively; and in GATS-2 these were 7.8% (4,695/59,985) and 3.3% (2,055/62,476) respectively. The results of descriptive analysis are presented in Table 1. Table 2 shows the results of univariate analyses: all considered factors had a p value <0.2 for both bidis and cigarettes and were included in the multivariate analysis.

In the multivariate analysis, the average retail price of cigarette was statistically significantly associated with current smoking status for cigarettes. When the average retail price increases by one Indian Rupee, the odds of being a current smoker are reduced by 7% (OR 0.925 [95% CI = 0.918 – 0.932], p <0.001) (Table 3). An ICC of 23% and 11% was obtained, implying 23% of variation in current cigarette smoking status is attributed to GATS survey periods and 11% attributed to state variation. For bidis, the association between the retail price and current smoking status was not statistically significant (OR 1.01 [95% CI = 1.00 - 1.02], p = 0.082). An ICC of 1% and 11% , indicated that only 1% of the variation in current smoking status is attributed to GATS survey period and 11% attributed to state variation.

Older individuals were more likely to be bidi smoker, while the difference in age for cigarette smoking were not statistically significant. Those who are male, were more likely to be current smokers for both bidis and cigarettes compared to females. In addition, those living in a household where smoking is allowed in every room were more likely to be current cigarette and bidi smokers than those living in a household where smoking is not allowed in every room. Whilst those living in urban areas were less likely to be current bidi smokers than those living in the rural areas (OR 0.83 [95% CI=0.78,0.88], p<0.001), they were more likely to be current cigarette smokers than those living in the rural areas. Comparing to those completed college or above education, people with lower education levels (Primary, secondary and higher secondary schooling) were more likely to be smoking bidi. For cigarette, while those in the middle levels of education were more likely to be smoking than those with college and above education, no difference was found between the lowest level of education category (no formal schooling) and

the highest (college and above). Student, Home maker, unemployed and retired were less likely to be current bidi and cigarette smokers as compared to government employee. Self-employed people were less likely than government employees to be smoking cigarettes but did not differ in likelihood of smoking bidi. Those in the lower, lower-middle, middle and middle-upper wealth quintile were more likely to be current bidi smokers, while those in the upper wealth quintile were more likely to be cigarette smokers.

## Discussion

In our study, an increase in the average retail price per standard pack of commonly sold brands of manufactured cigarettes by one Indian Rupee was accompanied by a reduction in the odds of being a current smoker of 7%, taking clustering effect of states, GATS survey periods and other socio-demographic factors into consideration. For bidis, the association between the retail price and current smoking status was not statistically significant.

In India, tax levels for bidis are significantly lower than those for cigarettes and smokeless tobacco products.<sup>36</sup> In addition, the bidi industry has many small producers who take advantage of the tax concession that are available for small producers.<sup>36,37</sup> Bidis are therefore cheaper, and tend to be more affordable at lower increments in tax/price when compared to cigarettes.<sup>36,38</sup> For example, in their projection of the affordability of cigarettes and bidis from 2017 to 2025, Rana and colleagues found that whilst the affordability for cigarettes decreased to -9.9% after a 100% increase in tax, that of bidi decreased to -8.61% only after a 200% increase in tax by the end of 2025.<sup>39</sup>

Because they are cheaper, bidis are usually smoked by the people of lower socioeconomic status, whilst cigarettes tend to be smoked by those of higher socioeconomic status.<sup>40</sup> This is consistent with our findings where those in the upper wealth quantile were less likely to be bidi smokers but more likely to be cigarette smokers when compared to those in the lower to middle-upper wealth quantiles. However in the present study we could not capture the scenario of switching to cheaper products since we could not follow individual decisions with the secondary database. With regards to residence, those in urban areas were more likely to be current smokers of manufactured cigarettes, and less likely to be current smokers of bidis than those in the rural areas in our study. Our observations with respect to education status revealed a notable reduction in the likelihood of cigarette smoking with increasing levels of education. In contrast, the education effect on bidi smoking, although existed, was not as prominent. However, the reduction in users of cigarettes was higher in each education

category than the bidis between the two GATS surveys. Although consumers in India perceive bidis to be an inferior product relative to cigarettes, there is still a possibility that cigarette smokers switch to bidi smoking when they cannot afford to buy cigarettes because of its high price.<sup>41,39</sup> Thus, the fact that current increases in the price of bidis do not seem to reduce the likelihood of bidis use by individuals has a potential to result in widening of health inequalities between the rich and the poor, the educated and uneducated, and rural versus urban populations. In addition, if cigarette smokers shift to bidi use as the cigarettes become more expensive, the change in smoking prevalence in the country will be negligible.<sup>39</sup>

In India, retail prices of tobacco products vary widely between states due to a number of reasons. For example, during the two GATS period, there was VAT system, where in central and state taxes were imposed separately. Transportation costs from producing states to consuming states may result in price differences across states for the same brand.<sup>42</sup> Income disparities between states also influence price variation, as well as affordability among tobacco products across the states.<sup>21</sup> The percentage changes in retail price on bidis and cigarettes between the two GATS periods varied widely between states. For example, the price of 25 sticks of bidis was Rs 4.60 in West Bengal and Rs 7.6 in Tamil Nadu states during 2009/10, but in 2016/17 this was Rs 8.40 and Rs 21.50 respectively. Similarly, the price of 10 sticks of cigarettes was Rs13.30 in Haryana state and Rs23.40 in Gujarat state during 2009/10, but in 2016/17 this was Rs 69.00 and Rs51.80 respectively.<sup>21</sup> In our study, these

state-level and time period differences had a significant impact on the changes in current cigarette smoking but not for bidi smoking across states. Previous studies by Abdulkader et al and Subramanian et al on the tobacco consumption pattern in various regions in India also demonstrated that tobacco control activities vary across the regions and between different states, and this variation contributes to different patterns of change in prevalence of smoking.<sup>43,44</sup>

Our study used retail prices which do not account for inflation or income growth. This was due to lack of data to estimate affordability (i.e. the percentage of income required to buy specific units of bidis or cigarettes), which adjusts for the consumer's purchasing power, and is thereby considered an important indicator of the impact of tobacco-control fiscal policies.<sup>21</sup> Nevertheless, tobacco product retail prices are a major economic determinant of tobacco demand; and our study provides empirical evidence to underscore the fact that increasing prices without taking income growth into account might not lead to the desired effect of reduction in smoking prevalence.<sup>21,17</sup>

For the purpose of analysis, we defined and calculated a single standard unit price. In reality, however, there are a variety of products and brands available for both bidis and cigarettes with different sizes. It is possible that users of certain size or brand might be more sensitive to price change than those of the other and our analyses would have missed this difference. As our sample was drawn from GATS, it was naturally limited by the sample selection criteria of the survey. For instance, we might have missed migrant population due to the criterion of living in the address prior to the survey date. Since the GATS involves data of individuals above the age of 15 years, we could not draw any conclusion regarding those under 15 years old who might be more sensitive to price change. The data on our outcome of interest, current smoking status, was retrieved from an existing source of GATS where it is collected through self-report. There is a social desirability bias when self-reporting behaviours such as smoking, especially among females, which could lead to under-reporting and therefore estimation errors. Dual smokers of bidi and cigarettes were not considered for analysis because of differences in retail price of bidi and cigarettes. However, only ~1.4% of observations in our dataset were dual smokers of bidis and cigarettes. The interaction between the various background characteristics with the states could not be explored due to singularities in the model estimation. The CPI-IW database did not include data on retail prices of tobacco products from the following states which were therefore excluded from analysis: Jammu & Kashmir, Uttarakhand, Sikkim, Arunachal Pradesh, Nagaland, Manipur, Mizoram and Meghalaya. Cigarettes are sold in length that varies from 55 mm to 85 mm, but data in majority of states is only available for cigarettes of shorter than 69 mm length. We also did not include smokeless tobacco in our analysis. These limitations have an impact on the generalizability of our findings.

To the best of our knowledge, our study is the first to assess the association between the retail price of manufactured cigarettes and bidis and current smoking status in India, taking into account state-level variations to fit into India's national context. This study was conducted using large dataset from high-quality sources, which increases confidence in the validity of the results. The linking of two national representative surveys with the price of the tobacco products over the survey period, is to the best of our knowledge a novel approach. Future studies could explore the impact of the Goods and Services Tax (GST) implemented in 2017 on the use of the different tobacco products; as well as the impact of retail prices on the use of smokeless tobacco products, which are the predominant type of tobacco products used in India. This would facilitate policy making and strengthening of tobacco control across all

tobacco products, which will result in improvements in the health of general population in India.

## Conclusion

Our study suggests that current increase in the retail prices of smoked tobacco products in India seem to have an impact on manufactured cigarette use but not bidi use. This highlights the need for tobacco product tax increase that are sufficient to make all tobacco products less affordable and reduce their use. This is particularly so for bidis, which have remained more affordable at lower increments in tax as compared to cigarettes. In addition, eliminating the tax exemptions for small producers, which are often exploited by bidi producers, could reduce their affordability and use.
