# AN EFFICIENT MOVING PSEUDO-BOUNDARY MFS FOR VOID DETECTION 

ANDREAS KARAGEORGHIS, DANIEL LESNIC, AND LIVIU MARIN

#### Abstract

We consider the method of fundamental solutions (MFS) for the determination of the boundary of a void. In the proposed formulation the location of the pseudo-boundary is not fixed. The MFS discretization of the corresponding inverse geometric boundary value problem yields a system of nonlinear equations in which the coefficients in the MFS approximation, the discrete radii in the polar parametrization, the coordinates of the centre of the void and the expansion and dilation coefficients of the pseudo-boundaries are unknown. For the minimization of the resulting functional we employ the nonlinear least squares minimization routine lsqnonlin from the MATLAB ${ }^{\circledR}$ optimization toolbox. In contrast to previous studies, we exploit the option which enables the user to provide the analytical expression for the Jacobian of the system, and show that, although tedious, this leads to spectacular savings in computational time. The case of multiple voids is also addressed.

## 1. Introduction

When a mathematical model is governed by a partial differential equation (PDE) which possesses a fundamental solution available explicitly, the underlying solution can be represented in terms of a single-layer or a double-layer potential (or a combination of these). Although this formulation reduces the dimensionality of the problem by one, the boundary integrals involved become singular when they are collocated at a boundary point in order to impose the given boundary conditions. One way to deal with this is to de-singularise them by shifting the integral over the boundary to that over a fictitious pseudo-boundary embracing the solution domain in its interior [12], provided that the smoothness of the data and geometry are sufficient to allow an analytic continuation of the field to the pseudo-boundary, [25]. The resulting method is nowadays known as the method of fundamental solutions (MFS) which has become a versatile, easy to use and accurate meshless numerical method for solving a wide range of both direct and inverse problems [8, 18], and, in particular, inverse geometric problems [19]. These latter problems are difficult to solve because they are both nonlinear and ill-posed. Nonlinear optimization techniques including regularization are therefore necessary.
In a previous study [16], we considered similar inverse boundary value problems (BVPs) to the ones studied in the current work. We used the MATLAB ${ }^{\circledR}$ optimization toolbox routine lsqnonlin without exploiting the option which enables the user to provide the analytical expression for the

[^0]Jacobian of the system, which is calculated approximately internally. Note that the Jacobian in the context of the application of the MFS to nonlinear BVPs using lsqnonlin was provided in [10]. Problems similar to those considered in the current work were studied with the boundary function method in [23, 27].

## 2. MATHEMATICAL FORMULATION

A physical problem to which the MFS is most naturally suited and its application advantageous consists of the geometrical identification of an unknown void $\Omega_{1}$ compactly contained and concealed in a surrounding container $\Omega_{2}$ from non-destructive measurements on the boundary $\partial \Omega_{2}$ of the container. The process of scanning is based on electrostatics or steady-state heat conduction for which the governing PDE is the Laplace equation

$$
\begin{equation*}
\Delta u=0 \quad \text { in } \quad \Omega:=\Omega_{2} \backslash \Omega_{1}, \tag{2.1a}
\end{equation*}
$$

for the electrical potential or steady-state temperature $u$. In the above the annular material $\Omega \subset \mathbb{R}^{\mathrm{n}}, \mathrm{n}=2,3$, is assumed homogeneous, but anisotropic, nonlinear, layered or functionally graded materials are also feasible in the context of the MFS [3, 21].
In the investigation of this paper, the unknown void $\Omega_{1}$ is a rigid inclusion, on whose boundary the homogeneous Dirichlet boundary condition

$$
\begin{equation*}
u=0 \quad \text { on } \quad \partial \Omega_{1} \tag{2.1b}
\end{equation*}
$$

applies, or a cavity, on whose boundary the homogeneous Neumann boundary condition

$$
\begin{equation*}
\partial_{n} u=0 \quad \text { on } \quad \partial \Omega_{1} \tag{2.1c}
\end{equation*}
$$

applies, where $\boldsymbol{n}$ is the outward unit normal vector. Composite materials of different finite conductivity such that the void $\Omega_{1}$ is an unknown inclusion can also be considered [15]. We can unify the boundary conditions (2.1b) and (2.1c) into a single boundary condition written as

$$
\begin{equation*}
\alpha u+(1-\alpha) \partial_{n} u=0 \quad \text { on } \quad \partial \Omega_{1}, \quad \text { where } \quad \alpha \in\{0,1\} . \tag{2.1d}
\end{equation*}
$$

On the boundary $\partial \Omega_{2}$ of the container $\Omega_{2}$, any type of boundary condition can be prescribed, e.g. Dirichlet

$$
\begin{equation*}
u=f \quad \text { on } \quad \partial \Omega_{2}, \tag{2.1e}
\end{equation*}
$$

or Neumann

$$
\begin{equation*}
\partial_{n} u=g \quad \text { on } \quad \partial \Omega_{2} . \tag{2.1f}
\end{equation*}
$$

When $\alpha=0$, for (2.1a), (2.1d) and (2.1f) to be consistent, we require

$$
\begin{equation*}
\int_{\partial \Omega_{2}} g d s=0 \tag{2.2}
\end{equation*}
$$

We assume that the annular solution domain $\Omega=\Omega_{2} \backslash \Omega_{1}$ is connected and that its boundary $\partial \Omega=\partial \Omega_{1} \cup \partial \Omega_{2}$ is sufficiently smooth, e.g. of class $\mathcal{C}^{2}$. Then, if $\Omega_{1}$ is known, the direct linear and well-posed problem given by equations (2.1a), (2.1d) and (2.1e) (or (2.1f) and (2.2)) has a unique weak solution $u \in H^{1}(\Omega)$ if $f \in H^{1 / 2}\left(\partial \Omega_{2}\right)$ (or if $g \in H^{-1 / 2}\left(\partial \Omega_{2}\right)$ ), and a unique classical solution
$u \in \mathcal{C}^{2}(\Omega) \cap \mathcal{C}(\bar{\Omega})$, if $f$ (or $g$ ) is sufficiently smooth, see e.g. [26].
In contrast to the direct (forward) problem, where $\Omega_{1}$ is known, the resulting inverse nonlinear and ill-posed problem consists of determining the pair ( $u, \Omega_{1}$ ) satisfying the Laplace equation (2.1a), given the Dirichlet data $f \not \equiv$ constant in (2.1e), the homogeneous boundary condition (2.1d) and the Neumann current flux measurement (2.1f). Although the solution is unique, see [1, 11, 24], it is unstable with respect to small errors in the input Cauchy data (2.1e) and (2.1f).

## 3. The method of fundamental solutions (MFS)

Consider, for simplicity, two-dimensions [16] but similar considerations can be applied to threedimensions [17] as well. In the application of the MFS to the Laplace equation (2.1a), the solution is approximated by a linear combination of fundamental solutions [14]

$$
\begin{equation*}
u_{N}(\boldsymbol{c}, \boldsymbol{\xi} ; \boldsymbol{x})=\sum_{k=1}^{2 N} c_{k} G\left(\boldsymbol{\xi}_{k}, \boldsymbol{x}\right), \quad \boldsymbol{x} \in \bar{\Omega}, \tag{3.1}
\end{equation*}
$$

where $G$ is the fundamental solution of the two-dimensional Laplace operator, given by

$$
\begin{equation*}
G(\boldsymbol{\xi}, \boldsymbol{x})=-\frac{1}{2 \pi} \ln |\boldsymbol{\xi}-\boldsymbol{x}| . \tag{3.2}
\end{equation*}
$$

Note that throughout the paper we adopt the notation $\overline{1, \mathcal{N}}=1, \ldots, \mathcal{N}$. In this formulation, a total of $2 N$ sources $\left(\boldsymbol{\xi}_{k}\right)_{k=\overline{1,2 N}}$ are placed outside the domain $\Omega$, i.e. in $\Omega_{1} \cup\left(\mathbb{R}^{2} \backslash \bar{\Omega}_{2}\right)$. The first $N$ of these sources, $\left(\boldsymbol{\xi}_{k}\right)_{k=\overline{1, N}}$, are placed in $\Omega_{1}$, on a pseudo-boundary $\partial \Omega_{1}^{\prime}$ similar to $\partial \Omega_{1}$. By similar we mean a dilation or a contraction of a given star-like boundary about its centre. The remaining $N$ sources $\left(\boldsymbol{\xi}_{k}\right)_{k=\overline{N+1,2 N}}$ are placed in $\mathbb{R}^{2} \backslash \bar{\Omega}_{2}$, on a pseudo-boundary $\partial \Omega_{2}^{\prime}$ similar to $\partial \Omega_{2}$. A typical distribution of sources is depicted in Figure 1. It should be stated that in the current approach the two pseudo-boundaries $\partial \Omega_{1}^{\prime}$ and $\partial \Omega_{2}^{\prime}$ are not fixed and their final locations will be determined as part of the solution (moving pseudo-boundaries). The idea of taking similar pseudo-boundaries to the physical boundaries yields, in general, more accurate MFS results [9, 20].
In the current study, we shall take, for simplicity, the exterior boundary $\partial \Omega_{2}$ to be a circle of radius $R$, hence the sources on $\partial \Omega_{2}^{\prime}$ will be

$$
\begin{equation*}
\boldsymbol{\xi}_{N+k}=\eta_{\mathrm{ext}} R\left(\cos \vartheta_{k}, \sin \vartheta_{k}\right), \quad \vartheta_{k}=\frac{2 \pi(k-1)}{N}, \quad k=\overline{1, N} \tag{3.3}
\end{equation*}
$$

and the unknown dilation parameter $\eta_{\text {ext }}$ will lie in the interval $(1, S)$ with $S>1$ prescribed. We shall also assume that the unknown boundary $\partial \Omega_{1}$ is a smooth, star-like curve with respect to the centre coordinates $(X, Y)$ which are also unknown. Hence, in polar coordinates the equation of $\partial \Omega_{1}$ is

$$
\begin{equation*}
x=X+r(\vartheta) \cos \vartheta, \quad y=Y+r(\vartheta) \sin \vartheta, \quad \vartheta \in[0,2 \pi) \tag{3.4}
\end{equation*}
$$

where $r$ is a smooth $2 \pi$-periodic function. By denoting

$$
\begin{equation*}
r_{k}=r\left(\vartheta_{k}\right), \quad k=\overline{1, N} \tag{3.5}
\end{equation*}
$$

Figure 1. Geometry of problem with (a) One inclusion. (b) Two inclusions. The crosses $(+)$ denote the sources.
the source points on $\partial \Omega_{1}^{\prime}$ will be

$$
\begin{equation*}
\boldsymbol{\xi}_{k}=(X, Y)+\eta_{\mathrm{int}} r_{k}\left(\cos \vartheta_{k}, \sin \vartheta_{k}\right), \quad k=\overline{1, N} \tag{3.6}
\end{equation*}
$$

where the unknown contraction parameter $\eta_{\text {int }}$ lies in the interval $(0,1)$. In addition to the sources we shall also define $M+N$ boundary collocation points. The first $N$ of these, $\left(\boldsymbol{x}_{k}\right)_{k=\overline{1, N}}$ will be placed on $\partial \Omega_{1}$, as follows:

$$
\begin{equation*}
\boldsymbol{x}_{k}=(X, Y)+r_{k}\left(\cos \vartheta_{k}, \sin \vartheta_{k}\right), \quad k=\overline{1, N} . \tag{3.7}
\end{equation*}
$$

The remaining $M$ points $\left(\boldsymbol{x}_{N+\ell}\right)_{\ell=\overline{1, M}}$ will be placed on $\partial \Omega_{2}$, i.e.

$$
\begin{equation*}
\boldsymbol{x}_{N+\ell}=R\left(\cos \tilde{\vartheta}_{\ell}, \sin \tilde{\vartheta}_{\ell}\right), \quad \ell=\overline{1, M}, \quad \tilde{\vartheta}_{\ell}=\frac{2 \pi(\ell-1)}{M}, \quad \ell=\overline{1, M} . \tag{3.8}
\end{equation*}
$$

## 4. Implementation details

In the MFS formulation for the solution of inverse problem given by equations (2.1a), (2.1e), (2.1d) and (2.1f), described in Section 3, we have the following unknowns:

- The coefficients $\boldsymbol{c}=\left(c_{k}\right)_{k=\overline{1,2 N}}$ in (3.1),
- the radii $\boldsymbol{r}=\left(r_{k}\right)_{k=\overline{1, N}}$ in (3.5),
- the contraction and dilation coefficients $\boldsymbol{\eta}=\left(\eta_{\text {int }}, \eta_{\text {ext }}\right)$ in (3.6) and (3.3), and
- the centre coordinates $\boldsymbol{C}=(X, Y)$.

The unknowns listed above are determined from the imposition of the boundary conditions (2.1e), (2.1d) and (2.1f) in a least-squares sense which leads to minimizing the functional

$$
\begin{align*}
& S(\boldsymbol{c}, \boldsymbol{r}, \boldsymbol{\eta}, \boldsymbol{C}):=\sum_{j=N+1}^{N+M}\left[u_{N}\left(\boldsymbol{c}, \boldsymbol{\xi} ; \boldsymbol{x}_{j}\right)-f\left(\boldsymbol{x}_{j}\right)\right]^{2}+\sum_{j=N+1}^{N+M}\left[\partial_{n} u_{N}\left(\boldsymbol{c}, \boldsymbol{\xi} ; \boldsymbol{x}_{j}\right)-g^{\varepsilon}\left(\boldsymbol{x}_{j}\right)\right]^{2} \\
& \quad+\sum_{j=1}^{N}\left[\alpha u_{N}\left(\boldsymbol{c}, \boldsymbol{\xi} ; \boldsymbol{x}_{j}\right)+(1-\alpha) \partial_{n} u_{N}\left(\boldsymbol{c}, \boldsymbol{\xi} ; \boldsymbol{x}_{j}\right)\right]^{2}+\lambda_{1}|\boldsymbol{c}|^{2}+\lambda_{2} \sum_{\ell=2}^{N}\left(r_{\ell}-r_{\ell-1}\right)^{2} \tag{4.1}
\end{align*}
$$

where $\lambda_{1}$ and $\lambda_{2} \geq 0$ are regularization parameters that need to be prescribed and

$$
\begin{equation*}
g^{\varepsilon}\left(\boldsymbol{x}_{j}\right)=\left(1+\rho_{j} p\right) g\left(\boldsymbol{x}_{j}\right), \quad j=\overline{N+1, N+M}, \tag{4.2}
\end{equation*}
$$

where $p$ represents the percentage of noise added to the Neumann boundary data on $\partial \Omega_{2}$ and $\rho_{j}$ is a pseudo-random noisy variable drawn from a uniform distribution in $[-1,1]$ using the MATLAB ${ }^{\circledR}$ command $-1+2 *$ rand $(1, M)$. The outward normal vector $\boldsymbol{n}$ to the boundary, needed in the implementation of the method is defined in the Appendix. The regularization terms $\lambda_{1}|\boldsymbol{c}|^{2}$ and $\lambda_{2} \sum_{\ell=2}^{N}\left(r_{\ell}-r_{\ell-1}\right)^{2}$ have been added to the functional (4.1) to stabilize the MFS solution $u_{N}$ and the $\mathcal{C}^{1}$-smooth boundary $\partial \Omega_{1}$. The summation in the last term of (4.1) has been taken from $\ell=2$ to $N$ in order to compare with the numerical results of [16], which considered the same expression. The summation can also be taken from $\ell=2$ to $N+1$, with the convention that $r_{N+1}=r_{1}$, as considered in [4]. Finally, note that in (4.1) we have $3 N+4$ unknowns and $N+2 M$ boundary collocations equations so we need to take $M \geq N+2$.
4.1. Non-linear minimization software. In the current study, the least-squares minimization of functional (4.1) is achieved via the MATLAB ${ }^{\circledR}[22]$ optimization toolbox routine 1 sqnonlin. This, minimizes the general functional (cf. (4.1))

$$
\begin{equation*}
S(\mathbf{x}):=\sum_{j=1}^{\mathcal{J}} F_{j}^{2} \tag{4.3}
\end{equation*}
$$

with respect to the $\mathcal{M}$ unknowns $\mathbf{x}=\left[\mathrm{x}_{1}, \mathrm{x}_{2}, \ldots, \mathrm{x}_{\mathcal{M}}\right]^{\mathrm{T}}$.
The routine lsqnonlin by default uses the trust-region-reflective algorithm based on the interiorreflective Newton method [6,7] for minimizing the non-linear least-squares functional (4.3) starting from an initial guess $\mathbf{x}_{0}$. In the call to lsqnonlin, one is required to provide the functions $F_{j}$, $j=\overline{1, \mathcal{J}}$, in the functional (4.3). The user is also offered, via the optimization options, the choice of providing the Jacobian of the system analytically or not. In the latter case, the Jacobian is calculated internally. Otherwise, the exact Jacobian $J$ is

$$
J_{j, m}=\frac{\partial F_{j}}{\partial \mathrm{x}_{m}}, \quad j=\overline{1, \mathcal{J}}, m=\overline{1, \mathcal{M}}
$$

When the Jacobian is not provided, the optimization options are called with
options=optimoptions(@1sqnonlin, 'Display','iter', 'MaxFunEvals',mf, ...
'MaxIter',mm,'TolFun',1.E-15,'TolX',1.E-15,'SpecifyObjectiveGradient',false) and the function call is
[x,resnorm,residual, exitflag,output] = lsqnonlin(@f1, x0,options), where the function $\mathrm{f}=\mathrm{f} 1(\mathrm{x})$ provides the functions $F_{j}, j=\overline{1, \mathcal{J}}$.

When the exact Jacobian is provided, the optimization options are changed to options=optimoptions(@lsqnonlin, 'Display','iter', 'MaxFunEvals', mf , ... 'MaxIter', mm, 'TolFun',1.E-15, 'TolX',1.E-15, 'SpecifyObjectiveGradient',true), while the function call becomes function $[\mathrm{f}, \mathrm{J}]=\mathrm{f} 1(\mathrm{x})$, which provides both the functions $F_{j}, j=\overline{1, \mathcal{J}},(\mathrm{f})$, and the exact Jacobian $J_{j, m}, j=\overline{1, \mathcal{J}}, m=\overline{1, \mathcal{M}}$, (J).

The routine lsqnonlin terminates when

- the change in the solution vector $\mathbf{x}$ is less than the optimization options specified tolerance TolX, or
- the change in the residual is less than the optimization options specified tolerance TolFun, or
- the number of iterations MaxIter or the number of function evaluations MaxFunEvals (both specified in the optimization options) is exceeded.

Moreover, in lsqnonlin one has the option of imposing lower and upper bounds on the elements of the vector of unknowns $\mathbf{x}=[\boldsymbol{c}, \boldsymbol{r}, \boldsymbol{\eta}, \boldsymbol{C}]^{\mathrm{T}}$ through the user-specified vectors lb and up. In our applications, we imposed the constraints $0<r_{n}<R, \quad n=\overline{1, N}, 0<\eta_{\text {int }}<1,1<\eta_{\text {ext }}<4$ and $-R<X<R,-R<Y<R$.
4.2. Derivation of Jacobian. Some of the formulæ given below require the normal $\boldsymbol{n}_{j}=$ $\left(n_{x_{j}}, n_{y_{j}}\right), j=\overline{1, N}$, to the cavity boundary, which are provided in the Appendix. Moreover, the derivatives of the normals $\boldsymbol{n}_{j}$ with respect to the variables $r_{m}, m=\overline{1, N}$ are also provided in the Appendix. In the implementation we need to provide lsqnonlin with the following information (note that we use the notation $\gamma=-\frac{1}{2 \pi}$ ):
$\alpha=1$.

$$
\begin{gathered}
F_{j}=\sum_{k=1}^{2 N} c_{k} G\left(\boldsymbol{\xi}_{k}, \boldsymbol{x}_{j}\right)=\gamma \sum_{k=1}^{N} c_{k} \log \sqrt{\left(r_{j} \cos \vartheta_{j}-\eta_{\text {int }} r_{k} \cos \vartheta_{k}\right)^{2}+\left(r_{j} \sin \vartheta_{j}-\eta_{\mathrm{int}} r_{k} \sin \vartheta_{k}\right)^{2}} \\
+\gamma \sum_{k=N+1}^{2 N} c_{k} \log \sqrt{\left(X+r_{j} \cos \vartheta_{j}-\eta_{\mathrm{ext}} R \cos \vartheta_{k-N}\right)^{2}+\left(Y+r_{j} \sin \vartheta_{j}-\eta_{\mathrm{ext}} R \sin \vartheta_{k-N}\right)^{2}}, \quad j=\overline{1, N},
\end{gathered}
$$

$$
J_{j, m}=G\left(\boldsymbol{\xi}_{m}, \boldsymbol{x}_{j}\right), \quad j=\overline{1, N}, m=\overline{1,2 N}
$$

$$
\begin{gathered}
J_{j, 2 N+m}=\frac{\partial}{\partial r_{m}} \sum_{k=1}^{2 N} c_{k} G\left(\boldsymbol{\xi}_{k}, \boldsymbol{x}_{j}\right) \\
=-\gamma \eta_{\text {int }} c_{m} \frac{\left(\boldsymbol{x}_{j}-\boldsymbol{\xi}_{m}\right) \cdot\left(\cos \vartheta_{m}, \sin \vartheta_{m}\right)}{\left|\boldsymbol{x}_{j}-\boldsymbol{\xi}_{m}\right|^{2}}, \quad m \neq j, \quad j=\overline{1, N}, m=\overline{1, N}, \\
J_{m, 2 N+m}=\frac{\partial}{\partial r_{m}} \sum_{k=1}^{2 N} c_{k} G\left(\boldsymbol{\xi}_{k}, \boldsymbol{x}_{j}\right) \\
=-\gamma \eta_{\text {int }} c_{m} \frac{\left(\boldsymbol{x}_{m}-\boldsymbol{\xi}_{m}\right) \cdot\left(\cos \vartheta_{m}, \sin \vartheta_{m}\right)}{\left|\boldsymbol{x}_{m}-\boldsymbol{\xi}_{m}\right|^{2}}+\gamma \sum_{k=1}^{2 N} c_{k} \frac{\left(\boldsymbol{x}_{m}-\boldsymbol{\xi}_{k}\right) \cdot\left(\cos \vartheta_{m}, \sin \vartheta_{m}\right)}{\left|\boldsymbol{x}_{m}-\boldsymbol{\xi}_{k}\right|^{2}}, \quad m=\overline{1, N}, \\
J_{j, 3 N+1}=\sum_{k=1}^{2 N} c_{k} \frac{\partial G\left(\boldsymbol{\xi}_{k}, \boldsymbol{x}_{j}\right)}{\partial \eta_{\text {int }}}=-\gamma \sum_{k=1}^{N} c_{k} r_{k} \frac{\left(\boldsymbol{x}_{j}-\boldsymbol{\xi}_{k}\right) \cdot\left(\cos \vartheta_{k}, \sin \vartheta_{k}\right)}{\left|\boldsymbol{x}_{j}-\boldsymbol{\xi}_{k}\right|^{2}}, \quad j=\overline{1, N}, \\
J_{j, 3 N+2}=\sum_{k=1}^{2 N} c_{k} \frac{\partial G\left(\boldsymbol{\xi}_{k}, \boldsymbol{x}_{j}\right)}{\partial \eta_{\text {ext }}}=-\gamma \sum_{k=N+1}^{2 N} c_{k} R \frac{\left(\boldsymbol{x}_{j}-\boldsymbol{\xi}_{k}\right) \cdot\left(\cos \vartheta_{k-N}, \sin \vartheta_{k-N}\right)}{\left|\boldsymbol{x}_{j}-\boldsymbol{\xi}_{k}\right|^{2}}, \quad j=\overline{1, N}, \\
J_{j, 3 N+3}=\sum_{k=1}^{2 N} c_{k} \frac{\partial G\left(\boldsymbol{\xi}_{k}, \boldsymbol{x}_{j}\right)}{\partial X}=\gamma \sum_{k=N+1}^{2 N} c_{k} \frac{\left(\boldsymbol{x}_{j}-\boldsymbol{\xi}_{k}\right)_{x}}{\left|\boldsymbol{x}_{j}-\boldsymbol{\xi}_{k}\right|^{2}}, \quad j=\overline{1, N}, \\
J_{j, 3 N+4}=\sum_{k=1}^{2 N} c_{k} \frac{\partial G\left(\boldsymbol{\xi}_{k}, \boldsymbol{x}_{j}\right)}{\partial Y}=\gamma \sum_{k=N+1}^{2 N} c_{k} \frac{\left(\boldsymbol{x}_{j}-\boldsymbol{\xi}_{k}\right)_{y}}{\left|\boldsymbol{x}_{j}-\boldsymbol{\xi}_{k}\right|^{2}}, \quad j=\overline{1, N} .
\end{gathered}
$$

$$
\begin{aligned}
& \alpha=0 . \\
& \alpha=0 \text {. } \\

## 5. Numerical examples

In all examples considered in this study we have taken the outer boundary $\partial \Omega_{2}$ to be a circle of radius $R=1$, whilst the choice of the regularization parameters $\lambda_{1}$ and $\lambda_{2}$ is based on trial and error. However, one would expect that more sophisticated methods of selecting the regularization parameters will lead to even better reconstructions, see e.g. [2,5]. Nonetheless, this is beyond the scope of this investigation since one of our main aims herein is to emphasize the fact that both regularizing terms occurring in functional (4.1) are important and each yields a stabilised/regularized solution to the missing inner boundary that is exempted from high oscillations.
5.1. Example 1. Here we consider reconstructing a circular rigid inclusion with boundary $\partial \Omega_{1}$ of radius 0.5 in the case where $X=Y=0$ and $\alpha=1$ in (2.1d). The Dirichlet data (2.1e) on $\partial \Omega_{2}$ is taken as [13],

$$
\begin{equation*}
u(1, \vartheta)=f(\vartheta)=\mathrm{e}^{-\cos ^{2} \vartheta}, \quad \vartheta \in[0,2 \pi) \tag{5.1}
\end{equation*}
$$

The Neumann data (2.1f) is simulated by solving the direct mixed well-posed boundary value problem (2.1a), (2.1b) and (5.1), using the MFS with $M=N=400$ and $\eta_{\text {int }}=0.8, \eta_{\text {ext }}=1.2$. In order to avoid committing an inverse crime, the inverse solver is applied using $N=56, M=64$. We choose the initial vector of unknowns $\mathbf{x}_{0}=\left(\boldsymbol{c}_{0}, \boldsymbol{r}_{0}, \eta_{\text {int }}^{0}, \eta_{\mathrm{ext}}^{0}, X_{0}, Y_{0}\right)^{\mathrm{T}}=(\mathbf{0}, \mathbf{0 . 1}, 0.3,2,-0.3,0.25)^{\mathrm{T}}$. In Table 1 we present the CPU times required for the above parameters for different numbers of iterations when providing and when not providing the Jacobian. The savings when providing the Jacobian are spectacular.
In Figure 2 we present the reduction of the residual functional (4.1) after 100 iterations with no noise and no regularization when providing the Jacobian and when not providing the Jacobian. As can be observed, when providing the Jacobian the residual decreases much faster.

Figure 2. Example 1: Residual functional (4.1) with number of iterations, no noise and no regularization.

In Figure 3 we present the results obtained for different numbers of iterations, with no noise and no regularization, i.e. $\lambda_{1}=\lambda_{2}=0$. It can be seen that the solution becomes accurate after about 20 iterations.
In Figures 4 and 5 we present the reconstructed curves with noise level of $10 \%$ after 1000 iterations and various regularization parameters $\lambda_{1}$ when $\lambda_{2}=0$, and $\lambda_{2}$ when $\lambda_{1}=0$, respectively. From these figures it can be seen that the inclusion of regularization, either with $\lambda_{1}$ or $\lambda_{2}$, yields stable numerical solutions. In Figure 5 it is clear that as $\lambda_{2}$ increases, the reconstruction tends to a circle (of radius 0.5), due to the fact that the distribution of points $\left(\mathbf{x}_{k}\right)_{k=\overline{1, N}}$ that minimize the distance between them (which is what $\lambda_{2}$ penalises) is an equally-spaced distribution of points over a circumference. In this way, a high $\lambda_{2}$ seems to be an advantage in the case of circular voids. On the contrary, this a drawback for other domains, as will be further illustrated later in Figure 8 for the (non-circular) bean-shaped void (5.2). Moreover, it seems that regularizing the boundary $\partial \Omega_{1}$ is less sensitive to the choice of the regularization parameter $\lambda_{2}$ (in between $10^{-2}$ and $10^{2}$ ) than is regularizing the solution $u$ (i.e. the vector of coefficients $\boldsymbol{c}$ ) through the regularization parameter $\lambda_{1}=10^{-5}$.
5.2. Example 2. We consider a bean-shaped rigid inclusion whose boundary $\partial \Omega_{1}$ is described by $X=0.2, Y=0.3$, and the radial parametrization

$$
\begin{equation*}
r(\vartheta)=0.6\left(\frac{0.5+0.4 \cos (\vartheta)+0.1 \sin (2 \vartheta)}{1+0.7 \cos (\vartheta)}\right), \quad \vartheta \in[0,2 \pi), \tag{5.2}
\end{equation*}
$$

Figure 3. Example 1: Results for various numbers of iterations, no noise and no regularization.
in the case of $\alpha=1$ in (2.1d). This example, which was also considered in [13], is more difficult than Example 1 because of the presence of a sharp cusp-like portion mimicking a re-entrant corner. The Neumann data (2.1f) is simulated by solving the direct mixed well-posed boundary value problem (2.1a), (2.1b) and (5.1), when $\partial \Omega_{1}$ is given by (5.2), using the MFS with $M=N=400$ and $\eta_{\text {int }}=0.8, \eta_{\text {ext }}=1.2$. In order to avoid committing an inverse crime, the inverse solver is applied using $N=56, M=64$. We choose the initial vector of unknowns $\mathbf{x}_{0}=\left(\boldsymbol{c}_{0}, \boldsymbol{r}_{0}, \eta_{\text {int }}^{0}, \eta_{\text {ext }}^{0}, X_{0}, Y_{0}\right)^{\mathrm{T}}=$ $(\mathbf{0}, \mathbf{0 . 1}, 0.3,2,0.1,0)^{\mathrm{T}}$.
In Figure 6 we present the results obtained for different numbers of iterations, with no noise and no regularization, i.e. $\lambda_{1}=\lambda_{2}=0$. From these figures it can be seen that the solution becomes quite accurate after about 100 iterations.
In Figures 7 and 8 we present the reconstructed curves with noise level of $5 \%$ after 1000 iterations and various regularization parameters $\lambda_{1}$ when $\lambda_{2}=0$, and $\lambda_{2}$ when $\lambda_{1}=0$, respectively. From these figures it can be seen that the inclusion of regularization, either with $\lambda_{1}$ or $\lambda_{2}$, yields stable numerical solutions.

Figure 4. Example 1: Results for noise $p=10 \%$ and regularization with $\lambda_{1}$.
5.3. Example 3. We consider an example for which the exact solution is known. Here we consider reconstructing a circular cavity (i.e. $\alpha=0$ in (2.1d)) centred at the origin $(X, Y)=(0,0)$. In particular, we consider

$$
\begin{equation*}
\Omega_{1}=\left\{(x, y) \in \mathbb{R}^{2}: x^{2}+y^{2}<R_{0}^{2}<1\right\}, \quad \Omega_{2}=\left\{(x, y) \in \mathbb{R}^{2}: x^{2}+y^{2}<1\right\} \tag{5.3}
\end{equation*}
$$

and

$$
\begin{equation*}
u(x, y)=\frac{x}{R_{0}^{2}}+\frac{x}{x^{2}+y^{2}} \tag{5.4}
\end{equation*}
$$

For any $0<R_{0}<1$, the function $u$ satisfies equations (2.1a), (2.1c), (2.1e) and (2.1f), with

$$
\begin{equation*}
f(x, y)=x\left(\frac{1}{R_{0}^{2}}+1\right) \quad \text { and } \quad g(x, y)=x\left(\frac{1}{R_{0}^{2}}-1\right), \quad(x, y) \in \partial \Omega_{2} \tag{5.5}
\end{equation*}
$$

Note that the compatibility condition (2.2) on the Neumann flux data $g$ is automatically satisfied.
In our numerical experiments we consider $R_{0}=0.5$. We choose the initial vector of unknowns $\mathbf{x}_{0}=\left(\boldsymbol{c}_{0}, \boldsymbol{r}_{0}, \eta_{\text {int }}^{0}, \eta_{\text {ext }}^{0}, X_{0}, Y_{0}\right)^{\mathrm{T}}=(\mathbf{0}, \mathbf{0 . 1}, 0.1,2,-0.1,0.5)^{\mathrm{T}}$.

Figure 5. Example 1: Results for noise $p=10 \%$ and regularization with $\lambda_{2}$.
In Figure 9 we present the results obtained for different numbers of iterations, with no noise and no regularization, i.e. $\lambda_{1}=\lambda_{2}=0$. From these figures it can be seen that the solution becomes quite accurate after about 20 iterations.
In Figures 10 and 11 we present the reconstructed curves with noise level of $5 \%$ after 1000 iterations and various regularization parameters $\lambda_{1}$ when $\lambda_{2}=0$, and $\lambda_{2}$ when $\lambda_{1}=0$, respectively. From these figures it can be seen that the inclusion of regularization, either with $\lambda_{1}$ or $\lambda_{2}$, yields stable numerical solutions.
5.4. Example 4. We consider a bean-shaped cavity (i.e. $\alpha=0$ in (2.1d)) whose boundary $\partial \Omega_{1}$ is described by $X=0.2, Y=0.3$, and the radial parametrization (5.2). The numerical details are the same as those of Example 2, except for the initial guess which is taken $\mathbf{x}_{0}=\left(\boldsymbol{c}_{0}, \boldsymbol{r}_{0}, \eta_{\text {int }}^{0}, \eta_{\text {ext }}^{0}, X_{0}, Y_{0}\right)^{\mathrm{T}}=(\mathbf{0}, \mathbf{0 . 2 5}, 0.3,2,-0.2,-0.2)^{\mathrm{T}}$.
In Figure 12 we present the results obtained for different numbers of iterations, with no noise and no regularization, i.e. $\lambda_{1}=\lambda_{2}=0$. From these figures it can be seen that the solution becomes quite accurate after about 1000 iterations.

Figure 6. Example 2: Results for various numbers of iterations, no noise and no regularization.
In Figures 13 and 14 we present the reconstructed curves with noise level of $5 \%$ after 1000 iterations and various regularization parameters $\lambda_{1}$ when $\lambda_{2}=0$, and $\lambda_{2}$ when $\lambda_{1}=0$, respectively. From these figures it can be seen that the inclusion of regularization, either with $\lambda_{1}$ or $\lambda_{2}$, yields stable numerical solutions.

## 6. Extension to multiple voids

We now extend the MFS formulation for one void, described in Sections 3 and 4, to the case of two voids given by

$$
\begin{equation*}
\Delta u=0 \quad \text { in } \Omega \tag{6.1a}
\end{equation*}
$$

subject to

$$
\begin{gather*}
u=f \quad \text { on } \partial \Omega_{2},  \tag{6.1b}\\
\partial_{n} u=g \quad \text { on } \partial \Omega_{2},  \tag{6.1c}\\
\alpha_{1} u+\left(1-\alpha_{1}\right) \partial_{n} u=0 \quad \text { on } \partial \Omega_{1}^{a}, \quad \text { where } \quad \alpha_{1} \in\{0,1\}, \tag{6.1d}
\end{gather*}
$$

Figure 7. Example 2: Results for noise $p=5 \%$ and regularization with $\lambda_{1}$.
and

$$
\begin{equation*}
\alpha_{2} u+\left(1-\alpha_{2}\right) \partial_{n} u=0 \quad \text { on } \partial \Omega_{1}^{b}, \quad \text { where } \quad \alpha_{2} \in\{0,1\} . \tag{6.1e}
\end{equation*}
$$

Here $\Omega_{1}^{a}$ and $\Omega_{1}^{b}$ are two disjoint voids, such that $\Omega_{1}^{a} \cup \Omega_{1}^{b}=\Omega_{1}$ and $\bar{\Omega}_{1}^{a} \cap \bar{\Omega}_{1}^{b}=\emptyset$, see Figure 1.
The MFS approximation of the solution of inverse boundary value problem (6.1) is

$$
\begin{equation*}
u_{N}(\boldsymbol{c}, \boldsymbol{\xi} ; \boldsymbol{x})=\sum_{k=1}^{3 N} c_{k} G\left(\boldsymbol{\xi}_{k}, \boldsymbol{x}\right), \quad \boldsymbol{x} \in \bar{\Omega} \tag{6.2}
\end{equation*}
$$

In this case $3 N$ sources $\left(\boldsymbol{\xi}_{k}\right)_{k=\overline{1,3 N}}$ are placed outside $\Omega$, that is in $\Omega_{1} \cup\left(\mathbb{R}^{2} \backslash \bar{\Omega}_{2}\right)$. The first $N$ sources $\left(\boldsymbol{\xi}_{k}\right)_{k=\overline{1, N}}$ are placed in $\Omega_{1}^{a}$ on a pseudo-boundary $\partial \Omega_{1}^{a \prime}$ similar to $\partial \Omega_{1}^{a}$. The next $N$ sources $\left(\boldsymbol{\xi}_{k}\right)_{k=\overline{N+1,2 N}}$ are placed in $\Omega_{1}^{b}$ on a pseudo-boundary $\partial \Omega_{1}^{b^{\prime}}$ similar to $\partial \Omega_{1}^{b}$. Finally, the remaining $N$ sources $\left(\boldsymbol{\xi}_{k}\right)_{k=\overline{2 N+1,3 N}}$ are placed in $\mathbb{R}^{2} \backslash \bar{\Omega}_{2}$ on a pseudo-boundary $\partial \Omega_{2}^{\prime}$ similar (dilation) to $\partial \Omega_{2}$. Note that the first two pseudo-boundaries are contractions with unknown contraction coefficients $\eta_{\text {int }}^{a} \in(0,1)$ and $\eta_{\text {int }}^{b} \in(0,1)$, respectively, while the third pseudo-boundary is a dilation with

Figure 8. Example 2: Results for noise $p=5 \%$ and regularization with $\lambda_{2}$.
contraction coefficient $\eta_{\text {ext }} \in(1, S)$ with $S>1$ prescribed.
We assume that the unknown boundaries $\partial \Omega_{1}^{a}$ and $\partial \Omega_{1}^{b}$ are a smooth, star-like curves with respect to their centres which have unknown coordinates $\left(X^{a}, Y^{a}\right)$ and $\left(X^{b}, Y^{b}\right)$, respectively. Their equations in polar coordinates are thus

$$
\begin{equation*}
(x, y)=\left(X^{a}+r^{a}(\vartheta) \cos \vartheta, Y^{a}+r^{a}(\vartheta) \sin \vartheta\right) \text { and }(x, y)=\left(X^{b}+r^{b}(\vartheta) \cos \vartheta, Y^{b}+r^{b}(\vartheta) \sin \vartheta\right) \tag{6.3}
\end{equation*}
$$

$\vartheta \in[0,2 \pi)$, respectively, where $r^{a}$ and $r^{b}$ are smooth $2 \pi$-periodic functions.
Using the notation

$$
\begin{equation*}
r_{k}=r_{k}^{a}=r^{a}\left(\vartheta_{k}\right), \quad r_{k+N}=r_{k}^{b}=r^{b}\left(\vartheta_{k}\right), \quad k=\overline{1, N} \tag{6.4}
\end{equation*}
$$

Figure 9. Example 3: Results for various numbers of iterations, no noise and no regularization. the sources are defined as follows:

$$
\begin{align*}
\boldsymbol{\xi}_{k} & =\left(X^{a}, Y^{a}\right)+\eta_{\mathrm{int}}^{a} r_{k}^{a}\left(\cos \vartheta_{k}, \sin \vartheta_{k}\right) \\
\boldsymbol{\xi}_{N+k} & =\left(X^{b}, Y^{b}\right)+\eta_{\mathrm{int}}^{b} r_{N+k}^{b}\left(\cos \vartheta_{k}, \sin \vartheta_{k}\right),  \tag{6.5}\\
\boldsymbol{\xi}_{2 N+k} & =\eta_{\mathrm{ext}} R\left(\cos \vartheta_{k}, \sin \vartheta_{k}\right), \quad k=\overline{1, N},
\end{align*}
$$

where $\vartheta_{k}=\frac{2 \pi(k-1)}{N}, k=\overline{1, N}$. In addition to the sources, we define $2 N+M$ boundary collocation points $\left(\boldsymbol{x}_{\ell}\right)_{\ell=\overline{1,2 N+M}}$ as follows:

$$
\begin{align*}
\boldsymbol{x}_{k} & =\left(X^{a}, Y^{a}\right)+r_{k}^{a}\left(\cos \vartheta_{k}, \sin \vartheta_{k}\right), \\
\boldsymbol{x}_{N+k} & =\left(X^{b}, Y^{b}\right)+r_{N+k}^{b}\left(\cos \vartheta_{k}, \sin \vartheta_{k}\right), \quad k=\overline{1, N},  \tag{6.6}\\
\boldsymbol{x}_{2 N+\ell} & =R\left(\cos \tilde{\vartheta}_{\ell}, \sin \tilde{\vartheta}_{\ell}\right), \quad \ell=\overline{1, M},
\end{align*}
$$

where $\tilde{\vartheta}_{\ell}=\frac{2 \pi(\ell-1)}{M}, \ell=\overline{1, M}$.

Figure 10. Example 3: Results for noise $p=5 \%$ and regularization with $\lambda_{1}$.
In the MFS formulation for the solution of inverse boundary value problem (6.1) we have the following unknowns:

- The coefficients $\left(c_{k}\right)_{k=\overline{1,3 N}}$ in (6.2),
- the radii $\left(r_{k}^{a}\right)_{k=\overline{1, N}},\left(r_{k}^{b}\right)_{k=\overline{1, N}}$ in (6.4),
- the contraction and dilation coefficients $\eta_{\text {int }}^{a}, \eta_{\text {int }}^{b}$ and $\eta_{\text {ext }}$, and
- the centre coordinates $\left(X^{a}, Y^{a}\right),\left(X^{b}, Y^{b}\right)$.

The unknowns listed above are determined by imposing the boundary conditions (6.1b)-(6.1e) in a least-squares sense by minimizing the functional

$$
\begin{aligned}
& S\left(\boldsymbol{c}, \boldsymbol{r}^{a}, \boldsymbol{r}^{b}, \boldsymbol{\eta}, \boldsymbol{C}\right):=\sum_{j=2 N+1}^{2 N+M}\left[u_{N}\left(\boldsymbol{c}, \boldsymbol{\xi} ; \boldsymbol{x}_{j}\right)-f\left(\boldsymbol{x}_{j}\right)\right]^{2}+\sum_{j=2 N+1}^{2 N+M}\left[\partial_{n} u_{N}\left(\boldsymbol{c}, \boldsymbol{\xi} ; \boldsymbol{x}_{j}\right)-g^{\varepsilon}\left(\boldsymbol{x}_{j}\right)\right]^{2} \\
&+\sum_{j=1}^{N}\left[\alpha_{1} u_{N}\left(\boldsymbol{c}, \boldsymbol{\xi} ; \boldsymbol{x}_{j}\right)+\left(1-\alpha_{1}\right) \partial_{n} u_{N}\left(\boldsymbol{c}, \boldsymbol{\xi} ; \boldsymbol{x}_{j}\right)\right]^{2}+\sum_{j=N+1}^{2 N}\left[\alpha_{2} u_{N}\left(\boldsymbol{c}, \boldsymbol{\xi} ; \boldsymbol{x}_{j}\right)+\left(1-\alpha_{2}\right) \partial_{n} u_{N}\left(\boldsymbol{c}, \boldsymbol{\xi} ; \boldsymbol{x}_{j}\right)\right]^{2}
\end{aligned}
$$

Figure 11. Example 3: Results for noise $p=5 \%$ and regularization with $\lambda_{2}$.

$$
\begin{equation*}
+\lambda_{1}|\boldsymbol{c}|^{2}+\lambda_{2}^{a} \sum_{\ell=2}^{N}\left(r_{\ell}^{a}-r_{\ell-1}^{a}\right)^{2}+\lambda_{2}^{b} \sum_{\ell=2}^{N}\left(r_{\ell}^{b}-r_{\ell-1}^{b}\right)^{2} \tag{6.7}
\end{equation*}
$$

where $\lambda_{1}, \lambda_{2}^{a}, \lambda_{2}^{b} \geq 0$ are regularization parameters to be prescribed, $\boldsymbol{c}=\left[c_{1}, c_{2}, \ldots, c_{3 N}\right]^{\mathrm{T}}$, $\boldsymbol{r}^{a}=\left[r_{1}^{a}, r_{2}^{a}, \ldots, r_{N}^{a}\right]^{\mathrm{T}}, \boldsymbol{r}^{b}=\left[r_{1}^{b}, r_{2}^{b}, \ldots, r_{N}^{b}\right]^{\mathrm{T}}, \boldsymbol{\eta}=\left[\eta_{\text {int }}^{a}, \eta_{\text {int }}^{b}, \eta_{\text {ext }}\right]^{\mathrm{T}}$ and $\boldsymbol{C}=\left[X^{a}, Y^{a}, X^{b}, Y^{b}\right]^{\mathrm{T}}$.
The number of unknowns is $5 N+7$ and the number of boundary collocation equations $2 N+2 M$, and thus we need to take $2 M \geq 3 N+7$.
6.1. Derivation of Jacobian. In the implementation we need to provide lsqnonlin with the following information (for simplicity we only consider the case $\alpha_{1}=\alpha_{2}=1 \mathrm{in}$ (6.1d) and (6.1e), respectively):

$$
F_{j}=\sum_{k=1}^{3 N} c_{k} G\left(\boldsymbol{\xi}_{k}, \boldsymbol{x}_{j}\right)=\gamma \sum_{k=1}^{N} c_{k} \log \sqrt{\left(r_{j} \cos \vartheta_{j}-\eta_{\mathrm{int}}^{a} r_{k} \cos \vartheta_{k}\right)^{2}+\left(r_{j} \sin \vartheta_{j}-\eta_{\mathrm{int}}^{a} r_{k} \sin \vartheta_{k}\right)^{2}}
$$

Figure 12. Example 4: Results for various numbers of iterations, no noise and no regularization.

$$
\begin{aligned}
& +\gamma \sum_{k=N+1}^{2 N} c_{k} \log \sqrt{\left(X^{a}+r_{j} \cos \vartheta_{j}-X^{b}-\eta_{\mathrm{int}}^{b} r_{k} \cos \vartheta_{k}\right)^{2}+\left(Y^{a}+r_{j} \sin \vartheta_{j}-Y^{b}-\eta_{\mathrm{int}}^{b} r_{k} \sin \vartheta_{k}\right)^{2}} \\
& +\gamma \sum_{k=2 N+1}^{3 N} c_{k} \log \sqrt{\left(X^{a}+r_{j} \cos \vartheta_{j}-\eta_{\mathrm{ext}} R \cos \vartheta_{k-2 N}\right)^{2}+\left(Y^{a}+r_{j} \sin \vartheta_{j}-\eta_{\mathrm{ext}} R \sin \vartheta_{k-2 N}\right)^{2}} \\
& j=\overline{1, N}
\end{aligned}
$$

\end{gathered}
$$

6.2. Example 5. We consider the case of a multiple void made up a bean-shaped obstacle $\Omega_{1}^{a}$ and a peanut-shaped obstacle $\Omega_{1}^{b}$ are present. The obstacle $\Omega_{1}^{a}$ is described by the radial parametrization

$$
\begin{equation*}
r^{a}(\vartheta)=0.5\left(\frac{0.5+0.4 \cos (\vartheta)+0.1 \sin (2 \vartheta)}{1+0.7 \cos (\vartheta)}\right), \quad \vartheta \in[0,2 \pi) \tag{6.8}
\end{equation*}
$$

while $\Omega_{1}^{b}$ is described by

$$
\begin{equation*}
r(\vartheta)=0.3 \sqrt{\cos ^{2}(\vartheta)+0.25 \sin ^{2}(\vartheta)}, \quad \vartheta \in[0,2 \pi) \tag{6.9}
\end{equation*}
$$

and have centres $X^{a}=-0.3, Y^{a}=0.3$ and $X^{b}=0.3, Y^{b}=-0.3$, respectively. In this example, we consider the homogeneous Dirichlet boundary conditions with $\alpha_{1}=\alpha_{2}=1$ on the boundaries of both rigid inclusions. The Neumann data (6.1c) is simulated by solving the direct boundary value problem (6.1) (without (6.1c) and with $f$ in (6.1b) given by (5.1)) using the MFS with $M=N=400$. In order to avoid committing an inverse crime, the inverse solver is applied using $N=40, M=125$. Moreover, we took the initial vector of unknowns $\mathbf{x}^{0}=\left(\boldsymbol{c}_{0}, \boldsymbol{r}_{0}^{a}, \boldsymbol{r}_{0}^{b}, \eta_{\text {int }}^{a^{0}}, \eta_{\text {int }}^{b^{0}}, \eta_{\text {ext }}^{0}, X_{0}^{a}, Y_{0}^{a}, X_{0}^{b}, Y_{0}^{b}\right)=(\mathbf{0}, \mathbf{0 . 1}, \mathbf{0 . 1}, 0.5,0.5,1.5,-0.5,0.2,0.5,-0.2)$.

In Table 2 we present the CPU times required for the above parameters for different numbers of iterations when providing and when not providing the Jacobian. The savings when providing the Jacobian are spectacular.

In Figure 15 we present the reduction of the residual after 500 iterations, no noise and no regularization, when providing the Jacobian and when not providing the Jacobian. As can be observed, when providing the Jacobian the residual functional (6.7) decreases faster than when the Jacobian is not provided.

Figure 15. Example 5: Residual functional (6.7) with the number of iterations.
In Figure 16 we present the results obtained for different numbers of iterations and no regularization. In Figures 17 and 18 we present the corresponding reconstructed curves with a noise level of $p=5 \%$, after 1000 iterations, and various levels of regularization $\lambda_{1}$ with $\lambda_{2}=\lambda_{2}^{a}=\lambda_{2}^{b}=0$, and $\lambda_{1}=0$ with $\lambda_{2}=\lambda_{2}^{a}=\lambda_{2}^{b}$, respectively. Overall, Figures 16-18 illustrate that the MFS can indeed retrieve successfully voids having two connected components.

## 7. Conclusions

In this study, we have investigated the performance of the MFS for the solution of inverse geometric problems governed by the Laplace equation. In particular, we have considered the problem of determining a rigid inclusion or a cavity. The MFS discretization led to a nonlinear system of equations for the coefficients in the MFS expansion, the radial radii, the contraction and dilation coefficients and the coordinates of the centre of the cavity. For the solution of the nonlinear system we have used the MATLAB ${ }^{\circledR}$ optimization toolbox routine lsqnonlin. In previous studies, such as [16], we had chosen the option of not providing the Jacobian of the system which was calculated internally. In the current work we do provide the Jacobian of the system and show that this leads to considerable savings in computational time, rapid convergence as well as accurate reconstructions of the unknown void. The method is extended to the case of two voids. In future studies we plan to investigate the corresponding application to three-dimensional problems.

Figure 16. Example 5: Results for various numbers of iterations for no noise and no regularization.

## Appendix

The outward normal vector $\boldsymbol{n}$ is defined as follows:
$\boldsymbol{n}=\left\{\begin{array}{cl}\cos \vartheta \mathbf{i}+\sin \vartheta \mathbf{j}, & \text { if } \boldsymbol{x} \in \partial \Omega_{2}, \\ \frac{1}{\sqrt{r^{2}(\vartheta)+r^{\prime 2}(\vartheta)}}\left[-\left(r^{\prime}(\vartheta) \sin \vartheta+r(\vartheta) \cos \vartheta\right) \mathbf{i}+\left(r^{\prime}(\vartheta) \cos \vartheta-r(\vartheta) \sin \vartheta\right) \mathbf{j}\right], & \text { if } \quad \boldsymbol{x} \in \partial \Omega_{1},\end{array}\right.$
where $\mathbf{i}=(1,0)$ and $\mathbf{j}=(0,1)$. As a result, from (3.1) the normal derivative $\partial_{n} u_{N}$ is evaluated as

$$
\begin{equation*}
\partial_{n} u_{N}=\boldsymbol{n} \cdot \nabla u_{N}=-\frac{1}{2 \pi} \sum_{k=1}^{2 N} c_{k} \frac{\left(\boldsymbol{x}-\boldsymbol{\xi}_{k}\right) \cdot \boldsymbol{n}}{\left|\boldsymbol{x}-\boldsymbol{\xi}_{k}\right|^{2}} . \tag{A.1}
\end{equation*}
$$

In the above expression, we use the finite-difference approximation

$$
\begin{equation*}
r^{\prime}\left(\vartheta_{j}\right) \approx \frac{r_{i+1}-r_{i-1}}{4 \pi / N}=r_{j}^{\prime}, \quad j=\overline{1, N}, \tag{A.2}
\end{equation*}
$$

with the convention that $r_{N+1}=r_{1}, r_{0}=r_{N}$, and

$$
\begin{gathered}
n_{x_{j}}=\frac{-\left(r^{\prime}\left(\vartheta_{j}\right) \sin \vartheta_{j}+r\left(\vartheta_{j}\right) \cos \vartheta_{j}\right)}{\sqrt{r^{2}\left(\vartheta_{j}\right)+r^{\prime 2}\left(\vartheta_{j}\right)}} \approx \frac{-\left(r_{j}^{\prime} S_{j}+r_{j} C_{j}\right)}{\sqrt{r_{j}^{2}+r_{j}^{\prime 2}}}=\frac{-\left(\frac{r_{j+1}-r_{j-1}}{\sigma}\right) S_{j}-r_{j} C_{j}}{\sqrt{r_{j}^{2}+\left(\frac{r_{j+1}-r_{j-1}}{\sigma}\right)^{2}}}, \\
n_{y_{j}}=\frac{r^{\prime}\left(\vartheta_{j}\right) \cos \vartheta_{j}-r\left(\vartheta_{j}\right) \sin \vartheta_{j}}{\sqrt{r^{2}\left(\vartheta_{j}\right)+r^{\prime 2}\left(\vartheta_{j}\right)}} \approx \frac{r_{j}^{\prime} C_{j}-r_{j} S_{j}}{\sqrt{r_{j}^{2}+r_{j}^{\prime 2}}}=\frac{\left(\frac{r_{j+1}-r_{j-1}}{\sigma}\right) C_{j}-r_{j} S_{j}}{\sqrt{r_{j}^{2}+\left(\frac{r_{j+1}-r_{j-1}}{\sigma}\right)^{2}}}
\end{gathered}
$$

where $j=\overline{1, N}$ and $\sigma=4 \pi / N$. Therefore,

$$
\begin{gathered}
n_{x_{1}}=\frac{-\left(\frac{r_{2}-r_{N}}{\sigma}\right) S_{1}-r_{1} C_{1}}{\sqrt{r_{1}^{2}+\left(\frac{r_{2}-r_{N}}{\sigma}\right)^{2}}} \\
n_{x_{j}}=\frac{-\left(\frac{r_{j+1}-r_{j-1}}{\sigma}\right) S_{j}-r_{j} C_{j}}{\sqrt{r_{j}^{2}+\left(\frac{\left.r_{j+1}-r_{j-1}\right)^{2}}{\sigma}\right.}, \quad j=\overline{2, N-1}},
\end{gathered}
$$

$$
\begin{gathered}
n_{x_{N}}=\frac{-\left(\frac{r_{1}-r_{N-1}}{\sigma}\right) S_{N}-r_{N} C_{N}}{\sqrt{r_{N}^{2}+\left(\frac{r_{1}-r_{N-1}}{\sigma}\right)^{2}}}, \\
n_{y_{j}}=\frac{\left(\frac{r_{2}-r_{N}}{\sigma}\right) C_{1}-r_{1} S_{1}}{\sqrt{r_{1}^{2}+\left(\frac{r_{2}-r_{N}}{\sigma}\right)^{2}}} \\
\sqrt{\frac{r_{j+1}-r_{j-1}}{\sigma} r_{j}^{2}+\left(\frac{r_{j+1}-r_{j-1} S_{j}^{2}}{\sigma}, j=2, N-1\right.} \\
n_{y_{N}}=\frac{\left(\frac{r_{1}-r_{N-1}}{\sigma}\right)^{2} C_{N}-r_{N} S_{N}}{\sqrt{r_{N}^{2}+\left(\frac{r_{1}-r_{N-1}}{\sigma}\right)^{2}}}
\end{gathered}
$$

In the derivation of the Jacobian we shall need the following derivatives:

$$
\begin{aligned}
& \frac{\partial n_{x_{j}}}{\partial r_{j}}=\frac{-C_{j}}{\sqrt{r_{j}^{2}+\left(\frac{r_{j+1}-r_{j-1}}{\sigma}\right)^{2}}}-\frac{\left(-\left(\frac{r_{j+1}-r_{j-1}}{\sigma}\right) S_{j}-r_{j} C_{j}\right) r_{j}}{\left(r_{j}^{2}+\left(\frac{r_{j+1}-r_{j-1}}{\sigma}\right)^{2}\right)^{3 / 2}}, j=\overline{1, N}, \\
& \frac{\partial n_{x_{j}}}{\partial r_{j+1}}=\frac{-\frac{S_{j}}{\sigma}}{\sqrt{r_{j}^{2}+\left(\frac{r_{j+1}-r_{j-1}}{\sigma}\right)^{2}}}-\frac{\left(-\left(\frac{r_{j+1}-r_{j-1}}{\sigma}\right) S_{j}-r_{j} C_{j}\right)\left(\frac{r_{j+1}-r_{j-1}}{\sigma^{2}}\right)}{\left(r_{j}^{2}+\left(\frac{r_{j+1}-r_{j-1}}{\sigma}\right)^{2}\right)^{3 / 2}}, j=\overline{1, N-1}, \\
& \frac{\partial n_{x_{N}}}{\partial r_{1}}=\frac{-\frac{S_{N}}{\sigma}}{\sqrt{r_{N}^{2}+\left(\frac{r_{1}-r_{N-1}}{\sigma}\right)^{2}}}-\frac{\left(-\left(\frac{r_{1}-r_{N-1}}{\sigma}\right) S_{N}-r_{N} C_{N}\right)\left(\frac{r_{1}-r_{N-1}}{\sigma^{2}}\right)}{\left(r_{N}^{2}+\left(\frac{r_{1}-r_{N-1}}{\sigma}\right)^{2}\right)^{3 / 2}}, \\
& \frac{\partial n_{x_{j}}}{\partial r_{j-1}}=\frac{\frac{S_{j}}{\sigma}}{\sqrt{r_{j}^{2}+\left(\frac{r_{j+1}-r_{j-1}}{\sigma}\right)^{2}}}-\frac{\left(\left(\frac{r_{j+1}-r_{j-1}}{\sigma}\right) S_{j}+r_{j} C_{j}\right)\left(\frac{r_{j+1}-r_{j-1}}{\sigma^{2}}\right)}{\left(r_{j}^{2}+\left(\frac{r_{j+1}-r_{j-1}}{\sigma}\right)^{2}\right)^{3 / 2}}, j=\overline{2, N}, \\
& \frac{\partial n_{x_{1}}}{\partial r_{N}}=\frac{\frac{S_{1}}{\sigma}}{\sqrt{r_{1}^{2}+\left(\frac{r_{2}-r_{N}}{\sigma}\right)^{2}}}-\frac{\left(\left(\frac{r_{2}-r_{N}}{\sigma}\right) S_{1}+r_{1} C_{1}\right)\left(\frac{r_{2}-r_{N}}{\sigma^{2}}\right)}{\left(r_{1}^{2}+\left(\frac{r_{2}-r_{N}}{\sigma}\right)^{2}\right)^{3 / 2}},
\end{aligned}
$$

and

$$
\begin{aligned}
& \frac{\partial n_{y_{j}}}{\partial r_{j}}=\frac{-S_{j}}{\sqrt{r_{j}^{2}+\left(\frac{r_{j+1}-r_{j-1}}{\sigma}\right)^{2}}}-\frac{\left(\left(\frac{r_{j+1}-r_{j-1}}{\sigma}\right) C_{j}-r_{j} S_{j}\right) r_{j}}{\left(r_{j}^{2}+\left(\frac{r_{j+1}-r_{j-1}}{\sigma}\right)^{2}\right)^{3 / 2}}, j=\overline{1, N}, \\
& \frac{\partial n_{y_{j}}}{\partial r_{j+1}}=\frac{\frac{C_{j}}{\sigma}}{\sqrt{r_{j}^{2}+\left(\frac{r_{j+1}-r_{j-1}}{\sigma}\right)^{2}}}-\frac{\left(\left(\frac{r_{j+1}-r_{j-1}}{\sigma}\right) C_{j}-r_{j} S_{j}\right)\left(\frac{r_{j+1}-r_{j-1}}{\sigma^{2}}\right)}{\left(r_{j}^{2}+\left(\frac{r_{j+1}-r_{j-1}}{\sigma}\right)^{2}\right)^{3 / 2}}, j=\overline{1, N-1}, \\
& \frac{\partial n_{y_{N}}}{\partial r_{1}}=\frac{\frac{C_{N}}{\sigma}}{\sqrt{r_{N}^{2}+\left(\frac{r_{1}-r_{N-1}}{\sigma}\right)^{2}}}-\frac{\left(\left(\frac{r_{1}-r_{N-1}}{\sigma}\right) C_{N}-r_{N} S_{N}\right)\left(\frac{r_{1}-r_{N-1}}{\sigma^{2}}\right)}{\left(r_{N}^{2}+\left(\frac{r_{1}-r_{N-1}}{\sigma}\right)^{2}\right)^{3 / 2}}, \\
& \frac{\partial n_{y_{j}}}{\partial r_{j-1}}=\frac{-\frac{C_{j}}{\sigma}}{\sqrt{r_{j}^{2}+\left(\frac{r_{j+1}-r_{j-1}}{\sigma}\right)^{2}}}+\frac{\left(\left(\frac{r_{j+1}-r_{j-1}}{\sigma}\right) C_{j}-r_{j} S_{j}\right)\left(\frac{r_{j+1}-r_{j-1}}{\sigma^{2}}\right)}{\left(r_{j}^{2}+\left(\frac{r_{j+1}-r_{j-1}}{\sigma}\right)^{2}\right)^{3 / 2}}, j=\overline{2, N}, \\
& \frac{\partial n_{y_{1}}}{\partial r_{N}}=\frac{-\frac{C_{1}}{\sigma}}{\sqrt{r_{1}^{2}+\left(\frac{r_{2}-r_{N}}{\sigma}\right)^{2}}}+\frac{\left(\left(\frac{r_{2}-r_{N}}{\sigma}\right) C_{1}-r_{1} S_{1}\right)\left(\frac{r_{2}-r_{N}}{\sigma^{2}}\right)}{\left(r_{1}^{2}+\left(\frac{r_{2}-r_{N}}{\sigma}\right)^{2}\right)^{3 / 2}} .
\end{aligned}
