Accessibility challenges for older adults in South Manchester: a capability approach

Elisha Henry and Gideon Baffoe

Department of Environment and Geography, University of York, York, UK

ABSTRACT

Accessibility is critical in achieving sustainable and equitable transport systems. This study investigates the accessibility of older adults, a group that has received little attention in the accessibility literature yet faces significant mobility barriers. Following qualitative approaches, including interviews and open-ended questionnaires, and employing the Accessibility as a Capability framework (AaaC) and Transport-Related Social Exclusion (TRSE) dimensions, the study analyses the opportunities and barriers older adults face in accessing transport systems in six wards of South Manchester. Results reveal the crucial role of individual abilities and perceptions in converting resources into access. Analysis of travel experiences showed that even when accessibility appears high, older adults may still expend a significant amount of effort to gain accessibility, particularly through emotional ‘work’ caused by transport-related fear and stress. The findings suggest a focus on the subjective aspects of travel to remove barriers to accessibility and improve access to valued capabilities while creating more equitable and sustainable transport systems.

Introduction

The 21st Century has seen two major population shifts in the shapes of urbanisation and an ageing population (Leeson 2018). Population projections estimate that the number of people aged 60 years and over will double by 2050 with more older people expected to live in cities (WHO 2015, 2018). These shifts present significant opportunities and challenges for the future. Although urbanisation can result in improved access to services and opportunities, this needs to be supported by the necessary infrastructure, welfare, and other provisions to ensure equitable outcomes and sustainable growth (Leeson, 2018). Population ageing is set to impact many sectors, including the economy, transport and land use (Ravensbergen et al. 2022). As such, transport systems need to be able to adapt to the ageing population to ensure the sustainability of cities and wider society.

The paramount goal of every transport policy is to improve accessibility to places, people and

services (van Wee et al. 2011; Miller 2018). Access is crucial for societal participation and maintenance of socioeconomic and cultural capital (Miller 2018; Middleton and Spinney 2019). Societies and individuals rely on transport to access everyday opportunities and these requirements change over one’s lifetime and in accordance with place of abode (Banister 2019). A lack of access to opportunities, therefore, suggests exclusion from society and factors such as low income, age and disability can exacerbate this problem (Lucas et al. 2016). Equity analysis has been considered in accessibility studies (van Wee et al. 2011; Vecchio et al. 2020), but only recently have researchers begun to specifically consider older adults’ access to opportunities (Ravensbergen et al. 2022). In light of an ageing population, this paper is timely as it will bring critical awareness in ensuring older adults can access opportunities to improve their well-being while enhancing their

active participation in society to keep cities thriving. This has long been recognised in the World Health Organisation's Global Age-friendly Cities guidance (WHO 2007) of which twelve UK cities are members.

Ageing remains a pressing social issue in the UK and despite policy commitments, little is known about individual experiences. Planning and policy have tended to focus on improving transport infrastructure rather than the opportunities that infrastructure might afford to local people (Abreu et al. 2022). Accessibility measures tend to objectively focus on the interaction between land use and transport (Ryan and Pereira 2021). However, the simple existence of a transport system does not guarantee accessibility (Johnson et al. 2017). There is growing literature support for approaches that consider equity and social inclusion and the independence, well-being, and quality of life of ageing people (Lin and Cui 2021; Abreu et al. 2022). Transport studies have largely focused on mapping travel behaviour and assumptions about decision-making and routing (Miller 2005). Qualitative investigation that seeks to address the heterogeneity of individuals, their travel behaviour and their potential, imagined, aspirational and emotive mobilities is lacking (Pankhurst et al. 2014). Such a study will help place older people's experiences at the centre of transport planning, thereby improving accessibility to opportunities. This paper aims to contribute empirical evidence to fill the existing gap.

The study aims to analyse the opportunities and barriers older adults face in accessing transport systems using South Manchester as a case study. The study draws on data from qualitative interview surveys and the Capability Approach (CA) to accessibility to understand the opportunities and barriers to mobility among older adults in South Manchester, UK. The study also employs the Accessibility as a Capability (AaaC) framework to analyse the processes by which the interaction between spatial resources and an individual's conversion function can limit or expand their capabilities.

The study is structured as follows. The next section reviews the relevant literature on travel, accessibility, and exclusion, drawing on the context of older adults in the UK. This is followed by the methodological approach, including the conceptual framework. The results are then presented, followed by a discussion and conclusion.

Literature review

Ageing and travel

Ageing is negatively correlated to mobility. As people age, their mobility level declines sharply, underscoring the need for a more accessible and inclusive built environment to accommodate their needs (DfT 2021). This becomes more urgent given that older adults have the desire to maintain independence and inclusion when it comes to travel (Musselwhite and Haddad 2010). Although older people are not a homogenous group with varied mobility and travel characteristics (Su and Bell 2009), individual and contextual factors determine mobility needs. At the individual level, gender, education, employment status, income, residential location and household characteristics are the major factors influencing older adults' travel patterns (Cui et al. 2016). Declining physical and mental health and increased frailty, on the other hand, reduce older adults' mobility (Glass 2003). Contextual factors include the transport system and land use, as well as the policy landscape. Evidence shows that as people transition into later life, they undertake fewer daily trips and travel shorter distances (Páez et al. 2007). For this group, work-related trips decrease while medical, social and shopping-related trips increase (Titheridge et al. 2009; Cui et al. 2016). Engaging in social activity is particularly important for well-being and plays a major role in later life when established networks diminish (Middleton and Spinney 2019). Studies have also shown that older adults do not always travel for functional needs but also for recreation, such as viewing scenery, visiting new places and having chance encounters (Musselwhite and Haddad 2010). These aspects are likely to be missed in quantitative travel studies focusing solely on functional travel.

Conceptualising mobility and accessibility

Mobility is the ability to move from one place to another and often reflects the frequency of movements and trips made with a purpose (Plazinić and Jović 2018). Some scholars go beyond this definition of 'realised' mobility, to 'potential' mobility, which incorporates accessibility, motility, opportunities and capabilities (Flamm and Kaufmann 2006; Nordbakke 2013). This paper draws on 'realised' mobility and views it as an important element of accessibility but also acknowledges that a lack of mobility does not

necessarily cause a lack of access. This understanding of mobility is compatible with the general understanding in gerontology: a person's purposeful movement through the environment, which includes forms of transportation (Stalvey et al. 1999). Although researching mobility is important as it holds the potential to facilitate access, transport planning has largely concentrated on accessibility (van Wee et al. 2011; Miller 2018).

Accessibility conceptualisation tends to combine two aspects: the options to reach certain destinations and the resistance to travel (van Wee 2016). It is widely defined as 'the extent to which land-use and transport systems enable (groups of) individuals to reach activities or destinations by means of a (combination of) transport mode(s)' (Geurs and van Wee 2004, p. 128). Accessibility forms the basis for assessing the performance of transport systems in a region (Boisjoly and El-Geneidy 2017). Individual characteristics, including income, age, gender, disability and race (Geurs and van Wee 2004), provide a social perspective on transport planning (Lucas 2012). This perspective is important as it has generated debates around the influence of transport on social exclusion, social equity and sustainability (Lucas 2012).

In recent times, accessibility has been framed in terms of capabilities (Vecchio and Martens 2021; Luz and Portugal 2022). This provides impetus for the application of the capability approach (CA) in studying transport accessibility. Middleton and Spinney (2019) argue that accessibility studies often focus on the 'objective' causes of (in)accessibility, as opposed to the actual experiences of being mobile and gaining accessibility. The authors argue that research should focus on the 'emotional work' involved in gaining accessibility, and the adaptations individuals undertake to perform in a transport system that does not serve them (Middleton and Spinney 2019). Banister (2019) calls for a 'softer' approach to accessibility, moving away from the exclusive focus on the materialistic and functional aspects of travel to open up opportunities. This 'softer' approach involves measuring perceptions, preferences, experiences and barriers (Banister 2019; Tiznado-Aitken et al. 2020). As a response, however, scholars are increasingly pointing to the potential of 'well-being' based approaches to address the subjective experiences of accessibility, including the CA (Banister 2019; Vecchio and Martens 2021; Luz and Portugal 2022). The CA offers a stronger

theoretical basis than traditional transport approaches as it allows the inclusion of subjective factors that shape accessibility (Nordbakke 2013). It accounts for the wide diversity of individuals' characteristics, opportunities and choices (Vecchio and Martens 2021). Meanwhile, its people-centeredness provides opportunities to improve social equity, social inclusion and sustainability.

Social exclusion and transport

Social exclusion is largely viewed as relational, focusing on exclusionary processes rather than simply labelling a group as excluded (Popay 2010). Individuals are said to be situated on a multidimensional continuum of inclusion/exclusion characterised by the unjust distribution of resources, capabilities and rights (Silver 2007; Popay 2010). Social exclusion highlights the processes of unequal access to participation in society (Kenyon et al. 2002). Although all the excluded have the preference to be included, they are in most cases prevented by barriers beyond their control (van Wee et al. 2011). Exclusion policy tends to focus on educational and labour market concerns, which inevitably neglects the needs of the aged (Scharf 2015). Yet, the impact and prevalence of social exclusion are often amplified by old age (Walsh et al. 2017), underscoring the need to consider the processes by which older adults may become excluded from society.

For people who do not own a car, bus usage tends to increase in later life, especially in countries that provide concessionary passes (Musselwhite 2017). Yet, older people still face many barriers to access. Scholars note that issues around physical accessibility, safety, a lack of information, a lack of suitable equipment and furniture and staff are unhelpful to their needs (Musselwhite 2017). Understanding the barriers that older adults face in using public transport can, therefore, decrease car dependency and improve accessibility.

Even though it is difficult to say in an absolute sense whether a person is socially excluded and if this is caused by accessibility (Titheridge et al., 2009), the concern here is about the processes of transport-related social exclusion (TRSE). Previous studies have determined several dimensions of TRSE, comprising physical, economic, temporal, spatial, and psychological exclusion from facilities. Yigitcanlar et al. (2018) proposed an informational dimension, to account for

travel-related information availability. Benevenuto and Caulfield (2019) introduced the social-position dimension to account for restriction based on one's social position (e.g. gender, race, age, and ethnicity). Luz and Portugal (2022) proposed a combination of all the aforementioned dimensions of TRSE and added 'digital divide' exclusion to account for difficulties using or accessing ICT and the internet, which is crucial with the rise of smart mobility (Groth 2019). This paper attempts to shed light on the barriers to accessibility faced by older adults using Luz and Portugal's (2022) TRSE dimensions (see Appendix 1). The processes, actions, and decisions that lead to social exclusion have to be given particular attention to transport research in order to promote just and equitable cities (Lucas 2012).

Methodology

Context

Older adults in the UK are largely car-dependent. Evidence suggests that apart from health and locational factors that require people to drive, the dependence reflects the failure of the UK's transport systems to cater for their needs (Holley-Moore and Creighton 2015). Addressing these failings is crucial and the Department for Transport (DfT) recognises that high car dependency is not sustainable in growing metropolitan areas (DfT 2019). Accessibility planning in the UK is based on assessing whether 'people are physically and financially able to access transport' (SEU 2003, p. 1). The UK government publishes annual statistics on transport use (National Statistics 2022), yet the Office for Statistics Regulation found that statistics are currently not answering the key questions of those with an interest in accessibility (OfSR 2022). Travel statistics are based on modelled journey times which makes it hard to assess the effect of individual and household characteristics which leads to a lack of access and social exclusion (Lucas et al. 2016). More specifically, the DfT indicators are not suitable for evaluating the needs of older people as they do not reflect their purpose, attitudes and aspirations towards travel (Titheridge et al., 2009). Although accessibility is clearly on the UK transport agenda, the widely held view is that an approach solely based on physical and financial accessibility may be incomplete. Currently, older adults who give up driving suffer a reduction in health and well-being and an increase

in stress and social isolation (Musselwhite and Haddad 2010). Giving up driving can also increase the likelihood of social exclusion (Cui et al. 2016). Therefore, accessible public transport and special transport services become important for those with more complex mobility needs. This study is timely as it will provide empirical evidence to shape the transport needs for older adults in the UK.

The growing interest in social exclusion has generated debate around its linkage to transport. The relationship was first established in the UK Social Exclusion Unit's report 'Making the Connections: Final Report of Transport and Social Exclusion' (SEU 2003). The report introduced statutory accessibility audits into Local Transport Plans in England and Wales, involving aggregate measures based on average travel time to essential destinations. Since then, the interaction between accessibility, transport and social exclusion and its effect on accessibility has been explored (Farrington 2007). Greater Manchester has Greater Manchester Accessibility Levels (GMAL) to measure the accessibility of a certain point to transport provisions, considering walk access time and service availability (TfGM 2016). However, these indicators say nothing about what individuals can access given their unique sets of circumstances (Titheridge et al., 2009), including age, gender, disability, and ethnicity. Preston and Rajé (2007) found that measures that account for these factors, still homogenise groups and lose the richness of individuals' lived experiences and the multidimensional nature of exclusion. This clearly calls for a study that considers the actual exclusionary experiences of specific groups.

Conceptual frameworks: the capability approach (CA) and accessibility as a capability (AaaC) framework

The Capability Approach (CA) focuses on individual freedom and its close association with achievement and well-being (Sen 1999). The CA represents a fundamental shift from conventional utilitarian approaches that focus on a person's resources, to a focus on their capabilities. It sees human beings and their well-being as the 'end' or objective of development rather than economic growth (Alkire 2007), focusing on what they achieve instead of utility. The approach consists of four main concepts: resources, individual 'conversion function', functioning, and capabilities. Resources are the commodities and intangible goods available to a person and are considered

a ‘means to achievement’ (Sen 1992, p. 33). The individual conversion function is the ability to convert resources into capabilities. Functioning is the ‘various things a person may value doing or being’ with realised functioning, representing what a person achieves and how (Sen 1999, p. 75). Capabilities are the ‘alternative combinations of beings and doings that are feasible to achieve’ and entail real opportunities that are available for people to do and be (Sen 1999, p. 75).

Well-being is achieved through both functioning and capabilities. While capabilities represent the various opportunities available to a person, functioning are those capabilities the individual chooses to realise and achieve. Therefore, individual freedom and choice are central to the CA (Nussbaum and Sen 1993). Sen (1992) makes clear that capabilities must be valued by the individual to achieve freedom and well-being. Social systems should be evaluated according to the extent of freedom people have to achieve the functioning they value (Alkire 2002). This paper follows this line of thought and evaluates the urban transport system on its ability to allow people to achieve desired functioning.

Although the operationalisation of the CA in transport geography is still in the infancy stage, it is fast gaining traction as an alternative approach to transport and accessibility analysis (Nordbakke 2013; Hickman et al. 2017; Bantis and Haworth 2020; Vecchio 2020). Past studies have utilised Nussbaum’s 10 central capabilities (see Nussbaum 2000, 2009). Nussbaum argues that ‘their list of capabilities has universal appeal, and they are important for any demographic group (Nussbaum 2000). This study aims to allow older adults to express what they value, avoiding assumptions and generalisations. As such, the central capabilities will be used to frame the discussion and emphasise capabilities that are not met.

Scholars have conceptualised accessibility as a capability (AaaC) (Vecchio and Martens 2021; Luz and Portugal 2022). This framing considers how an individual builds and appropriates the possibility of being mobile and accessing valued opportunities (Figure 1) (Vecchio and Martens 2021). Luz and Portugal (2022) illustrate how when the interaction between spatial resources and the individual’s conversion function limits an individual’s capabilities, manifesting in the form of barriers. These barriers

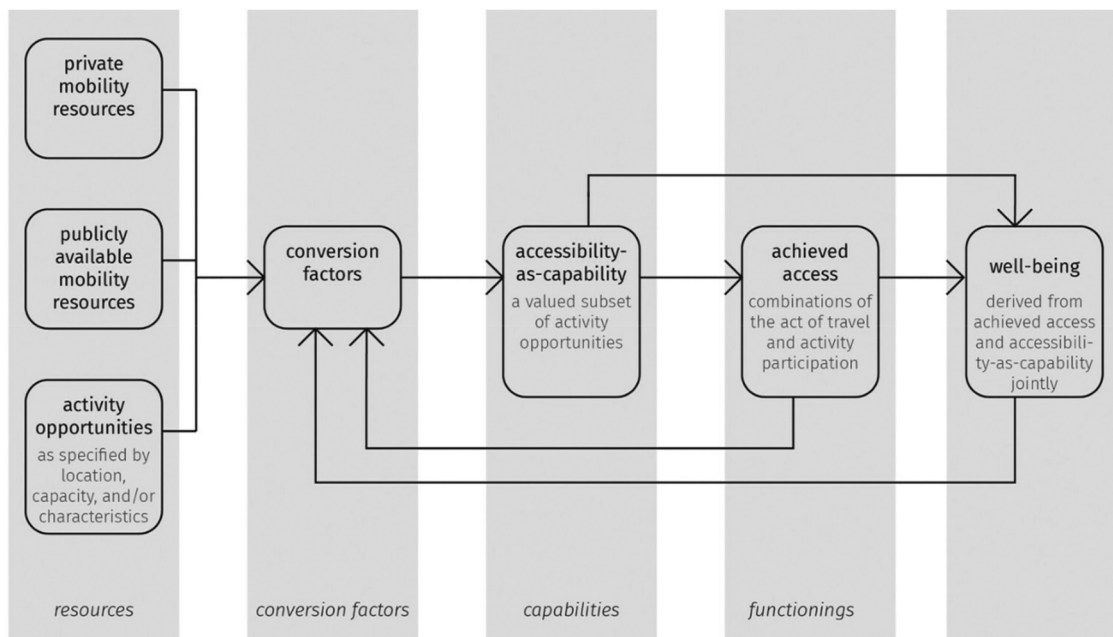

Figure 1. Accessibility as a capability framework (AaaC). Source: Vecchio and Martens (2021).

can create systematic problems in accessing opportunities and can lead to TRSE as discussed previously. Sen argues that evaluations and policies should focus on removing barriers so that individuals have more freedom to live what they value (Robeyns 2005). Clearly, identifying barriers to accessibility is crucial to understanding how they can be removed. This study contributes to a more comprehensive understanding of these barriers. We argue that removing barriers will expand the capability set that is associated with functioning and ultimately well-being, thereby improving the social inclusion of older adults.

Research approach

This paper utilises a mixed-method approach. To gather data on AaaC, Vecchio and Martens (2021) recommend combining a top-down aggregate component on addressing transport systems and land use and a bottom-up component shedding light on conversion factors (also known as conversion function and used interchangeably in this paper) through an individual understanding of mobility. For the top-down element, secondary data from Transport for Greater Manchester's (2016) Accessibility Levels (GMAL) is used. The contribution of this paper is the bottom-up element where the qualitative approach is used for understanding complex notions like freedom and opportunities that are core to the CA framework. To assess TRSE, we use a qualitative approach to understand the individual and grassroots perspectives of those who experience exclusion (Lucas 2019). Open-response questionnaires and semi-structured interviews were used to gather the qualitative data.

Data collection

A questionnaire survey was used in gathering empirical data. An open-response questionnaire was used to gather information about participants' characteristics, perceptions, thoughts and experiences. Open-ended questions were designed to allow participants to recount experiences, perceptions and opinions in their own way (McGuirk and O'Neill 2016). The questionnaire data was triangulated with interviews. A semi-structured interview asked follow-up questions on emerging issues from the questionnaire while understanding participants' subjective travel experiences. A total of 26 participants responded to

the open-ended questionnaires while 5 interviews were conducted.

The questionnaire data was used in conjunction with secondary data from Transport for Greater Manchester's Accessibility Levels (GMAL), which provides data on participants' spatial resources using postcodes. GMAL scores any location within the Greater Manchester region from 1 to 8 depending on the density of public transport provision (bus, metro and rail), considering access times and average wait times (TfGM 2016). A score of 1 represents very low accessibility, while a score of 8 represents very high accessibility (see Appendix 2). GMAL is weighed towards the most accessible transport service, assuming it will be the mode of preference.

Participants recruitment

Questionnaires and interviews were carried out with older adults (60+), who live in the three areas of South Manchester, and who either did not have a driver's licence or owned a road vehicle at the time of the research. The specificity of the sample allowed involves a relatively small number of participants, assuming that it would be sufficient to grasp the capabilities and functioning relevant to those who meet the criteria. The study areas were selected as they contained the highest proportion of the over 66 age group in the southern region of Greater Manchester and were characterised by at least 1.5% population growth of this age group by 2031 (Wall 2021). The three study areas, each made up of two electoral wards, were Chorlton and Chorlton Park, Didsbury East and Didsbury West, and Sharston and Northenden.

Participants were recruited through two pathways. Non-probabilistic sampling is often inevitable in studying specific or hard-to-reach populations (Wellington and Szczerbinski 2007). Therefore, an opportunistic sampling method was used by advertising the survey through local community groups on social media. Secondly, participants were recruited using a guided sampling technique using stakeholders from local community groups who facilitated access to the desired participants. Involving stakeholders or 'gatekeepers', is often essential in the recruitment of older adults as it increases trust and rapport and can facilitate access to especially hard-to-reach populations (Weil et al. 2017).

Questionnaires were completed in February and March 2023. The in-person questionnaires were handed out to a local community group after a short presentation on the project. Participants of both online and in-person questionnaires were required to read and acknowledge the participant information and consent forms for ethical purposes. The questionnaire finished by asking participants if they would like to participate in a follow-up interview, which took place in March 2023 over the phone and email exchanges (one participant). Interviews were audio recorded with the consent of the participants and then transcribed, removing personal identification data to ensure complete anonymity.

Data analysis

The interview data was transcribed and imported into NVivo together with the open-ended questionnaire data for analysis. A qualitative content was then applied. Coding was used to deduce the components of AaaC and TRSE. The categorised data was then reduced analytically to identify and highlight the most relevant and meaningful patterns in the data.

Results

Table 1 provides an overview of the residential and household characteristics of the study participants. The sample is weighted towards females and Chorlton residents which appeared to be the main

demographic of the charity, where 17 of the questionnaires were completed. It was targeted to complete more than five interviews, yet retention of participants proved difficult, potentially due to research fatigue or uncertainty about the value of their participation. The main results are laid out in two parts: the first section follows the components of AaaC, and the second part addresses the TRSE dimensions.

Mobility resources

The participants' mobility resources (i.e. the public transport available to them) were assessed by scoring postcodes against GMAL. Postcodes ranged between 4 and 6 with an average of 5. According to GMAL (see Appendix 2), participants have an average to high 'accessibility' to public transport resources. In terms of mode, all postcodes showed access to the bus service, with 65% having access to the metro. Only one postcode had access to a train. In terms of private resources, some participants expressed they had access to charity-provided transport resources, access to lifts in family and friend's vehicles (social resources) and taxi services. These available resources define how mobile and frequent participants move around in Manchester and beyond.

Conversion function

Ability

As expected, participants' abilities varied. Participants were split in terms of describing good mobility or poor mobility. While some mentioned they could only walk for a short length of time, others reported using walking aids such as rollators, trolleys, walking poles and sticks. Although not explicitly asked, participants also mentioned health issues, including problems with hearing and eyesight, and cognitive and psychological issues that affect their ability to travel. These abilities define what the participants can do on their own or with the help of mobility aids.

Perceptions

When considering the public transport system in its entirety, people's perceptions were largely positive. Respondents mentioned the range of transport modes available to them and how this provides opportunities to travel locally and further afield. Respondents remarked as:

Table 1. Sociodemographic characteristics of study participants (n = 26).

Characteristic	Number

Source: Field survey 2023.

You can always rely on public transport. You can catch the tram to the outskirts of Manchester, and you can catch a bus all over the place. (Male, Chorlton)

My area has good transport links for local and further trips. (Female, Didsbury)

Several participants expressed that they felt lucky with the public transport options available to them, and compared their resource provision potentially worse off in some areas:

Yes, we are very lucky. We have good public transport, we have a metro, we have got buses. I know we are very lucky, a lot of places don't have public transport. (Female, Chorlton)

However, perceptions of individual transport modes varied. Perceptions of the Metro (tram) were largely positive. People expressed that they 'liked' and 'loved' the tram and described it as 'excellent', 'brilliant', 'accessible', 'reliable', 'clean', 'safe' and 'on-time', but that destinations were sometimes limited. Perceptions of the buses were mixed with some describing the service as 'good', 'reasonable' and 'satisfactory'; but many had negative perceptions, with participants describing them as a 'nightmare', 'inconsistent', 'old', 'crowded' and 'not comfortable', with journeys that are 'slow' and 'too long'. Some participants felt that the bus services had deteriorated in recent years. It is noted that bus services may have been cut since GMAL was published.

Since revamped a few years ago, many services have been cut, making it very difficult to get to appointments ... the local estate bus is being cut meaning a 10/15-minute walk to the other bus. (Female, Chorlton)

Among the few participants who mentioned the train, there was a consensus that local trains were unreliable due to frequent cancellations. In terms of active travel, perceptions were generally positive, and participants mentioned a variety of routes specifically for walking that are available to them. However, participants felt that the pavements were unsafe and difficult to navigate.

The interaction between resources and the conversion function

Responses revealed that mobility appeared to be a significant factor in determining individuals' interaction with resources. For example, two female participants (Table 2) from Chorlton with different levels of mobility had different perceptions of the resources available to them:

The respondent with poor mobility relied on private transport resources (lifts with friends and taxis), which appeared to be common among those who described poor mobility. Perceptions also shaped participants' interactions with resources. Despite nearly all participants having the highest access to bus services according to GMAL, people appeared to use the tram due to favourable perceptions.

I only use the bus to access parts that I cannot get to on the tram. I prefer the tram because it's clean, reliable, and safe. (Female, Chorlton)

As soon as the tram was built, that was it, I never used the bus. And the same with other people, as soon as the trams were built, they stopped using the buses. (Male, Chorlton)

It can be seen that participants' ability and perceptions shape their interaction with the transport system. Functioning further reveals how the interaction between conversion factors and resources shapes achieved access.

Functioning

Participants mentioned an average of 3 places or activities they travel to in a typical week. Shopping was the most cited achieved access, followed by community groups, towns, the city centre, and areas of green space. The most frequent travel mode was the metro, followed by the bus. A good proportion of the participants used private transport modes, and several participants travelled actively. This provides insight into the main reasons why older adults travel within and outside Manchester.

Table 2. Participants interaction between mobility and perceptions of resources.

Female, Chorlton. Good Mobility	Female, Chorlton. Poor Mobility (requires rollator)
Perception of public transport: "Positive. There are plenty of buses."	Perception of public transport: "Very negative. The bus stop is too far away ... with my mobility, it's an effort."
Perception of active travel: "Yes. I am lucky to have pleasant walks along the Mersey."	Perception of active travel: "No. The pavements are in a deplorable state which is very off-putting"

Source: Field survey 2023.

Capabilities

Participants were asked about places and activities they value being able to access, even if they do so infrequently. It emerged that they value being able to travel to a variety of places inside and outside of Manchester, including towns and cities, the countryside, natural landmarks and international travel. The metro was mentioned as the preferred mode of transport for the majority of these trips, followed by train and bus. A small number of participants also mentioned that they rely on charity-provided lifts to access valued capabilities. One participant expressed the importance of these special transport services:

[Charity A] take us on day trips and we go to a pub for lunch. They have a bus that has a lift so we can get onto it easily. Charity A is my life now, without it I would be very upset and lonely. I would just be sat at home. (Female, Chorlton)

Accessibility as a capability (AaaC)

Figure 2 shows the accessibility of the participants using the AaaC framework. The figure shows how accessibility capabilities and achieved access are derived from the interaction between (public and private) resources and conversion factors. Importantly, the interactions between conversion

factors and resources are revealed. For example, participants display higher metro use due to positive perceptions and use private transport modes due to poor mobility.

Travel experience: values

It was revealed that not all travel was undertaken to reach an activity or place. As such, value was derived from travel itself, or the capability to be mobile. Participants valued the independence, freedom and enjoyment that travel gives them. One respondent remarked:

I like the feeling of independence and freedom when I am travelling. Only my age and mobility are restricting me. (Female Northenden)

The interviews revealed that participants valued simply being able to get 'out and about'. For some, it was important to socialise and avoid loneliness and for others, it was the peripheral, scenic aspects of travelling that they cherished.

I like using public transport, it gets me about to see people. I live alone so it helps with not being alone all the time. (Female, Chorlton)

I watch the seasons changing and listen to music. (Female, Chorlton)

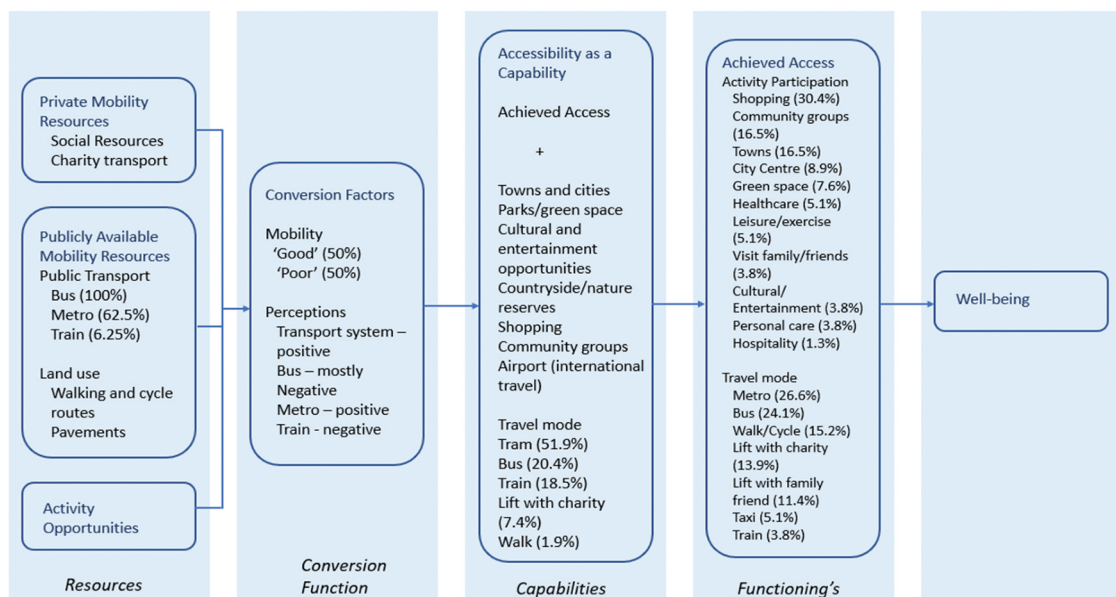

Figure 2. Accessibility as capability of older adults in South Manchester. Note: % is based on the number of people who reported on that item.

I enjoy the residential scenery, there are lovely trees and houses. (Female, Chorlton)

These can be viewed as capabilities, such as the capability to experience freedom or enjoyment. They are subjective and emotive in nature as opposed to functional and relate to the wider transport system, rather than a specific mode.

TRSE dimensions

Table 3 shows the number of references made to each TRSE dimension. Sub-themes were identified for dimensions with a significant number of references. Exclusion based on fear, prejudice and feelings; and physical and cognitive exclusion were the most significant dimensions mentioned with 22 references each, followed by geographical exclusion with 17 references. Time-based exclusion and informational exclusion, although lower, were also mentioned a number of times.

Exclusion based on fear, prejudice or feelings

Participants mentioned a range of concerns based on fear, prejudice and feelings. Some participants described more direct experiences of crime and abuse that led to fear when travelling.

There was a stabbing on the metro a few months ago. I saw the crime scene investigators and a section cornered off. For people to say it's safe, it's clearly not because people are getting stabbed. I saw a woman tooting gas on the tram or some sort of drug and I have seen kids jumping on the tram tracks. I also saw people making fun of a woman saying that she smelt bad. If that happened to me, I would be so embarrassed. (Female, Sharston)

Sometimes coming to or from a hospital appointment people can be mean. I often feel unsafe, people can be mouthy when you are disabled and have been robbed and assaulted. (Female, Northenden)

I am always alert. I never wear anything like necklaces which may look attractive to other people. I never use my mobile phone. Again, I don't want to look vulnerable. (Female, Chorlton)

Several participants mentioned a fear of travelling when it is dark. To many, this a dangerous enterprise they will never embark:

Well, it's not the transport that I fear, it's more walking to and from the bus stop. Just because there is nobody else around. You just feel like 'Gosh there is nobody about'. (Female, Chorlton)

Participants also feared traffic and collisions when travelling, with one participant experiencing actual accident and remarked as:

Table 3. TRSE dimensions with themes.

TRSE Dimension	Number of references
1. Exclusion from facilities	7
2. Geographical exclusion	23
- Transport services don't go to desired location	19
- Distance to transport services is too far from the residence location	4
3. Space exclusion	0
4. Physical and Cognitive exclusion	22
- Inadequate pavements	5
- Saturated vehicle occupancy	5
- Lack of available equipment/infrastructure for disabled people	9
- Difficulties reading information	3
5. Time-based exclusion	13
- Low frequency of transport/service wait time	6
- Journey time	7
6. Exclusion based on fear, prejudice or feelings	22
- Fear of crime and abuse	7
- Feelings of stress and anxiety due to other passengers	6
- Feelings of being unsafe in the dark	5
- Fear of traffic and collisions	4
7. Informational exclusion	8
- Lack of information on service times	6
- Lack of information on routes	2
8. Economic exclusion	3
9. Digital-divide exclusion	3
10. Social-position based exclusion	1

Walking is dangerous. I have been hit from behind several times by bicycles which expect you to jump out of the way which I won't. I can't. (Female, Northenden)

Physical and cognitive exclusion

The study revealed a range of physical and cognitive barriers to accessibility. Firstly, several participants mentioned the inadequacy of pavements and how this makes walking with poor mobility and walking aids very difficult.

I have OA so use walking poles. Chorlton has forest trees growing out of the pavement, these cause the pavement to lift or clip. This is very, very dangerous trip hazard. (Female, Chorlton)

We have pavements, but many are narrow and covered with overgrown hedges, parked vehicles and wheele bins. (Female, Northenden)

Participants also mentioned difficulties finding a seat due to saturated vehicle occupancy.

Vehicle occupancy appeared to dictate whether someone has a pleasant travel experience or not.

Interestingly, it was observed that participants have adapted to the situation by avoiding travelling altogether during busy times such as school rush hour, to avoid difficulties moving and finding a seat.

A range of other issues were mentioned around the lack of available equipment and infrastructure for disabled people. One respondent expressed how the lack of equipment made her ultimately not want to use the bus, which is a clear indication of how TRSE dimensions can result in a lack of capability.

Sometimes there is a bus shelter, but sometimes there are no seats on them, or the seats are dirty and sometimes there is just a pole. 30 minutes is a long time to stand in the rain for someone like me. When you consider all of that, it just makes me not want to use the bus. I would rather stay at home. (Female, Sharston)

Interestingly, it was found that equipment and infrastructure were often present, but they are in most cases in poor condition or not available to use. This included lifts that were out of order, seats that were dirty and uncomfortable, and ramps that were not available to use. It also emerged that bus drivers can be reluctant to lower ramps for seniors and many considered this very worrying. Similarly, information tends to be present but not available to read as participants described having difficulties reading information that is too high, too far away or too small.

Geographical exclusion

There were 17 references for transport services not going to the desired places. Seven of these related to a lack of access to local hospitals and seven related to a lack of access to the countryside. Participants mentioned that travelling to two hospitals in South Manchester (Wythenshawe and Withington Hospital) by public transport was either difficult or impossible. Services appeared to only take them part of the way to the hospital. While some manage to supplement the public transport route with walking, others cannot do it. The role of conversion factors is evident here through differing abilities. One participant summed up these differences:

The sad thing is the lovely tram doesn't go into the hospital either. It's fine if you are relatively able to walk, but if you're not able to walk, it's a problem. I can still walk for an MRI and to the hospital, I can still do it. My husband is struggling. Particularly Wythenshawe. (Female, Chorlton)

It was found that participants who are not able to walk had to rely on lifts from friends and family. This was interesting; it highlights an adaptation strategy to overcome the barrier which can be explained by the necessity of accessing a hospital.

Participants also expressed a desire to access areas of countryside and national parks but pointed out that public transport routes either do not take them there or involve trains which, as discussed, are perceived to be unreliable.

I would like better access to the countryside. The National Trust has three local centres but no easy public transport routes to get there. (Female, Chorlton)

Snowdonia and the peak district are not great for public transport. (Male, Chorlton)

Some participants also mentioned that they were unable to access a bus or tram service due to distance, echoing a mobility challenge, a deterioration in bus services in their local area and a lack of tram stops.

Interestingly, seven out of the 26 participants expressed that they faced no difficulties or barriers travelling and accessing the places they wanted to go. This could indicate that these participants did not face any barriers, which is good for accessibility.

Discussion

The study results reveal that using the CA and TRSE dimensions can provide a more detailed and nuanced

picture of accessibility. Participants had access to public and private mobility resources and used them to access a range of places and activities, which appears positive for accessibility. An exclusive focus on transport provisions (resources) or travel behaviour (functioning) reflects typical approaches in transport studies used to measure accessibility (Miller 2005). It is only with deeper investigation into conversion factors, barriers and values we begin to understand how the transport system may not be serving our older population. The study has demonstrated that the true value of spatial resources will depend on an individual's ability (conversion function) to convert them into valued functioning, which is consistent with previous studies (Vecchio and Martens 2021; Luz and Portugal 2022). The lack of capability to access hospitals in South Manchester is concerning and supports findings by Holley-Moore and Creighton (2015) who reported that older adults throughout England experience this problem. By using the CA, we introduce the role of the conversion function and demonstrate that despite resources being 'available', turning these into a capability is not possible for everyone due to differing levels of individual ability. Transport for Greater Manchester considers both hospitals accessible by public transport (TfGM 2022), yet the findings suggest planners reconsider their decision, considering differing levels of ability. This is important because access to hospitals is a central transport-related human capability (Cao and Hickman 2019a, 2019b), and should be prioritised.

Previous studies remained silent on the role of perceptions in converting resources into functioning. The present findings underscore the importance of perception. Although participants had higher (spatial) access to bus services, the metro facilitated access to more valued functioning and capabilities due to favourable perceptions. This coupled with participants' travel experiences and TRSE provides a better understanding of how perceptions are formed and shaped by experiences of the transport system (Tiznado-Aitken et al. 2020), suggesting that with appropriate interventions, transport perceptions and experiences could be shaped more positively.

The findings also highlight the role of emotions in determining an individual's conversion function, revealing how stress can play a role in achieving access, particularly through perceived danger. The findings support arguments that a myriad of factors, individual abilities, perceptions and emotions

underscore conversion function (Vecchio and Martens 2021).

With the lens of the CA and specifically the conversion factors, we get a deeper understanding of the processes behind converting resources into access, thereby revealing the limitations of the current transport system in Manchester.

Barriers to accessibility

The barriers found in this study are in line with non-capability research, which suggests that physical accessibility, safety, information, and equipment are the key challenges older adults face when travelling (Musselwhite 2017). This reinforces the need for critical interventions. By bringing capabilities and social inclusion into the accessibility sphere, this study suggests that the transport system can disadvantage and restrict people, underscoring the need to do more to address the inequities. Interestingly, the study also reveals that the presence of a barrier does not necessarily determine inaccessibility or exclusion. This is so because older adults have adopted strategies to overcome barriers, such as only travelling at certain times. The ability of older adults to shape their mobility needs has been highlighted in past studies (Nordbakke 2013). The fear of crime, abuse, the dark and traffic collisions create a considerable amount of 'emotional work', which form another set of accessibility barrier. According to Middleton and Spinney (2019), for something to be equally accessible, all users should expend a comparable amount of emotional work and have the same journey quality. This finding highlights the need for transport planners to focus on removing the barriers experienced by different social groups to improve equity and accessibility.

Valued capabilities

In line with the CA, this study attempted to engage with the capabilities older adults' value and have reason to value. The current findings support previous studies (Musselwhite and Haddad 2017; Lin and Cui 2021) which report that older adults tend to value the sense of freedom, independence and enjoyment that travel gives them. This is especially important given that accessibility research tends to exclusively focus on the functional outcomes of travel (Banister 2019). Participants valued the independence; enjoyment travel gives them and the social and scenic aspects of

travel. The importance of such capabilities for well-being are recognised through a central capability lens (Hickman et al., 2017).

Conclusion

This study aimed to analyse the accessibility of older adults of South Manchester employing the Accessibility as a Capability framework (AaaC) and Transport-Related Social Exclusion (TRSE) dimensions. The findings reveal that resource availability does not guarantee accessibility, indicating that more attention needs to be paid to how individuals engage with resources. Older adults were found to possess and value non-functional capabilities, including freedom and enjoyment, important and subjective elements hardly considered in transport research. The study shows that even when activity participation is high, older adults may still expend a significant amount of effort to gain accessibility, specifically fear and stress. The results of this study highlight the importance of subjective factors when 'gaining' accessibility, including perceptions, emotional 'work' and values. In a field heavily concerned with functional and material accessibility needs, the findings call for greater consideration of the individual abilities, perceptions, preferences, values and barriers experienced by those 'gaining' accessibility. Further research may explore the role of particular transport investments in expanding the capability set. Ultimately, accessibility planning should aim to remove barriers and improve access to valued capabilities to create more equitable and sustainable transport systems.

The study has a few limitations. It interpreted capabilities as perceived opportunities, in line with previous studies, yet capabilities are more complex than perceived opportunities. A new approach to measuring this complex concept could be a good exercise for future studies. Another limitation is that the sample was skewed towards females and Chorlton residents due to recruitment support by the Chorlton-based charity that provided transport to the beneficiaries. This means that the results may not be a true representative of those areas without such resources, hence, the findings need to be interpreted with caution. Nonetheless, the findings reveal nuanced features of accessibility associated with the conversion function, presenting policy implications for transport plans in Manchester and other cities that employ capability frameworks. We also recommend future

studies to consider adopting quantitative analysis, drawing on large sample size that is representative enough to understand how the various factors considered in this study interact in shaping transport accessibility among the elderly. Case studies of different contexts would also be important in helping to corroborate the current findings.

Acknowledgments

We would like to thank all the research participants for their time. Special thank you goes to the charity Chorlton Good Neighbours, for allowing the first author to conduct surveys with their beneficiaries.

Disclosure statement

No potential conflict of interest was reported by the author(s).

Appendices

Appendix 1. TRSE dimensions adapted from Luz and Portugal (2022, pp 512–515)

Dimension No.	TRSE Dimension	Description
1)	Exclusion from facilities	Absence of distance to key opportunities such as employment, healthcare, schools, shops or leisure services from where an individual lives. It may also occur when opportunities that can be accessed by public transport are not suitable for the individual.
2)	Geographical Exclusion	Occurs when a person's residence location prevents them from accessing transport services, or the transport system does not connect to the places the person wants to access.
3)	Space exclusion	Occurs when security or space management of some public and private spaces discourage certain groups from using public and quasi-public transport spaces (first class waiting rooms or gated communities).
4)	Physical and Cognitive exclusion	Occurs when transport systems or the built environment may impose physical and cognitive barriers to individuals. This may include design of vehicle, lack of adapted equipment for disabled people, saturated vehicle occupancy, inability to read timetable information, inadequate pavements. Can include a deterioration in eyesight and hearing, poor coordination and slowed reactions. Poor pedestrian infrastructure may increase the risks of falls and stumbles from the elderly and physically disabled.
5)	Time-based exclusion	Time-based exclusion occurs when the low frequency of the transport system, lack of punctuality, or a person demands on time or other commitment may limit travel opportunities and imply the possibility to travel only at times when there is little or no transport services available. Excessive time to access activities may lead to time poverty, where travel is so time consuming that there is little, or no time left for essential activities.
6)	Exclusion based on fear	Refers to the fear of crime and the perception of insecurity or prejudice that makes people avoid certain places. Also, aspects such as quality of the transport mode, safety during the journey and security to access to transport stations, cordiality of service providers influence the feeling about public transport and the perception of it as an option for travelling. Feelings about built environment elements such as neighbourhood aesthetic and public lighting may influence the ease of access to activities.
7)	Informational Exclusion	Refers to the lack of available information on public transport and destination options that prevent individuals from planning their journey and, therefore, limit its use.
8)	Economic Exclusion	Economic exclusion occurs when the monetary costs of travel prevent people from travelling or restrict their access to destinations around their homes or mandatory activities.
9)	Digital Divide	Digital divide exclusion occurs when the lack of digital connection or inability to use appropriate ICT may prevent individuals from using app-based transport systems.
10)	Social Position-based exclusion	Social position-based exclusion refers to the prevention from moving in public spaces due to censure, social control or any other restriction based on one's social position (e.g. age, gender, race, ethnicity, caste, religion).

Appendix 2. GMAL Scores

Accessibility Level	Range of Index Scores	Description	Map Colour
1	0 , <=0.5	Very Low	
2	>0.5 , <=2.5		
3	>2.5 , <=5.0		
4	>5.0 , <=7.5		
5	>7.5 , <=12.5		
6	>12.5 , <=17.5		
7	>17.5 , <=25.0		
8	>25	Very High
