## 34 Abstract

35 Brain health is a pressing global concern. Poor diet quality is a recognized major  
36 environmental risk factor for brain disorders and one of the few that is modifiable. There is  
37 substantial evidence that nutrition impacts on brain development and brain health across the  
38 life course. So why then is the full potential of nutrition not utilized to improve brain function?  
39 This commentary, which is based on discussions of the European Brain Research Area  
40 BRAINFOOD cluster<sup>1</sup>, aims to highlight the most urgent research priorities concerning the  
41 evidence base in the area of nutrition and brain health and identifies three major issues that  
42 need to be addressed: 1) Increase causal and mechanistic evidence on the link between  
43 nutrition and brain health; 2) Produce effective messages/education concerning the role of  
44 food for brain health, and 3) Funding to support collaborative working across diverse  
45 stakeholders.

### 46 47 **Costs associated with brain health conditions.**

48 Non-communicable diseases associated with brain health, including neurological and mental  
49 health conditions such as dementia, depression, and obesity, are highly prevalent<sup>1-3</sup> and  
50 translate into an immense burden on society. For example, neurological and psychiatric  
51 disorders each account for more than 16 million disability-adjusted life years (DALYs), the loss  
52 of the equivalent of one year of full health on average.<sup>3</sup> The most debilitating conditions are  
53 stroke, Alzheimer's disease and other forms of dementia.<sup>4</sup> Stroke accounts for more than 1  
54 million deaths per year and Alzheimer's disease (and other forms of dementia), and  
55 Parkinson's disease are among the top 3 causes of death due to neurological disorders in  
56 Europe.<sup>3</sup> Additionally, neurodevelopmental conditions such as Attention-deficit Hyperactivity  
57 Disorder (ADHD) and Autism Spectrum Disorder and mental health conditions such as  
58 substance use disorders, depressive disorders, anxiety disorders and schizophrenia are the  
59 leading causes of disability.<sup>3</sup> Population ageing and growth is predicted to drive large  
60 increases in the number of individuals affected by dementia globally.<sup>4</sup> Treating brain health  
61 conditions is also costly. For example, brain health conditions account for 35% of Europe's  
62 total disease burden with a yearly cost of almost €800 billion, which likely is an  
63 underestimation.<sup>5</sup>

64  
65 Overweight and obesity both provide a risk for metabolic health but also for brain health and  
66 are increasing at a rapid rate globally.<sup>6</sup> Moreover, overweight and obesity are increasingly  
67 prevalent in children. Of particular concern is the rapidly growing number of women becoming  
68 pregnant whilst having overweight or obesity which can have serious long-term consequences  
69 for their children's metabolic and brain health.<sup>7</sup> At the same time, the widespread increase in  
70 food insecurity<sup>8</sup> poses significant challenges for brain health due to its negative impact on  
71 nutritional status and mental health.<sup>9</sup> The triple burden of malnutrition (i.e., overnutrition and  
72 obesity, undernutrition, and micronutrient deficiencies) reaches beyond health, since  
73 individuals fail to reach their full potential in terms of wider economic and societal  
74 contribution.<sup>10</sup> These challenges extend beyond the responsibility of the individual and can  
75 only be tackled by a serious overarching and sustained approach by governments, the food  
76 industry, and society working together.<sup>11</sup>

## 77 The potential of nutrition for brain health

78 Nutrition affects all aspects of brain development and brain function, which means that there  
79 is the potential to modify the diet and/or use nutritional interventions to prevent and treat brain  
80 health conditions. The field of nutritional psychiatry has taken off recently<sup>12</sup> and accumulating  
81 results of observational and intervention studies support a role for diet in depression onset  
82 and symptom management.<sup>13</sup> In addition, trials on clinical depression and in non-clinical  
83 populations suggest that addressing diet quality is an efficacious and cost-effective way to  
84 reduce symptoms.<sup>14-17</sup> Nutritional interventions have the potential to reduce cognitive decline  
85 and change the course of neurodegenerative diseases. For example, while there is no overall  
86 cure for dementia, there is a clear link between diet and the risk of dementia and dietary  
87 interventions have been shown to delay the onset or progression of the disease. Moreover,  
88 early intervention is more beneficial than late intervention.<sup>18-21</sup> However, a recent review of  
89 studies investigating the effect of consumption of food groups that are recommended as part  
90 of a healthy sustainable diet (e.g. wholegrain, fruits and vegetables) found that high-quality,  
91 strong *causal* evidence of the effects of these food groups on cognitive function across the life  
92 course is lacking.<sup>22</sup>

93  
94 Nutritional interventions may hold great promise for intervention early in life.<sup>23</sup> The potential  
95 for nutrition to affect brain health across the life course when intervening in early life is high  
96 because important developmental processes are occurring, including neurogenesis and  
97 myelination that set the ability to develop cognitive and behavioural functions and individual  
98 resilience to later life challenges.<sup>24</sup> During pregnancy and lactation, nutritional interventions  
99 can affect both the mother and her offspring: as an example, as well as its well-documented  
100 effect on the prevention of neural tube disorders, supplementation with folic acid and  
101 multivitamin products before and during pregnancy lowers the risk of the offspring  
102 developing autism.<sup>25,26</sup> Moreover, both micronutrients and omega-3 fatty acid  
103 supplementation have been directly linked to a reduced likelihood of preterm birth, a known  
104 risk factor for neurodevelopmental problems with lifelong consequences.<sup>27,28</sup> However, more  
105 needs to be done, as supplementation programs, in Europe, have not reached their full  
106 potential.<sup>28</sup> For example, folic acid taken before pregnancy and in early pregnancy reduces  
107 the risk of a neural tube disorders. Yet, despite Public Health Initiatives across Europe  
108 recommending that women take 0.4 mg folic acid before becoming pregnant and during the  
109 first trimester, the prevalence of neural tube disorder pregnancies has not materially  
110 decreased in the EU since 1998. This result is in stark contrast to a dramatic fall observed in  
111 the USA, where fortification of flour with folic acid has become mandatory, concurrent with  
112 supplementation advice.<sup>29</sup> Also, there is generic advice, but no public health initiatives in  
113 Europe to highlight the relevance of adequate intake of omega-3 fatty acids via the diet and  
114 supplementation to reduce the risk of preterm birth, something that is currently being  
115 implemented in health care systems across Australia.<sup>30</sup> There is compelling evidence  
116 showing that the elimination of food additives, colorings and preservatives reduces  
117 symptoms of ADHD and that supplementation with omega-3 fatty acids and vitamins may  
118 decrease symptoms of ADHD and autism.<sup>31,32</sup> The efficacy of early dietary interventions is  
119 supported by pre-clinical studies. There is evidence that early dietary supplementation with  
120 essential micronutrients and omega-3 fatty acids can protect against the negative  
121 consequences of exposure to early-life adversity on brain structure and function.<sup>33,34</sup> This is  
122 key because early-life adversity is one of the main risk factors for developing  
123 psychopathology and metabolic disorders later in life.<sup>35</sup>

124 More broadly, early-life environment and experience have a major impact on the risk of  
125 developing brain and metabolic disorders later in life suggesting that such risks have an early-  
126 life origin. For example, there is an increasing prevalence of mothers suffering from mental  
127 health problems (e.g. depression, addiction, trauma) as well as overweight and obese  
128 pregnancies that are associated with a higher risk of pregnancy complications (including  
129 preterm birth) and importantly, lasting consequences for the later life health risks of the  
130 offspring.<sup>36</sup> These are a serious concern, as often such early environments cannot be avoided  
131 and thus require a holistic approach to break the intergenerational cycle. These examples  
132 emphasize the relevance of considering the interaction between nutrition and brain health from  
133 a longer-term perspective. Many brain health problems are associated with diet and lifestyle  
134 risk factors that have occurred or started much earlier in life.

135  
136 Across all age groups, maintaining balanced energy intake is essential to avoid both harmful  
137 energy deficits from malnutrition and the negative impacts of obesity resulting from  
138 overnutrition. However, each age group has distinct nutritional needs that are vital in regulating  
139 cognitive function and it is recommended to employ different interventions at different life  
140 stages, as each stage is characterized by specific physiological changes and related health  
141 targets. For instance, in midlife supplementation via nutraceutical compounds might be useful  
142 to prevent low-grade inflammation and in older adulthood, combining a healthier lifestyle with  
143 energy restriction presents a practical approach to slowing cognitive decline.<sup>37</sup>

144  
145 Nutritional interventions have the potential to be employed throughout life, and in some cases,  
146 they appear perhaps even preferable to classic medication in treating emerging conditions,  
147 with greater consumer acceptance and lower side effects. However, there are still some major  
148 gaps in our understanding of the potential for specific nutritional strategies at each life stage  
149 <sup>33</sup> and many questions that are yet to be answered, including which interventions work, for  
150 whom and how best to translate the results of observational studies and experimental models  
151 into effective trials that provide more high-quality causal evidence for a role of nutrition in  
152 improving brain health.

## 153 How best to demonstrate the impact of nutrition on brain health?

154 There are many methodological challenges associated with the design and implementation of  
155 studies to test the effects of nutritional interventions on brain health, including issues with  
156 ensuring intervention adherence and blinding as well as the specific composition, and mode  
157 of diet delivery, that have been discussed in detail elsewhere. <sup>12</sup> Here we outline some specific  
158 issues for consideration as the evidence base builds.

## 159 Importance of understanding mechanisms.

160 The mechanisms of action associating diet with mental health outcomes are complex,  
161 interrelated and impinge on multiple biological pathways. Diet can have an important effect on  
162 several processes and mechanisms involving inflammatory markers, oxidative stress,  
163 mitochondrial function, and neuroendocrine effectors.<sup>38</sup> Evaluating which dietary components  
164 are beneficial for an individual requires greater mechanistic insight into individual genetic and  
165 environmental contexts to exploit the potential for food e.g. to reduce inflammation and  
166 oxidative stress while improving neuroendocrine function in response to everyday challenges.

167 Furthermore, epigenetic mechanisms are potentially involved in the long-term effects of dietary  
168 intake as well as in the intergenerational transmission of basic mechanisms and behaviors  
169 underlying food choices and susceptibility to mental disorders.<sup>39</sup> In addition, there is a growing  
170 appreciation of the role of the microbiome and microbial metabolites in shaping brain and  
171 behavior and the pathways of gut-brain signalling are being resolved.<sup>40-42</sup> Conversely, diet is  
172 one of the key factors that shape the microbiome composition across the lifespan.<sup>43</sup> The  
173 breadth of action of each specific nutrient and the complexity of interactions of various  
174 nutrients with the microbiome make disentangling the direct and indirect effects of nutrition on  
175 brain function and the specific neurobiological mechanisms involved challenging.<sup>37,44</sup> A novel  
176 framework to develop and evaluate the evidence base of how nutrients impact the brain is  
177 thus required.

## 178 Importance of stratification.

179 Studies to investigate possible beneficial effects of specific nutrients need to address  
180 perceived or anticipated nutrient gaps due to health issues, the diet or the environment as well  
181 as investigate the effects of specific nutrient levels above the recommended intake. This  
182 ideally should be studied in the context of the background diet that may be adequate or not in  
183 providing these nutrients. For example, in a gestational diabetes mellitus study, differences in  
184 the effect sizes of interventions were related to the background diet, which varied considerably  
185 in carbohydrate intake levels.<sup>45,46</sup> Many of the nutrients that may benefit brain health may  
186 already be an integral part of our diet, yet, depending on the habitual diet, intake levels may  
187 vary considerably. It has recently been shown that individuals with a balanced diet pattern, as  
188 estimated from a large data set of food preferences across a range of food categories, show  
189 better mental health and superior cognitive functions relative to other dietary patterns e.g. high  
190 protein and low fibre dietary pattern.<sup>47</sup> Nutrient requirements vary due to individual health, life  
191 stage, and lifestyle. Thus, individual nutrient needs are driven by physical and psychological  
192 health, habitual diet and lifestyle, and differ across the life course and according to the  
193 environment and challenges encountered.<sup>48-50</sup> In addition, nutrients serve as building blocks  
194 as well as acting as signaling molecules, providing the energy to perform daily tasks whilst  
195 maintaining body homeostasis. Recommendations for adequate intake of nutrients  
196 (recommended dietary allowance) are designed to cover the needs of 97% of the population,  
197 but given the normal distribution of individual requirements consequently overestimate the  
198 required intakes for most individuals to prevent deficiency at a population level. NHANES data  
199 suggests that actual sufficiency is closer to 70% of the population, highlighting the need to  
200 focus on deficiencies pertinent to specific target groups rather than at population level.<sup>51</sup>  
201 Specific subgroups (e.g., individuals with specific genetic vulnerabilities) may show a different  
202 response to a particular intervention compared to others and effects on a specific brain health  
203 domain may only be visible in a vulnerable population. This vulnerability could be determined  
204 by nutritional status (e.g., deficiency or insufficiency) or health status e.g., supplementation is  
205 most effective in treating deficiency in disease states. Ultimately, some recommendations may  
206 need to be stratified and personalized, while other recommendations may be beneficial for  
207 larger groups of people. However, personalisation is not without challenges including the  
208 implementation of (widespread) screening that may have ethical limitations and prove costly  
209 to implement.

## 211 Foods are not drugs.

212 Research into the efficacy of specific nutrients on brain health outcomes is more complex than  
213 studying drug efficacy.<sup>52,53</sup> The expectation that the research meets the standards set by  
214 regulatory bodies required for claims on the benefits of foods and nutrients does not  
215 acknowledge that the business models and the possible return on investment are entirely  
216 different from those of the pharmaceutical industry. With rare exceptions for specific nutrients  
217 and bioactives, food products cannot be commercially protected in the same way that new  
218 pharmaceutical molecules, designed to a specific receptor or mechanism of action, although  
219 safety assessment may require similar investments as for pharmaceutical compounds.  
220 Moreover, food manufacturers need to incorporate the nutrients of interest in an attractive and  
221 tasty product that can be marketed directly to the consumer and needs to be bought and  
222 consumed voluntarily regularly to achieve the beneficial effect. The required investment in  
223 research that is needed to test and show the efficacy of a specific product is substantial and  
224 unlikely to be matched by the potential financial return on investment. For example, improving  
225 intake of dietary fibre could have beneficial effects on many aspects of brain health, but the  
226 costs of running large-scale clinical trials that are not likely to lead to any proprietary  
227 knowledge may be prohibitive. The food industry has a role to play in building the evidence  
228 base but cannot act alone. An important consideration here is that for the food industry/private  
229 sector there is limited return on investment for research in this area, except for specific  
230 nutrients and bioactives or combinations thereof, where an application for a health claim is  
231 possible. Generation of the scientific evidence requires public funding. Harvesting the  
232 enormous health and cost-saving potential of nutritional interventions to maintain brain health  
233 and reduce the risk of brain diseases is a public health issue that is impossible to address  
234 without relevant public funding support, although the food industry has a moral obligation to  
235 work towards developing and providing healthy foods to the market. These challenges and  
236 complexities mean that nutrition in the context of brain health is an under-investigated scientific  
237 area, but also that it is under-researched as it has not (yet) been prioritized by funding bodies.

## 238 Importance of effective messaging.

239 Following dietary recommendations for health can be difficult but adherence may be improved  
240 if, in addition to knowing about distal benefits to physical health, people are aware that dietary  
241 change can have more immediate effects on mental and brain health. Nearly 9 in 10 adults  
242 said they would eat a healthier diet if they knew it would lower the risks of cognitive decline  
243 (87%), heart disease (88%), and diabetes (88%).<sup>54</sup> More than 60% of adults aged 40 and older  
244 said that they would eat more fish, less red meat, and lower their dairy fat intake if they knew  
245 it was good for their brain health.<sup>52</sup> A focus on the brain health benefits that accompany an  
246 improvement in diet quality rather than focusing on the benefits of weight loss may also be  
247 helpful for encouraging behavior change because a focus on weight can be stigmatizing.

248  
249 Yet an issue is that consumers and patients are often faced with a barrage of conflicting and  
250 inconsistent findings about the potential (proximal) health effects of foods. This results in a  
251 lack of trust. In 2018, 80% of consumers reported coming across conflicting information about  
252 food and nutrition, which made them doubt their choices.<sup>55</sup> Social influencers are now a  
253 popular source of nutritional information, yet the advice provided is rarely founded on solid  
254 scientific evidence: at best it may be incomplete and incorrect, and at worst, harmful. The  
255 public may also receive differing advice from health-care providers on nutrition and health.

256 This may be in part because nutritional education in the medical curriculum is sparse, and the  
257 role of dietitians in the prevention and management of brain disorders is also limited.<sup>56,57</sup>

## 258 BRAINFOOD Priorities.

259 Recently there have been a number of initiatives in the US, Europe and Australia that testify  
260 the fact that diet and nutrition are important priorities for public health. Just as an example, in  
261 the US the “Food is medicine” Institute has been developed at Tufts University. The aim is to  
262 develop a set of food-based nutrition programs and interventions integrated into the healthcare  
263 system to advance specific health needs and health equity in different populations. Also, they  
264 are aiming to overcome one of the major drawbacks so far, which is the lack of large  
265 randomized clinical trials in different patient populations as well as estimating costs, cost-  
266 effectiveness, and effects on disparities of specific programs in addition to assessing public  
267 perceptions of the public for the subject. In Australia, the Food & Mood Centre has been  
268 founded by researchers also animating a specific Scientific Society: The International Society  
269 for Nutritional Psychiatry Research (ISNPR). In Europe, the initiative “Healthy Diet, Healthy  
270 Life (HDHL)” has been set up bringing together 17 countries that align research programming  
271 and fund new research to prevent or minimize diet-related chronic diseases  
272 (<https://www.healthydietforhealthylife.eu/>). Although not being directly linked to brain health,  
273 these programs have the merit to put diet and nutrition under the spotlight as major  
274 determinants of health. Within the European College of Neuropsychopharmacology (ECNP) a  
275 specific section on nutrition and mental health (Nutrition network) is present made up by many  
276 of the authors of this article. Overall, there is a surge of initiatives, both linked to scientific  
277 societies or Institutions or funding bodies and legislators that are attempting to align research  
278 education and policy in nutrition for brain health.

279  
280 Given the potential of nutrition to support brain health, further investment in research to build  
281 a robust evidence base, in addition to education of health care professionals on this topic is  
282 urgently required. The link between a healthy, balanced diet and brain health calls for  
283 substantial action from policymakers to enable knowledge-building on diets that support brain  
284 health to make these accessible for all. The lack of consensus on the effects of diets and  
285 nutrients for brain health is in part related to the limited evidence base, since the number of  
286 high-quality studies that have been published to date is relatively small. With a few exceptions,  
287 most nutrient-brain health associations are driven by diet and lifestyle, meaning that the  
288 question of whether the effects of nutrition on the brain are independent or correlate of other  
289 healthy behaviours remains open. There is also a strong need for holistic, appropriate  
290 nutritional recommendations tailored to individual needs and age. Both the quality and  
291 strength of evidence need to be improved and disseminated in a clear, consistent, and  
292 accessible manner.

293  
294 **The most urgent research priorities in the BRAINFOOD area are:**

- 295  
296 **1. Identify nutrients and nutritional interventions that impact on brain health.**  
297 The transfer of findings from basic biomedical research into medical application is one  
298 of the major challenges in nutrition research. For specific nutrients or nutritional  
299 interventions where there is already a substantial evidence base, further trials are  
300 required to confirm the impact on brain health. The use of more stringent statistical

301 approaches in analyzing data from observational studies, such as Mendelian  
302 Randomization to control for hidden confounders would allow for (cautious)  
303 conclusions about causality to be drawn. Cohort research on clinical nutrition should  
304 systematically collect clinical data in databases and registries that are standardized  
305 and accessible at the individual level. Relevant and measurable patient-centered  
306 outcomes and appropriate study designs are needed, and international cooperation  
307 and multi-stakeholder engagement are key for success. The power of omics strategies  
308 (genetics, metabolomics, microbiomics, nutriomics) needs to be utilized to understand  
309 how individual differences in nutritional status and intake impact brain health.  
310 Systematic and interoperable data curation way would allow integration and scaling up  
311 of current levels of analysis, but this needs to be grounded in advances in technologies  
312 for a more robust and reliable assessment of diet to ensure data quality and reliability.  
313 The development of a Nutrition Research Infrastructure or Knowledge Platform  
314 enforcing FAIR principles, harmonization and standardization of study designs and  
315 data curation would strengthen networking between researchers and deliver relevant  
316 information to stakeholders, policymakers and the public in accessible and usable  
317 form.

318 **2. Identify and explore the neuronal circuits, cells and molecules linking nutrition**  
319 **with brain health.**

320 We need to unravel which effects of nutrition are direct or indirect and additionally  
321 determine the relative contribution of hormonal, immune and microbiome systems. In  
322 addition, the contributions of single nutrients and how they act in combination need to  
323 be elucidated. For which nutrients or combinations are there sufficient molecular and  
324 cellular insights to explain the mechanism of action on brain health? We need to  
325 identify truly innovative approaches to better understand the relationship between  
326 nutrients and brain health and to integrate this with research on food palatability and  
327 taste in order to direct human food choice towards beneficial nutritional intake. A  
328 mechanistic understanding of how food impacts brain health will not only assist in  
329 identifying those at risk but also more convincingly explain why a healthy and balanced  
330 diet providing nutrients in adequate amounts is important for brain health.

331  
332 **3. Bridge basic science mechanisms to clinical outcomes by identifying**  
333 **biomarkers.**

334 While a large literature based on preclinical animal studies already exists, intervention  
335 studies investigating markers related to clinical outcomes are needed. Experimental  
336 Medicine studies in humans involve assessing the effects of controlled exposure to an  
337 intervention and identifying early-stage markers that predict clinical outcomes. Markers  
338 can include biological measures e.g., neurotransmitter levels, or neurocognitive  
339 measures e.g. brain imaging measures. Such studies should be employed to optimize  
340 the selection of nutrients that can then be tested in lengthy and more expensive  
341 randomized controlled trials.

342  
343 **Conclusion**

344  
345 Addressing the challenges and priorities in the brain food field will result in tremendous  
346 benefits for society but cannot be achieved without the support of policymakers. We, the  
347 BRAINFOOD cluster, therefore, ask the policymakers to act and call for more research  
348 funding. We have identified three major issues that need to be addressed:

349

350 **1. Increase causal and mechanistic evidence on the link between nutrition and brain**  
351 **health.** Intuitively, people know that food is important for health but the current scientific  
352 evidence causally linking a selected type of diet and/or specific nutraceuticals with  
353 protective/beneficial effects on brain health is not yet based on extensive randomised clinical  
354 trials.

355

356 **2. Produce effective messages/education concerning the role of food for brain health.**  
357 There is poor understanding of how nutrition supports and maintains brain health both by the  
358 general population and by health professionals. The lack of evidence-based advice is further  
359 complicated by confusing and exaggerated messaging in the popular press. Nutritional  
360 education should be much higher on the agenda of healthcare professionals and  
361 governmental bodies.

362

363 **3. Funding to support collaborative cross-sector working.** Healthy nutrition for the brain  
364 requires access to safe, nutritious, affordable and culturally appropriate diets, throughout life,  
365 for all citizens. This cannot be achieved without public, private, and community sectors working  
366 together to improve the food environment and strengthen the link between food and health for  
367 consumers.

368

369 <sup>1</sup> Footnote

370 BRAINFOOD Cluster Description: The European Brain Research Area project — EBRA, led  
371 by the European Brain Council - EBC - and together with 3 other EU initiatives (ERANET-  
372 NEURON, JPND, and Human Brain Project) was created as a catalysing initiative for brain  
373 research stakeholders to streamline and better coordinate brain research across Europe.  
374 BRAINFOOD is an EBRA cluster that aims to positively impact brain health by improving the  
375 nutrition of European citizens based on fundamental insights into the bidirectional links  
376 between brain health and nutrition. The Cluster has been built in the framework of the Nutrition  
377 Network of the European College of Neuropsychopharmacology (ECNP).

378

### 379 **Funding**

380 The BRAINFOOD cluster is supported by the European Brain Research Area project. EBRA  
381 has received funding from the European Union's Horizon 2020 research and innovation  
382 programme under grant agreement number 825348 JB has been supported by the  
383 Horizon2020 supported programmes CANDY Grant No. 847818 and PRIME Grant No.  
384 847879. SLD is supported by the Swedish Research Council (2022-00713), NovoNordisk  
385 Fonden (NNF0078215), Hjärfonden (FO2023-0437) and Swedish Government and the  
386 county councils in the ALF agreement (ALFGBG-965364). RA is supported by ERANET-  
387 NEURON 2018, grant number MIGBAN FKZ: 01EW1906A, the Swedish Research Council for  
388 Medicine and Health (2018–02588), Vrienden van het UMC and the Netherlands Organisation  
389 for Scientific Research (ALWOP.137, OCENW.M.22.111, Gravitation grant 024.004.012). AK  
390 is funded by Alzheimer Nederland, ZonMW and JPND.

391

### 392 **Conflict of Interest**

393

394 JB has been a consultant to / member of advisory board of / and/or speaker for Takeda, Roche,  
395 Medice, Angelini, Janssen, and Servier. EvdB is an employee of Nestlé Research, Produit de  
396 Nestlé SA, Lausanne, Switzerland. JC has received research funding from 4D Pharma,

397 Cremo, Dupont, Mead Johnson, Nutricia, and Pharmavite; has been an invited speaker at  
398 meetings organized by Alimentary Health, Alkermes, Ordesa, and Yakult; and has served as  
399 a consultant for Alkermes and Nestle. LD has Current funding from: UKRI and WBANA;  
400 Consultancy with Hass Avocado Board, Mars; Positions: ILSI Europe Board member; ILSI  
401 Global Board member. All other authors have no conflict of interest to declare.

402

### 403 **Author Contribution**

404 All authors contributed to the conceptualization and writing of the manuscript.

405
