2 **After Sandy – rethinking flood risk management**
3 **in Asian coastal megacities**

4 Faith Ka Shun Chan¹, Nigel Wright², Xiaotao Cheng³, James Griffiths⁴

5
6 The tropical storm, and for a time hurricane, named Sandy arrived on the US East Coast on 30th
7 October 2012, and delivered a 5.1 meters storm surge, the highest since 1851, to the heart of the
8 country's financial hub in the Lower Manhattan area in New York City (Figure 1) (NOAA
9 2012). As a result, there were more than 40 fatalities across the city, and the storm-related death-
10 toll across the North East US reached 63. 69 deaths in the Caribbean region meant that total
11 casualties caused by the storm was 132 (BBC 2012; Fischetti 2012). Public transport systems
12 were submerged; the runways of two major airports (John F Kennedy and Newark) were flooded
13 and closed; and the New York Stock Exchange was shut-down for two days. The forecasting

14 firm Equcat estimated the likely total cost of damages to be over \$85 billion (Reuters 2012a).
15 Reuters estimated damage of at least \$18 billion in the area between downtown and Long Island
16 alone (Reuters 2012b). To put this in context, average annual losses from cyclones, storm surges,
17 coastal floods and winds in the US are estimated to be in the region of just \$10 billion per year.

18 Although the magnitude of Sandy was less intense than Katrina in 2005, Sandy affected a larger
19 area; NASA (2012) reported the strong winds (greater than 65 km/h) for a distance of
20 approximately 500 km during Hurricane Katrina, whereas Sandy prevailed for over 1,500 km at
21 a similar intensity. This is possibly the main reason why Sandy generated sea surges over a
22 larger coastal area than Katrina, and affected more than 12 states on the East coast (CCTV 2012).

23 Previous research (Webster et al. 2005), has indicated that the frequency and intensity of
24 cyclones (i.e. hurricanes and typhoons) has increased in the last 50 years, and that the trend is
25 expected to rise continuously this century due to climate change. The IPCC (2012) also reported
26 that it is likely that there has been a pole-ward shift in the main Northern Hemisphere extra-
27 tropical storm tracks, which means that the potential for intense storms that produce significant
28 wind and extreme rainfall is slightly increased.

29 The impact of Storm Sandy reflects the vulnerability of coastal megacities across the globe. This
30 vulnerability exists because human settlement, including properties and infrastructure, is mostly
31 located in low-lying flood-prone areas similar to those of New York City. The major financial
32 hub of Wall Street for example, is just a mile away from the harbor. An accepted definition of a
33 megacity is a city with a population of 8 million or more (United Nations 2010). New York City
34 has 8.2 million inhabitants, approximately 2 million of whom live on Long Island or smaller
35 islands and in flood-prone areas. The city government realised that it would be impossible to

36 relocate this number of people and associated assets outside of the hazard areas, and have
37 therefore started to adapt the flood management strategies in preparation for climate change
38 (NYC 2012). Adaptation practices such as assessment of surge-risk, flood-risk mapping,
39 prediction of risks from various climate scenarios, and enhanced emergency evacuation plans
40 have been implemented since 2010 (Klima et al. 2011).

41 The city's storm warning system was activated some 41 hours before Storm Sandy arrived, at
42 which point the city authorities announced the closure of the financial markets and advised
43 residents to stock-up on food and water. Recommendations to employ sand-bags for flood-
44 proofing and property protection, and advice to residents to stay at home or move to safe areas in
45 preparation for the storm, were examples of good practice (BBC 2012). Without such measures,
46 it is highly likely that the casualty count and damage caused by the storm would have been much
47 worse.

48
49 **Figure 1.** Up to 5.1-m tidal surge overtopped embankments along the coastline (Lucas Jackson,
50 photographer; with permission from Thomson Reuters)

51
52 Looking across the coastal regions of Asia, most coastal megacities have developed within the
53 last three decades. During the 1960s Tokyo was the only coastal megacity in Asia, whereas now
54 there are seven (Osaka-Kobe, Shanghai, Jakarta, Manila, Seoul, Guangzhou, Shenzhen and Hong
55 Kong). The fact that these coastal cities are ports means that their economic policies are oriented
56 towards trading and exporting products. Asian countries like China and Vietnam have
57 established Special Economic Zones (SEZ) in coastal cities (e.g. Shenzhen) which give special
58 tax incentives for foreign investors to encourage international trade and investment. This leads to
59 higher rates of employment and business opportunities. For example, the former fishing town of
60 Shenzhen has grown from just 300,000 people in 1979 to over 8 million at the present time
61 (including guest and itinerant workers). A number of other Pearl River Delta cities have recorded
62 similar growth rates within the last three decades (Yeung 2011). Emerging coastal cities in South
63 East Asia also appear to be following the success story of the Chinese SEZs. Yangon in
64 Myanmar for example recorded a population growth of 22% over the last decade as the
65 government opened its doors to economic reform (Seto 2011).

66 All coastal megacities in South East Asia are exposed to storms (cyclones/typhoons) similar to
67 Storm Sandy and many have suffered from a number of severe sea surges and inundations in
68 recent years. Typhoon Nargis in 2008 for example, inundated land up to 75 km inland in the
69 Rangoon and Irrawaddy Delta areas on the south coast of Myanmar; which resulted in the death
70 of over 146,000 people, and total economic damage of over \$17 billion (Syvitski et al. 2009).
71 Similarly, storm surges driven by Typhoons Hagupit and Koppu in 2008 and 2009 respectively,
72 inundated the low-lying coastal areas of Tai O town in Hong Kong, damaging over 100
73 properties. Most of the city infrastructure (e.g. business and residential properties) are

74 unfortunately located on flood-prone areas. Shenzhen is another example of a high-risk area, as
75 many properties have been built in flood-prone areas (such as the Harbour-front area). Even as
76 the city becomes increasingly urbanised (up to over 98%), the demand for land is still increasing
77 (Luo and Shen 2012). As the availability of land decreases, the municipal government has started
78 to develop the Futian coastal wetland area, which previously functioned as a flood-storage area.

79 More than 86% of the Pearl River Delta's coastal areas currently rely on hard flood-protection
80 measures such as dykes and embankments, but only a limited proportion of these are designed to
81 withstand a 1-in-100 year event of a similar scale to Storm Sandy (Chan et al. 2012). In fact,
82 existing flood management practices in many coastal megacities in Asia are devoid of planning,
83 projections and adaptation strategies that account for future climate-change, and are thus
84 unprepared for extreme storms such as Storm Sandy. Given these circumstances and the
85 likelihood of future climate change, a number of researchers have cautioned that Asian coastal
86 megacities, both existing (e.g. Shanghai, Guangzhou, Hong Kong, Bangkok, Yangon, Tokyo,
87 etc.) and emerging (e.g. Ningbo, Tianjin, etc.), will be particularly vulnerable as they are facing
88 common constraints caused by rapid growth (i.e. populations and economic), urbanisation and
89 land scarcity (AFP 2012; Balica et al. 2012; Hanson et al. 2011).

90 This situation suggests that, although unpalatable to land planners and decision makers, measures
91 such as prevention of further development on floodplains, remain the most effective way to
92 avoid flood damage. Such measures should be combined with hydrological modelling and flood-
93 risk mapping and forecasting to assist planners in making well-informed decisions. Before
94 achieving these objectives, there are two issues that should perhaps first be considered. Firstly, it
95 is difficult to rely purely on statistical assumptions and the use of climatic modelling to
96 extrapolate future extreme events (i.e. precipitation and storm patterns), that have not yet been

97 observed (Schnoor 2008). Accordingly, it will be difficult to accurately predict future
98 hydrological changes and cyclonic effects in coastal cities associated with future climate change.
99 Secondly, not all coastal megacities have undertaken good flood-risk management practice, such
100 as the design of early warning systems, and emergency excavation and flood relief plans (as had
101 been done in New York). Indeed, most cities in Asia are still reliant on wholly engineering-based
102 flood defence, without the benefits of holistic flood management, such as preparedness,
103 awareness and emergency evacuation plans to cover all parts of the city. The most recent coastal
104 floods in Hong Kong for example, reflected a flood warning system that is only operational for
105 certain parts of the city. There was no comprehensive flood emergency evacuation plan, and the
106 institutional responsibilities related to coastal flooding were blurred (Chan et al. 2012).

107 The reality for many SE Asian coastal cities then, is that far too many developments have been
108 placed in floodplains and many new plans continue to focus on developing these areas. This
109 pattern seems unavoidable on the Asian coastline which is subject to huge population and
110 economic growth. However, we need to constantly remind people that these low-lying
111 floodplains are naturally exposed to floods and cyclonic effects (Syvitski and Kettner 2011). In
112 addition, it is expected that climate-induced sea-level rise will increasingly affect these
113 megacities.

114 Relocation is impossible in the megacities due to their huge settled populations, and is surely the
115 last option in terms of socio-economic control. Whilst strategic abandonment in areas of
116 particularly high risk would at least ensure people's safety (Neville and Coats 2009),
117 abandonment would also lead to difficulty in relocating large numbers of residents to other areas.
118 Municipal governments therefore, have to raise their resilience and safety level as the first
119 priority. This can be done through practices such as utilising flood-proofing techniques;

120 enforcing emergency evacuation and design of flood relief plans (e.g. ensuring emergency food
121 and freshwater storage, interconnecting with various emergency service departments – medical
122 and police, temporary shelters and financial supports) (Cheng 2006); improving flood warning
123 systems to ensure people can respond and react in time (Ma et al. 2010); educating the public to
124 prepare for storms and floods; and starting to reform the spatial landuse and planning system to
125 address flood risk (Porter and Demeritt 2012).

126 In conclusion, lessons from Storm Sandy and Katrina imply that it is just not possible to
127 comprehensively protect coastal megacities from extreme storms and the resulting floods.
128 Increasingly unpredictable climatic impacts mean that embankments and flood gates are will
129 always have the potential to be breached during such extreme weather conditions. To ensure our
130 safety and the safety of the infrastructure that we rely upon requires us to continually learn and
131 re-evaluate our approach to flood management. Living with storms and being vigilant in our
132 preparations will make us more resilient and adaptable to the changing levels of flood risk likely
133 to be faced by future generations. It is also imperative that lessons are shared internationally
134 (Knight et al., 2006), as whilst each city has its own local characteristics, whether physical,
135 social, economic or institutional, cities can learn much from each other's examples, particularly
136 where significant events have recently occurred.

137 In economies experiencing rapid growth it is tempting to reject any measures that might reduce
138 the capacity for economic development, but the potential impact of an event such as Sandy in a
139 city that has not adequately considered these issues could lead to a high loss of life and an even
140 greater impact on economic growth. Flood hazards are increasingly connected to, and can have
141 an impact on the world economy. For example, Chongvilaivan (2012) reported that the 2011
142 Thailand floods indirectly affected a number of their trading partners. Japan's automotive

143 exports industry in particular, experienced a decline of 24.1% in the December following the
144 floods, as Thailand is a major customer for vehicle parts and components. Fujita and Hamaguchi
145 (2012) found similar impacts on the production networks of the automotive industry after the
146 tsunami and catastrophic floods in Japan in March 2011, which recorded an export capacity drop
147 of 39% in China. Such negative impacts in any of the Asian megacity regions would
148 undoubtedly have implications for economies across the globe particularly when they are already
149 in a fragile state.
