14  
15 A shortened version of the title: Socio-demographic drivers of red meat consumption

16  
17 Keywords or phrases: Red meat, socioeconomic factors, demographic factors, environmental  
18 impact, health

19

20 **Abstract**

21 Red and processed meat (RPM) intake varies widely globally. In some high income countries the  
22 last decade has witnessed an overall decline or stabilisation in the consumption of RPM, in contrast  
23 to emerging economies where its consumption continues to increase with rising income and rapid  
24 urbanisation. The production and consumption of RPM have become major concerns regarding the  
25 environmental impacts of livestock in particular, but also because of associations between high  
26 RPM consumption and diet-related non-communicable disease. Therefore it is important to identify  
27 socioeconomic and demographic drivers of the consumption of RPM. This paper explores how  
28 consumption of RPM differs with age, gender, socio-economic status and in different global  
29 contexts. There are some key socioeconomic and demographic patterns in RPM consumption. Men  
30 tend to consume RPM more often and in higher quantities, and there is evidence of a social gradient  
31 in high income countries, with lower socioeconomic groups consuming RPM more often and in  
32 larger quantities. Patterns for consumption with age are less clear cut. It is apparent that consumers  
33 in HICs are still consuming high levels of RPM, although the downward shifts in some socio-  
34 economic and demographic groups is encouraging and suggests that strategies could be developed  
35 to engage those consumers identified as high RPM consumers. In LMICs, RPM consumption is  
36 rising, especially in China and Brazil, and in urban areas. Ways of encouraging populations to  
37 maintain their traditional healthy eating patterns need to be found in low and middle income  
38 countries, which will have health, environmental and economic co-benefits.

39 .

40

41 **Introduction**

42 Meat consumption garners polarising views in terms of its nutritional and environmental impact.  
43 Broadly speaking, the concerns fall into two groups: those associated with the production of meat  
44 consumed by the world's populations today (and projected increases) and those associated with the  
45 health consequences of meat consumption. The drivers of meat consumption are complex and  
46 influenced by an inter-related system of factors including culture<sup>(1,2)</sup>, taste<sup>(3)</sup>, cost<sup>(4)</sup>, religion<sup>(2,5)</sup>,  
47 gender and socioeconomic status (SES)<sup>(6)</sup>.

48

49 **Health consequences of red and processed meat consumption**

50 Concerns associated with the health consequences of red and processed meat (RPM) consumption  
51 focus in particular on the emerging literature on their health effects on some cancers<sup>(7,8)</sup>,  
52 cardiovascular disease<sup>(9,10)</sup>, obesity<sup>(11,12)</sup>, type 2 diabetes<sup>(13)</sup> and antibiotic resistance<sup>(14)</sup>. Some of  
53 these negative health consequences depend on the type of meat. Processed meat includes meat  
54 products that have been modified to change the taste or extend shelf life through curing, smoking,  
55 salting or adding preservatives. Frequently consumed examples are shown in Table 1. The  
56 consumption of processed meats has been associated with all-cause mortality<sup>(15)</sup>, which may  
57 partially result from the higher saturated fats and cholesterol contained in processed meats, but is  
58 most likely due to the processing itself, i.e. salting, curing or smoking. Whilst lengthening shelf life  
59 or improving flavour, processed meats also contain known carcinogenic precursors such as  
60 polycyclic aromatic hydrocarbons, heterocyclic aromatic amines, and nitrosamines<sup>(15)</sup> and they are  
61 high in salt<sup>(16)</sup>. This may shed light on recent research suggesting that processed meat consumption  
62 increases risk of cancer, as eating 50g of processed meat a day increases the chance of developing  
63 colorectal cancer by 18%<sup>(8)</sup>. Indeed large cohort studies and meta-analyses indicate that a high  
64 consumption of processed meat is associated with increased overall mortality, but unprocessed meat  
65 is not<sup>(16)</sup>.

66 **Table 1 here**

67

68 On the other hand, evidence that lean red meats (Table 1) per se are carcinogenic is limited.  
69 It is still widely acknowledged that lean red meat is an important complete protein source, in  
70 addition to contributing to essential micronutrient requirements, particularly iron, zinc and B  
71 vitamins<sup>(17)</sup>. Iron deficiency is the most prevalent micronutrient deficiency in the world, affecting  
72 over 1 billion people and if untreated, it can lead to anaemia, with adolescent girls and women of

73 reproductive age being particularly at risk<sup>(17)</sup>. Balancing these environmental and health tensions is  
74 a challenge for the public's health.

75 This complexity make it particular difficult for consumers to determine whether or not to  
76 include red and processed meat in their diets, and if so, how much to include<sup>(18)</sup>.

### 77 **Environmental sustainability and meat consumption**

78 The environmental sustainability of meat consumption has become a concern globally for several  
79 reasons including resource inputs<sup>(19,20)</sup>, planetary limits<sup>(20-23)</sup>, environmental degradation<sup>(24-26)</sup> and  
80 animal welfare<sup>(6)</sup>. The agri-food sector accounts for over 30% of GHGEs globally and the livestock  
81 sector alone contributes 15% of GHGEs<sup>(23)</sup>. Ruminant meats (beef and lamb) for example have  
82 GHG emissions per g of protein that are 250 times greater than legumes<sup>(22)</sup>. It has been estimated  
83 that halving meat, dairy and eggs consumption in the EU would reduce GHGE by up to 40% and  
84 reduce cropland use for food production by almost a quarter<sup>(27)</sup>. Beef requires much more irrigation  
85 water per kcal eaten compared with other protein sources. However the environmental impact of  
86 red meat depends on the way it is produced, for example, if ruminant animals are grazed on land  
87 unsuitable for crops and fed crop residues, then dairy and meat production can provide  
88 environmental benefits through nutrient recycling<sup>(22)</sup>.

89 Comparisons between vegetarian and meat-based diets have illustrated vast differences in  
90 their environmental impact, with a meat-based diet using almost 3 times more water, 13 times more  
91 fertilizer, and 1.4 times more pesticides than a meat-free diet<sup>(28)</sup>. Animal-based foods also generate  
92 more GHGEs than do plant-based foods, with the exception of fruit and vegetables grown in  
93 greenhouses<sup>(29)</sup>. Food production is the largest contributor of GHGEs in the agri-food system and its  
94 inefficiency is of concern, i.e. intensive livestock farming uses the equivalent of 9kcal of grain to  
95 make 1kcal of beef, a proportion that becomes 4/1 for pork and 2/1 for chicken<sup>(30)</sup>. Hence, the future  
96 sustainability of meat remains one of the biggest challenges for a sustainable agri-food system.

97

### 98 Trends in red and processed meat consumption globally

99 In spite of health and environmental concerns, red meat consumption continues to rise in some parts  
100 of the world, as part of the global transition to a diet high in fat and sugar, increasing meat  
101 consumption and decreasing fruit, vegetables and cereals<sup>(31,32)</sup>, particularly in urban areas due to  
102 changing dietary habits related to rapid urbanisation. Overall, processed meat intakes have been  
103 stable over time on a global level (1990-2010) whereas red meat intake has increased, based on data  
104 synthesised from 113 countries from food balance sheets and food consumption surveys<sup>(33)</sup>. Only in  
105 East Asia has unprocessed red meat intake significantly increased during this period. Country-

106 specific intake varies enormously for both red meats (3.0–124.2 g/day) and processed meats, 2.5–  
107 66.1 g/day<sup>(33)</sup>.

108 In higher income countries such as the UK, consumption remains high, although there have  
109 been shifts in the type of meat consumed<sup>(34)</sup>. Poultry consumption has increased five-fold since the  
110 1960's, probably due to a reduction in the relative price of chicken, whereas consumption of beef  
111 and lamb have declined over the same period<sup>(34)</sup>. As low and middle income countries (LMICs)  
112 grow economically, the consumption of meat increases with available income, leading to vast  
113 disparities in intake between high, middle and lower income populations between and within  
114 countries<sup>(31)</sup>.

115 The average meat consumption globally is 100g/day per person, but this average figure  
116 masks the huge diversity of intakes, particularly between countries. For example, in LICs the  
117 average daily meat consumption is half the global average, whilst it is double that in HICs<sup>(20)</sup>. Of  
118 great concern, is that meat consumption is rising (Figure 1), especially in emerging economies  
119 where consumption was previously low, such as those in South and East Asia. As the global price  
120 of meat has decreased it has become more accessible in LMICs, especially for processed meats of  
121 poor quality.

122

123 **Figure 1 here**

124

125 Globally, the US has the highest consumption. In France meat consumption has been falling  
126 since 2000. Meat consumption in rapidly emerging economies such as Brazil and China has  
127 increased rapidly over the last 30 years, with intakes doubling and tripling respectively<sup>(2)</sup>. On the  
128 African continent, only South Africans have intakes similar to that seen in China. Other sub-  
129 Saharan African countries remain low consumers of red meat. Since the global population is  
130 expected to rise to 9.6 billion by 2050<sup>(35)</sup>, it is predicted that demand for meat and animal products  
131 will continue to rise, causing further environmental concerns.

132

### 133 **Socio-demographic patterns in red and processed meat consumption**

134 Gender differences in red and processed meat consumption

135 Several studies have reported that men consume more RPM than women. For example, data from  
136 the UK's most recent National Diet and Nutrition Survey (NDNS) collected annually between 2008  
137 -2011 highlight differences in consumption of RPM for gender, age and socioeconomic status<sup>(36)</sup>. In  
138 this analysis, men consumed significantly higher ( $p < 0.05$ ) quantities of red and processed meat  
139 (both total g and g/1000kcal consumed) as Table 2 illustrates.

140 **Table 2 here**

141

142 This is supported by analysis conducted by Maguire and Monsivais<sup>(37)</sup>, who also found that  
143 men consume more red and processed meat than women by analysing 3 years of the UK's NDNS  
144 data, based on a combined red and processed meat variable<sup>(37)</sup>. Research conducted in  
145 Nottinghamshire, UK of 842 participants also illustrated differences in meat consumption by  
146 gender; as women were significantly more likely ( $P < 0.01$ ) to consume  $\leq 1$  portion of RPM per day,  
147 compared with men. No other significant relationships in terms of consumption were observed in  
148 this study for age or SES, despite more positive attitudes towards consuming less meat and animal  
149 welfare by older respondents<sup>(6)</sup>. Literature examined from other high income countries within  
150 Europe, for example in Germany, also indicates that men consume more red and processed meat  
151 than women<sup>(38)</sup>. Further afield, the US National Health and Nutrition Examination Surveys  
152 (NHANES) data also illustrates that men consume more of every type of meat than women  
153 ( $P < 0.0005$ ) and highlights an on-going trend of women reducing their consumption of red meat<sup>(39)</sup>.

154 These differences in reported consumption could derive from previously highlighted  
155 differences in attitudes towards eating meat between men and women, possibly connected to greater  
156 motivation regarding personal health or animal welfare concerns of women<sup>(6)</sup>. The sociological  
157 literature highlights a link between perceived 'virulent masculinity' and meat consumption<sup>(39)</sup> and  
158 this, combined with the use by some fast food retailers of gender based advertising strategies which  
159 specifically target male consumers, could contribute to greater consumption and possible over  
160 reporting of meat consumption amongst some men. Of further note in the literature is the link  
161 between vegetarianism and feminism<sup>(40)</sup>, which can be summarised by a strong sense of ethical  
162 consideration towards animals, and is enacted through 'cruelty free consumption' by abstinence of  
163 animal products in the diet<sup>(41)</sup>. These discourses would benefit from further exploration in order to  
164 better understand the relationships which exist between gender and meat consumption, and to  
165 determine whether links exist between red and/or processed meat in particular.

166

167 **Age differences in red and processed meat consumption**

168 Analysis of UK nationally representative NDNS data showed no significant differences in  
169 consumption of red or processed meat between age groups (determined by one-way ANOVA)<sup>(36)</sup>.  
170 However, a statistically significant difference between age groups was observed for total red meat  
171 per 1000 kcal of food energy intake ( $F(3, 2030) = 2.825, p = 0.37$ ). A Tukey post hoc test revealed  
172 that those aged 46-60 years consumed significantly more red meat ( $43.96 \pm 29.84, p = 0.41$ )  
173 compared to younger adults aged 19-30 years ( $38.20, \pm 27.48$ ). This higher consumption in middle

174 age may fall again with further ageing, as illustrated in a recent report which stressed that those over  
175 the age of 65 years eat less RPM than younger respondents in the UK<sup>(34)</sup>, a finding which is  
176 supported by a longitudinal British cohort study evidencing a reduction in meat consumption as  
177 people age<sup>(42)</sup>, which concurred with previous research<sup>(6)</sup>; however young people were also more  
178 likely to report that they do not eat any meat at all<sup>(34)</sup>. Similar contradictions in age related to RPM  
179 consumption were highlighted by Wang et al,<sup>(39)</sup> when analysing several US datasets, in that the  
180 NHANES data showed that meat consumption decreased with age, whereas the more recent  
181 ‘Continuing Survey of Food Intakes by Individuals’ (CSFII) dataset evidenced older groups  
182 consuming more meat.

183 Differing attitudes held by older adults towards the source of their meat and animal welfare  
184 have been highlighted in previous research, which has also noted that those of middle age and  
185 above (>46 years) were more likely to frequently purchase meat considered ‘sustainable’<sup>(6)</sup>. This  
186 may account for some of the reported consumption differences, as older adults in the UK may  
187 remember the experience of food rationing during the Second World War<sup>(6)</sup>. Deteriorating dentition  
188 and a decline in chewing capacity may also play a role in older adults consuming less meat, in  
189 particular red meat which is often tougher to chew than poultry.

190

#### 191 Socio-economic status (SES) differences in red and processed meat consumption

192 The relationship between SES (education, income, occupation) and RPM consumption in high  
193 income settings suggests that higher intakes are evident in low SES groups, although the distinction  
194 between red and processed meats is not clear cut. In the UK, NDNS data indicate a statistically  
195 significant difference in RPM consumption by SES determined between occupational groups for  
196 total red meat ( $F(7, 1993) = 3.93, p < 0.001$ ), processed meat ( $F(7, 1993) = 2.78, p = 0.007$ ), total red  
197 meat per 1000 kcal ( $F(7, 1993) = 4.56, p < 0.001$ ) and processed meat per 1000 kcal ( $F(7, 1993) =$   
198  $3.28, p = 0.002$ ). A Tukey post hoc test revealed patterns that indicate a socio-economic gradient in  
199 consumption of RPM, which was particularly notable by occupational group, as shown in Figure 2.  
200 Those in higher managerial and professional occupations reported consuming significantly less red  
201 meat per 1000 kcal (37.24g,  $\pm 26.32$ ) than those in lower supervisory and technical occupations  
202 (47.35g  $\pm 29.06$ ),  $p = 0.004$  and those in routine occupations (47.65g  $\pm 31.31$ ),  $p = 0.001$ . Similarly,  
203 those in lower managerial and professional occupations and intermediate occupations reported  
204 consuming significantly less red meat per 1000 kcal (40.41g,  $\pm 28.5$ ; 38.02g,  $\pm 25.52$  respectively)  
205 than those in routine occupations (47.65g,  $\pm 31.31$ ),  $p = 0.038$  and  $p = 0.019$  respectively. Those in  
206 higher managerial and professional occupations also reported consuming significantly less  
207 processed red meat per 1000 kcals (8.91g,  $\pm 10.84$ ) than routine occupations (12.37g,  $\pm 13.30$ ),

208 p=0.25. Those in lower supervisory and technical occupations and those in routine occupations  
209 reported consuming significantly more processed red meat (19.12g,  $\pm$ 22.2; 20.98,  $\pm$ 25.88  
210 respectively) than those who have never worked (7.90g,  $\pm$ 12.20), p=0.048 and p=0.008  
211 respectively.

212

213

**Figure 2 here**

214

215 The social gradient highlighted is an important outcome of this analysis, because of the  
216 implications for public health. Maguire and Monsivais<sup>(37)</sup> also present evidence of a social gradient  
217 in intake, with a significant trend across each SES indicator; for example the lowest earning  
218 households consumed 15.7g/day more RPM than the highest earning households, those with no  
219 formal qualifications consumed 21.9g/day more RPM than those with a degree qualification, and  
220 higher managerial and professional occupations consumed 25.5g/day less RPM than those in  
221 routine occupations. A study in France<sup>(43)</sup> also found a positive relationship between low education  
222 level and lower meat intake.

223 Those in higher socioeconomic groups may have a greater awareness of the health  
224 implications associated with over consumption of red and processed meat, which could also lead to  
225 an increased consumption of other more beneficial food groups, for example oily fish or fruit and  
226 vegetables. In the case of fish, although it is a healthier choice, viewing it as an alternative protein  
227 source to meat carries serious implications in terms of supply, as stocks cannot meet current  
228 recommendations<sup>(44)</sup>. Levels of awareness and attitudes towards animal welfare have been shown  
229 in Dutch consumers to influence meat purchasing behaviour in terms of choosing meat which is  
230 ‘organic’ and ‘free range’<sup>(45)</sup>, and interestingly a relationship with SES exists between those  
231 abstaining from meat, as research suggests there is a higher level of education amongst those  
232 choosing to be vegetarian<sup>(46)</sup> and higher meat intake in people with lower SES.<sup>(47)</sup>

233 This concurs with the findings of a study<sup>(2)</sup> synthesising panel data for 120 countries over a  
234 long period (1970-2007) which analysed the link between income and meat consumption. The study  
235 reported that meat consumption is higher initially at higher income levels but then over time, higher  
236 levels of income are associated with lower levels of meat consumption, leading to an inverted U  
237 shaped curve of consumption. This may be explained in part by Bourdieu’s theory of distinction<sup>(48)</sup>  
238 and the ways in which people make decisions about their meat intake may be reflective of their  
239 social standing in society. It could be that when meat is initially an expensive and inaccessible food  
240 it is appealing to those in higher SES groups so they can distinguish themselves from the ‘masses’.

241 As RPM become more accessible to the wider population it then loses its appeal as it is no longer  
242 associated with the ‘taste of luxury’.

243 One powerful determinant of choice in food is cost, and this is likely to play a role in driving  
244 processed meat intake, as it is often cheaper than lean ‘carcass’ meat which will not have had  
245 additional substances added to enhance flavour, increase shelf life or indeed add value for the  
246 producer, as is the case with many processed types of meat. Cost has also been shown to be a factor  
247 inhibiting economically disadvantaged groups from accessing health and sustainable diets in other  
248 research<sup>(4)</sup>. Lower food prices have been linked<sup>(4)</sup> to greater consumption of red meat globally<sup>(3)</sup>.  
249 Altruistic motivations are likely to have an influence on consumers from higher socio-economic  
250 groups consuming less RPM, for example the environmental footprint associated with livestock  
251 production<sup>(26)</sup> or animal welfare concerns.

252

### 253 **Challenges in synthesising red and processed meat consumption data**

254 Despite advances in food consumption and nutrition surveillance research, the ability to identify  
255 trends and associations from the available primary data remains challenging, for several reasons.  
256 Firstly, the need to decide whether to explore food supply data, such as those datasets provided by  
257 the Food and Agricultural organisation of the United Nations (FAO), which indicate quantities of  
258 particular foodstuffs available in specific countries, or to focus on data from national dietary  
259 surveys. Some studies have utilised both types of data<sup>(49)</sup>, but this can make comparisons  
260 problematic, particularly when food wastage is estimated to be one-third for HICs such as the  
261 UK<sup>(50)</sup>. Therefore the NDNS survey, which assesses consumption, provides a more accurate picture,  
262 however, as with all self-reported food consumption data, potential under and over reporting is  
263 acknowledged<sup>(51,52)</sup>.

264 Additionally, there is no clearly agreed definition as to what constitutes ‘processed meat’,  
265 although we have provided a summary in Table 1 of this. The US NHANES currently places cured  
266 meat such as bacon or ham within the ‘fresh meat’ category, unlike the UK and WHO which  
267 considers cured meats such as bacon and ham to be ‘processed meat’. Many studies to date have  
268 conducted analyses by considering both red carcass and processed red and white meat as a single  
269 variable<sup>(37,49)</sup>, despite the very different health outcomes associated with the consumption of  
270 processed meat which are now emerging from the literature<sup>(15)</sup>. Therefore improving data collection  
271 methods and an official agreed definition for what constitutes ‘processed meat’ are essential for the  
272 future understanding of diet and disease associations.

273

274

275

276 **Conclusion**

277 An unprecedented shift in RPM consumption of most individuals in HICs is required to reduce its  
278 environmental and health impacts. There are some key socio economic and demographic patterns in  
279 RPM consumption which can be useful to guide interventions, for example men tend to consume  
280 higher quantities, and the clear social gradient presented with lower SES groups consuming larger  
281 quantities in high income countries. Patterns for consumption with age are less clear cut. It is  
282 apparent that consumers in HICs are still consuming high levels of RPM, although the downward  
283 shifts in some socio-economic and demographic groups is encouraging and suggests that strategies  
284 could be developed to engage those consumers identified as high RPM consumers, in particular  
285 young males and those from lower socioeconomic groups. In LMICs, RPM consumption is rising,  
286 especially in China and Brazil, and in urban areas. Ways of encouraging populations to maintain  
287 their traditional eating patterns need to be found and will have health, environmental and economic  
288 co-benefits.

289 Meat is a heterogeneous commodity in terms of its nutritional value, as processed meats  
290 have the most negative health value, whereas lean red meat is an important source of protein and  
291 micronutrients. Dietary patterns characterized by high RPM consumption tend to be lower in plant  
292 based foods, for example fruit and vegetables<sup>(49)</sup>. The promotion of plant based diets including  
293 protein alternatives (such as beans, pulses, nuts) should be encouraged, as this would have the  
294 advantage of enhancing the healthiness of diets and reducing the environmental consequences of the  
295 agri-food system.

296 Reductions in RPM consumption is unlikely to happen without major policy shifts to  
297 support individuals in making the necessary changes. Any policy solutions need to account for the  
298 multitude of nutritional problems that co-exist in different contexts and the need to provide  
299 supportive environments. Social media campaigns may help to engage a wider audience in some  
300 contexts. Similarly, macro level approaches which have a more direct influence on purchasing  
301 decisions, for example financial incentives, and cost could be modelled to ascertain which particular  
302 RPM products have higher externalised costs to both the environment and public health. Human  
303 health is a stronger motivation to reduce red and processed meat than environmental  
304 sustainability<sup>(6)</sup>. A first step will be for nutritionists and health professionals to raise public  
305 awareness about the link between eating red and processed meat on both health and environmental  
306 sustainability, to build support for further action.

431 **Table 1.** Types of red and processed meats

<b>Type</b>	<b>Description</b>	<b>Food examples</b>
Red meat	Meat from mammals which is higher in myoglobin than a white meat.	Lamb, mutton, beef, pork, veal, goat, horse
Processed meats	Meat products that have been modified to change the taste or extend shelf life through curing (adding salt enriched with nitrates and nitrites), smoking, salting or adding preservatives. Most contain some beef or pork, but may also contain poultry, offal, other red meats, or meat by products.	Ham, sausages, salami, bacon, hot dogs, corned beef, beef jerky, ham, canned meat and meat-based sauces.

432

433

434

435 **Table 2.** Red and processed meat consumption by gender (data from UK National Diet and  
436 Nutrition Survey, 2008-11; n=1959)

	Males	Females
Red meat per 1000 kcal	45.32*	38.38
Total red meat (g)	86.89*	56.76
Processed meat per 1000 kcal	10.97*	9.49
Total processed meat (g)	21.59*	14.00
