# The support of top graded local cohomology modules

Mordechai Katzman, Department of Pure Mathematics, University of Sheffield, United Kingdom. *E-mail*: M.Katzman@sheffield.ac.uk

## 1 Introduction

Let  $R_0$  be any domain, let  $R = R_0[U_1, \dots, U_s]/I$ , where  $U_1, \dots, U_s$  are indeterminates of positive degrees  $d_1, \dots, d_s$ , and  $I \subset R_0[U_1, \dots, U_s]$  is a homogeneous ideal.

The main theorem in this paper is Theorem 2.6, a generalization of Theorem 1.5 in [KS], which states that all the associated primes of  $H := H_{R_+}^s(R)$  contain a certain non-zero ideal  $c(I)$  of  $R_0$  called the “content” of  $I$  (see Definition 2.4.) It follows that the support of  $H$  is simply  $V(c(I)R + R_+)$  (Corollary 1.8) and, in particular,  $H$  vanishes if and only if  $c(I)$  is the unit ideal.

These results raise the question of whether local cohomology modules have finitely many minimal associated primes—this paper provides further evidence in favour of such a result (Theorem 2.10 and Remark 2.12.)

Finally, we give a very short proof of a weak version of the monomial conjecture based on Theorem 2.6.

## 2 The vanishing of top local cohomology modules

Throughout this section  $R_0$  will denote an arbitrary commutative Noetherian domain. We set  $S = R_0[U_1, \dots, U_s]$  where  $U_1, \dots, U_s$  are indeterminates of degrees  $d_1, \dots, d_s$ , and  $R = S/I$  where  $I \subset R_0[U_1, \dots, U_s]$  is an homogeneous ideal. We define  $\Delta = d_1 + \dots + d_s$  and denote with  $\mathcal{D}$  the sub-semi-group of  $\mathbb{N}$  generated by  $d_1, \dots, d_s$ .

For  $t \in \mathbb{Z}$ , we shall denote by  $(\bullet)(t)$  the  $t$ -th shift functor (on the category of graded  $R$ -modules and homogeneous homomorphisms).

For any multi-index  $\lambda = (\lambda^{(1)}, \dots, \lambda^{(s)}) \in \mathbb{Z}^s$  we shall write  $U^\lambda$  for  $U_1^{\lambda^{(1)}} \dots U_s^{\lambda^{(s)}}$  and we shall set  $|\lambda| = \lambda^{(1)} + \dots + \lambda^{(s)}$ .

**LEMMA 2.1** *Let  $I$  be generated by homogeneous elements  $f_1, \dots, f_r \in S$ . Then there is an exact sequence of graded  $S$ -modules and homogeneous homomorphisms*

$$\bigoplus_{i=1}^r H_{S_+}^s(S)(-\deg f_i) \xrightarrow{(f_1, \dots, f_r)} H_{S_+}^s(S) \longrightarrow H_{R_+}^s(R) \longrightarrow 0.$$

**Proof:** The functor  $H_{S_+}^s(\bullet)$  is right exact and the natural equivalence between  $H_{S_+}^s(\bullet)$  and  $(\bullet) \otimes_S H_{S_+}^s(S)$  (see [BS, 6.1.8 & 6.1.9]) actually yields a homogeneous  $S$ -isomorphism

$$H_{S_+}^s(S)/(f_1, \dots, f_r)H_{S_+}^s(S) \cong H_{S_+}^s(R).$$

To complete the proof, just note that there is an isomorphism of graded  $S$ -modules  $H_{S_+}^s(R) \cong H_{R_+}^s(R)$ , by the Graded Independence Theorem [BS, 13.1.6].  $\square$

We can realize  $H_{S_+}^s(S)$  as the module  $R_0[U_1^-, \dots, U_s^-]$  of inverse polynomials described in [BS, 12.4.1]: this graded  $R$ -module vanishes beyond degree  $-\Delta$ . More generally  $R_0[U_1^-, \dots, U_s^-]_{-d} \neq 0$  if and only if  $d \in \mathcal{D}$ .

For each  $d \in \mathcal{D}$ ,  $R_0[U_1^-, \dots, U_s^-]_{-d}$  is a free  $R_0$ -module with base  $\mathcal{B}(d) := (U^\lambda)_{-\lambda \in \mathbb{N}^s, |\lambda| = -d}$ . We combine this realisation with the previous lemma to find a presentation of each homogeneous component of  $H_{R_+}^s(R)$  as the cokernel of a matrix with entries in  $R_0$ .

Assume first that  $I$  is generated by one homogeneous element  $f$  of degree  $\delta$ . For any  $d \in \mathcal{D}$  we have, in view of Lemma 2.1, a graded exact sequence

$$R_0[U_1^-, \dots, U_s^-]_{-d-\delta} \xrightarrow{\phi_d} R_0[U_1^-, \dots, U_s^-]_{-d} \longrightarrow H_{R_+}^s(R)_{-d} \longrightarrow 0.$$

The map of free  $R_0$ -modules  $\phi_d$  is given by multiplication on the left by a  $\#\mathcal{B}(d) \times \#\mathcal{B}(d + \delta)$  matrix which we shall denote later by  $M(f; d)$ .

In the general case, where  $I$  is generated by homogeneous elements  $f_1, \dots, f_r \in S$ , it follows from Lemma 2.1 that the  $R_0$ -module  $H_{R_+}^s(R)_{-d}$  is the cokernel of a matrix  $M(f_1, \dots, f_r; d)$  whose columns consist of all the columns of  $M(f_1, d), \dots, M(f_r, d)$ .

Consider a homogeneous  $f \in S$  of degree  $\delta$ . We shall now describe the matrix  $M(f; d)$  in more detail and to do so we start by ordering the bases of the source and target of  $\phi_d$  as follows. For any  $\lambda, \mu \in \mathbb{Z}^s$  with negative entries we declare that  $U^\lambda < U^\mu$  if and only if  $U^{-\lambda} <_{\text{Lex}} U^{-\mu}$  where “ $<_{\text{Lex}}$ ” is the lexicographical term ordering in  $S$  with  $U_1 > \dots > U_s$ . We order the bases  $\mathcal{B}(d)$ , and by doing so also the columns and rows of  $M(f; d)$ , in ascending order. We notice that the entry in  $M(f; d)$  in the  $U^\alpha$  row and  $U^\beta$  column is now the coefficient of  $U^\alpha$  in  $fU^\beta$ .

**LEMMA 2.2** *Let  $\nu \in \mathbb{Z}^s$  have negative entries and let  $\lambda_1, \lambda_2 \in \mathbb{N}^s$ . If  $U^{\lambda_1} <_{\text{Lex}} U^{\lambda_2}$  and  $U^\nu U^{\lambda_1}, U^\nu U^{\lambda_2} \in R_0[U_1^-, \dots, U_s^-]$  do not vanish then  $U^\nu U^{\lambda_1} > U^\nu U^{\lambda_2}$ .*

**Proof:** Let  $j$  be the first coordinate in which  $\lambda_1$  and  $\lambda_2$  differ. Then  $\lambda_1^{(j)} < \lambda_2^{(j)}$  and so also  $-\nu^{(j)} - \lambda_1^{(j)} > -\nu^{(j)} - \lambda_2^{(j)}$ ; this implies that  $U^{-\nu-\lambda_1} >_{\text{Lex}} U^{-\nu-\lambda_2}$  and  $U^{\nu+\lambda_1} > U^{\nu+\lambda_2}$ .  $\square$

**LEMMA 2.3** *Let  $f \neq 0$  be a homogeneous element in  $S$ . Then, for all  $d \in \mathcal{D}$ , the matrix  $M(f; d)$  has maximal rank.*

**Proof:** We prove the lemma by producing a non-zero maximal minor of  $M(f; d)$ . Write  $f = \sum_{\lambda \in \Lambda} a_\lambda U^\lambda$  where  $a_\lambda \in R_0 \setminus \{0\}$  for all  $\lambda \in \Lambda$  and let  $\lambda_0$  be such that  $U^{\lambda_0}$  is the minimal member of  $\{U^\lambda : \lambda \in \Lambda\}$  with respect to the lexicographical term order in  $S$ .

Let  $\delta$  be the degree of  $f$ . Each column of  $M(f; d)$  corresponds to a monomial  $U^\lambda \in \mathcal{B}(d + \delta)$ ; its  $\rho$ -th entry is the coefficient of  $U^\rho$  in  $fU^\lambda \in R_0[U_1^-, \dots, U_s^-]_{-d}$ .

Fix any  $U^\nu \in \mathcal{B}(d)$  and consider the column  $c_\nu$  corresponding to  $U^{\nu-\lambda_0} \in \mathcal{B}(d + \delta)$ . The  $\nu$ -th entry of  $c_\nu$  is obviously  $a_{\lambda_0}$ .

By the previous lemma all entries in  $c_\nu$  below the  $\nu$ th row vanish. Consider the square submatrix of  $M(f; d)$  whose columns are the  $c_\nu$  ( $\nu \in \mathcal{B}(d)$ ); its determinant is clearly a power of  $a_{\lambda_0}$  and hence is non-zero.  $\square$

**DEFINITION 2.4** *For any  $f \in R_0[U_1, \dots, U_s]$  write  $f = \sum_{\lambda \in \Lambda} a_\lambda U^\lambda$  where  $a_\lambda \in R_0$  for all  $\lambda \in \Lambda$ . For such an  $f \in R_0[U_1, \dots, U_s]$  we define the content  $c(f)$  of  $f$  to be the ideal  $\langle a_\lambda : \lambda \in \Lambda \rangle$  of  $R_0$  generated by all the coefficients of  $f$ . If  $J \subset R_0[U_1, \dots, U_s]$  is an ideal, we define its content  $c(J)$  to be the ideal of  $R_0$  generated by the contents of all the elements of  $J$ . It is easy to see that if  $J$  is generated by  $f_1, \dots, f_r$ , then  $c(J) = c(f_1) + \dots + c(f_r)$ .*

**LEMMA 2.5** *Suppose that  $I$  is generated by homogeneous elements*

$f_1, \dots, f_r \in S$ . Fix any  $d \in \mathcal{D}$ . Let  $t := \text{rank } M(f_1, \dots, f_r; d)$  and let  $I_d$  be the ideal generated by all  $t \times t$  minors of  $M(f_1, \dots, f_r; d)$ . Then  $c(I) \subseteq \sqrt{I_d}$ .

**Proof:** It is enough to prove the lemma when  $r = 1$ ; let  $f = f_1$ . Write  $f = \sum_{\lambda \in \Lambda} a_\lambda U^\lambda$  where  $a_\lambda \in R_0 \setminus \{0\}$  for all  $\lambda \in \Lambda$ . Assume that  $c(I) \not\subseteq \sqrt{I_d}$  and pick  $\lambda_0$  so that  $U^{\lambda_0}$  is the minimal element in  $\{U^\lambda : \lambda \in \Lambda\}$  (with respect to the lexicographical term order in  $S$ ) for which  $a_\lambda \notin \sqrt{I_d}$ . Notice that the proof of Lemma 2.3 shows that  $U^{\lambda_0}$  cannot be the minimal element of  $\{U^\lambda : \lambda \in \Lambda\}$ .

Fix any  $U^\nu \in \mathcal{B}(d)$  and consider the column  $c_\nu$  corresponding to  $U^{\nu-\lambda_0} \in \mathcal{B}(d+\delta)$ . The  $\nu$ -th entry of  $c_\nu$  is obviously  $a_{\lambda_0}$ . Lemma 2.2 shows that, for any other  $\lambda_1 \in \Lambda$  with  $U^{\lambda_1} >_{\text{Lex}} U^{\lambda_0}$ , either  $\nu - \lambda_0 + \lambda_1$  has a non-negative entry, in which case the corresponding term of  $fU^{\nu-\lambda_0} \in R_0[U_1^-, \dots, U_s^-]_{-d}$  is zero, or  $U^\nu > U^{\nu-\lambda_0+\lambda_1}$ .

Similarly, for any other  $\lambda_1 \in \Lambda$  with  $U^{\lambda_1} <_{\text{Lex}} U^{\lambda_0}$ , either  $\nu - \lambda_0 + \lambda_1$  has a non-negative entry, in which case the corresponding term of  $fU^{\nu-\lambda_0} \in R_0[U_1^-, \dots, U_s^-]_{-d}$  is zero, or  $U^\nu < U^{\nu-\lambda_0+\lambda_1}$ .

We have shown that all the entries below the  $\nu$ -th row of  $c_\nu$  are in  $\sqrt{I_d}$ . Consider the matrix  $M$  whose columns are  $c_\nu$  ( $\nu \in \mathcal{B}(d)$ ) and let  $\overline{\phantom{x}} : R_0 \rightarrow R_0/\sqrt{I_d}$  denote the quotient map. We have

$$0 = \overline{\det(M)} = \det(\overline{M}) = \overline{a_{\lambda_0}}^{\binom{d-1}{s-1}}$$

and, therefore,  $a_{\lambda_0} \in \sqrt{I_d}$ , a contradiction.  $\square$

**THEOREM 2.6** *Suppose that  $I$  is generated by homogeneous elements  $f_1, \dots, f_r \in S$ . Fix any  $d \in \mathcal{D}$ . Then each associated prime of  $H_{R_+}^s(R)_{-d}$  contains  $c(I)$ . In particular  $H_{R_+}^s(R)_{-d} = 0$  if and only if  $c(I) = R_0$ .*

**Proof:** Recall that for any  $p, q \in \mathbb{N}$  with  $p \leq q$  and any  $p \times q$  matrix  $M$  of maximal rank with entries in any domain,  $\text{Coker } M = 0$  if and only if the ideal generated by the maximal minors of  $M$  is the unit ideal. Let  $M = M(f_1, \dots, f_r; d)$ , so that  $H_{R_+}^s(R)_{-d} \cong \text{Coker } M$ .

In view of Lemmas 2.3 and 2.5, the ideal  $c(I)$  is contained in the radical of the ideal generated by the maximal minors of  $M$ ; therefore, for each  $x \in c(I)$ , the localization of  $\text{Coker } M$  at  $x$  is zero; we deduce that  $c(I)$  is contained in all associated primes of  $\text{Coker } M$ .

To prove the second statement, assume first that  $c(I)$  is not the unit ideal. Since all minors of  $M$  are contained in  $c(I)$ , these cannot generate the unit ideal and  $\text{Coker } M \neq 0$ . If, on the other hand,  $c(I) = R_0$  then  $\text{Coker } M$  has no associated prime and  $\text{Coker } M = 0$ .  $\square$

COROLLARY 2.7 *Let the situation be as in 2.6. The following statements are equivalent:*

1.  $c(I) = R_0$ ;
2.  $H_{R_+}^s(R)_{-d} = 0$  for some  $d \in \mathcal{D}$ ;
3.  $H_{R_+}^s(R)_{-d} = 0$  for all  $d \in \mathcal{D}$ .

Consequently,  $H_{R_+}^s(R)$  is asymptotically gap-free in the sense of [BH, (4.1)].

COROLLARY 2.8 *The  $R$ -module  $H_{R_+}^s(R)$  has finitely many minimal associated primes, and these are just the minimal primes of the ideal  $c(I)R + R_+$ .*

**Proof:** Let  $r \in c(I)$ . By Theorem 2.6, the localization of  $H_{R_+}^s(R)$  at  $r$  is zero. Hence each associated prime of  $H_{R_+}^s(R)$  contains  $c(I)R$ . Such an associated prime must contain  $R_+$ , since  $H_{R_+}^s(R)$  is  $R_+$ -torsion.

On the other hand,  $H_{R_+}^s(R)_{-\Delta} \cong R_0/c(I)$  and  $H_{R_+}^s(R)_i = 0$  for all  $i > -\Delta$ ; therefore there is an element of the  $(-\Delta)$ -th component of  $H_{R_+}^s(R)$  that has annihilator (over  $R$ ) equal to  $c(I)R + R_+$ . All the claims now follow from these observations.  $\square$

REMARK 2.9 In [Hu, Conjecture 5.1], Craig Huneke conjectured that every local cohomology module (with respect to any ideal) of a finitely generated module over a local Noetherian ring has only finitely many associated primes. This conjecture was shown to be false (cf. [K, Corollary 1.3]) but Corollary 2.8 provides some evidence in support of the weaker conjecture that every local cohomology module (with respect to any ideal) of a finitely generated module over a local Noetherian ring has only finitely many *minimal* associated primes.

The following theorem due to Gennady Lyubeznik ([L]) gives further support for this conjecture:

THEOREM 2.10 *Let  $R$  be any Noetherian ring of prime characteristic  $p$  and let  $I \subset R$  be any ideal generated by  $f_1, \dots, f_s \in R$ . The support of  $H_I^s(R)$  is Zariski closed.*

**Proof:** We first notice that the localization of  $H_I^s(R)$  at a prime  $P \subset R$  vanishes if and only if there exist positive integers  $\alpha$  and  $\beta$  such that

$$(f_1 \cdots f_s)^\alpha \in \langle f_1^{\alpha+\beta}, \dots, f_s^{\alpha+\beta} \rangle$$

in the localization  $R_P$ . This is because if we can find such  $\alpha$  and  $\beta$  we can then take  $q := p^e$  powers and obtain

$$(f_1 \cdots f_s)^{q\alpha} \in \langle f_1^{q\alpha+q\beta}, \dots, f_s^{q\alpha+q\beta} \rangle$$

for all such  $q$ . This shows that all elements in the direct limit sequence

$$R/\langle f_1, \dots, f_s \rangle \xrightarrow{f_1 \cdots f_s} R/\langle f_1^2, \dots, f_s^2 \rangle \xrightarrow{f_1 \cdots f_s} \dots$$

map to 0 in the direct limit and hence  $H_I^s(R) = 0$ .

But if

$$(f_1 \cdots f_s)^\alpha \in \langle f_1^{\alpha+\beta}, \dots, f_s^{\alpha+\beta} \rangle$$

in  $R_P$ , we may clear denominators and deduce that this occurs on a Zariski open subset containing  $P$ .

Thus the complement of the support is a Zariski open subset.  $\square$

It may be reasonable to expect that non-top local cohomology modules might also have finitely many minimal associated primes; the only examples known to me of non-top local cohomology modules with infinitely many associated primes are the following: Let  $k$  be any field, let  $R_0 = k[x, y, s, t]$  and let  $S$  be the localisation of  $R_0[u, v, a_1, \dots, a_n]$  at the maximal ideal  $\mathfrak{m}$  generated by  $x, y, s, t, u, v, a_1, \dots, a_n$ . Let  $f = sx^2v^2 - (t+s)xyuv + ty^2u^2 \in S$  and let  $R = S/fS$ . Denote by  $I$  the ideal of  $S$  generated by  $u, v$  and by  $A$  the ideal of  $S$  generated by  $a_1, \dots, a_n$ .

**THEOREM 2.11** *Assume that  $n \geq 2$ . The local cohomology module  $H_{I \cap A}^2(R)$  has infinitely many associated primes and  $H_{I \cap A}^{n+1}(R) \neq 0$ .*

**Proof:** Consider the following segment of the Mayer-Vietoris sequence

$$\dots \rightarrow H_{I+A}^2(R) \rightarrow H_I^2(R) \oplus H_A^2(R) \rightarrow H_{I \cap A}^2(R) \rightarrow \dots$$

Notice that  $a_1, \dots, a_n, u$  form a regular sequence on  $R$  so  $\text{depth}_{I+A} R \geq n+1 \geq 3$  and the leftmost module vanishes. Thus  $H_I^2(R)$  injects into  $H_{I \cap A}^2(R)$  and Corollary 1.3 in [K] shows that  $H_{I \cap A}^2(R)$  has infinitely many associated primes.

Consider now the following segment of the Mayer-Vietoris sequence

$$\dots \rightarrow H_{I \cap A}^{n+1}(R) \rightarrow H_{I+A}^{n+2}(R) \rightarrow H_I^{n+2}(R) \oplus H_A^{n+2}(R) \rightarrow \dots$$

The direct summands in the rightmost module vanish since both  $I$  and  $A$  can be generated by less than  $n+2$  elements, so  $H_{I \cap A}^{n+1}(R)$  surjects onto  $H_{I+A}^{n+2}(R)$ .

Now  $c(f)$  is the ideal of  $R_0$  generated by  $sx^2, -(t+s)xy$  and  $ty^2$  so  $c(f) \subset \langle x, y \rangle \neq R_0$ . Corollary 2.7 now shows that  $H_{I+A}^{n+2}(R)$  does not vanish and, therefore, nor does  $H_{I \cap A}^{n+1}(R)$ .  $\square$

REMARK 2.12 When  $n \geq 3$ ,  $H_{I+A}^3(R) = 0$  and the argument above shows that  $H_I^2(R) \oplus H_A^2(R) \cong H_{I \cap A}^2(R)$ . Corollary 2.8 implies that  $H_I^2(R)$  has finitely many minimal primes and since the only associated prime of  $H_A^2(R)$  is  $A$ ,  $H_{I \cap A}^2(R)$  has finitely many minimal primes.

When  $n = 2$  we obtain a short exact sequence

$$0 \rightarrow H_I^2(R) \oplus H_A^2(R) \rightarrow H_{I \cap A}^2(R) \rightarrow H_{I+A}^3(R) \rightarrow 0.$$

The short exact sequence

$$0 \rightarrow S \xrightarrow{f} S \rightarrow R \rightarrow 0$$

implies that  $H_{I+A}^3(R)$  injects into the local cohomology module  $H_{I+A}^4(S)$  whose only associated prime is  $I + A$ , so again we see that  $H_{I \cap A}^2(R)$  has finitely many minimal associated primes.

### 3 An application: a weak form of the Monomial Conjecture.

In [Ho] Mel Hochster suggested reducing the Monomial Conjecture to the problem of showing the vanishing of certain local cohomology modules which we now describe.

Let  $C$  be either  $\mathbb{Z}$  or a field of characteristic  $p > 0$ , let  $R_0 = C[A_1, \dots, A_s]$  where  $A_1, \dots, A_s$  are indeterminates,  $S = R_0[U_s, \dots, U_s]$  where  $U_1, \dots, U_s$  are indeterminates and  $R = S/F_{s,t}S$  where

$$F_{s,t} = (U_1 \cdots U_s)^t - \sum_{i=1}^s A_i U_i^{t+1}.$$

Suppose that

$$H_{s,t} := H_{\langle U_1, \dots, U_s \rangle}^s(R)$$

vanishes with  $C = \mathbb{Z}$ . If for some local ring  $T$  we can find a system of parameters  $x_1, \dots, x_s$  so that  $(x_1 \cdots x_s)^t \in \langle x_1^{t+1}, \dots, x_s^{t+1} \rangle$ , i.e., if there exist  $a_1, \dots, a_s \in T$  so that  $(x_1 \cdots x_s)^t = \sum_{i=1}^t a_i x_i^{t+1}$  we can define an homomorphism  $R \rightarrow T$  by mapping  $A_i$  to  $a_i$  and  $U_i$  to  $x_i$ . We can view  $T$  as an  $R$ -module and we have an isomorphism of  $T$ -modules

$$H_{\langle x_1, \dots, x_s \rangle}^s(T) \cong H_{\langle U_1, \dots, U_s \rangle}^s(R) \otimes_R T$$

and we deduce that

$$H_{\langle x_1, \dots, x_s \rangle}^s(T) = 0$$

but this cannot happen since  $x_1, \dots, x_s$  form a system of parameters in  $T$ .

We have just shown that the vanishing of  $H_{s,t}$  for all  $t \geq 1$  implies the Monomial Conjecture in dimension  $s$ . In [Ho] Mel Hochster proved that these local cohomology modules vanish when  $s = 2$  or when  $C$  has characteristic  $p > 0$ , but in [R] Paul Roberts showed that, when  $C = \mathbb{Z}$ ,  $H_{3,2} \neq 0$ , showing that Hochster's approach cannot be used for proving the Monomial Conjecture in dimension 3. This can be generalized further:

**PROPOSITION 3.1** *When  $C = \mathbb{Z}$ ,  $H_{s,2} \neq 0$  for all  $s \geq 3$ .*

**Proof:** We proceed by induction on  $s$ ; the case  $s = 3$  is proved in [R].

Assume that for some  $s \geq 1$ ,  $\alpha \geq 0$  and  $\delta > \alpha$  the monomial  $x_1^\alpha \dots x_{s+1}^\alpha$  is in the ideal of  $C[x_1, \dots, x_{s+1}, a_1, \dots, a_{s+1}]$  generated by  $x_1^{\alpha+\beta}, \dots, x_{s+1}^{\alpha+\beta}$  and  $F_{s+1,t}$ .

Define  $G_{s+1,2}$  to be the result of substituting  $a_{s+1} = 0$  in  $F_{s+1,2}$ , i.e.,

$$G_{s+1,2} = (x_1 \dots x_{s+1})^2 - \sum_{i=1}^s a_i x_i^3.$$

If

$$x_1^\alpha \dots x_{s+1}^\alpha \in \langle x_1^{\alpha+\beta}, \dots, x_{s+1}^{\alpha+\beta}, F_{s+1,2} \rangle \quad (1)$$

then by setting  $a_{s+1} = 0$  we see that

$$x_1^\alpha \dots x_{s+1}^\alpha \in \langle x_1^{\alpha+\beta}, \dots, x_{s+1}^{\alpha+\beta}, G_{s+1,2} \rangle.$$

If we assign degree 0 to  $x_1, \dots, x_s$ , degree 1 to  $x_{s+1}$  and degree 2 to  $a_1, \dots, a_s$  then the ideal  $\langle x_1^{\alpha+\beta}, \dots, x_{s+1}^{\alpha+\beta}, G_{s+1,2} \rangle$  is homogeneous and we must have

$$x_1^\alpha \dots x_{s+1}^\alpha \in \langle x_1^{\alpha+\beta}, \dots, x_s^{\alpha+\beta}, G_{s+1,2} \rangle.$$

If we now set  $x_{s+1} = 1$  we obtain

$$x_1^\alpha \dots x_s^\alpha \in \langle x_1^{\alpha+\beta}, \dots, x_s^{\alpha+\beta}, F_{s,2} \rangle. \quad (2)$$

Now  $H_{s+1,2} = 0$  if and only if for each  $\beta \geq 1$  we can find an  $\alpha \geq 0$  so that equation (1) holds and this implies that for each  $\beta \geq 1$  we can find an  $\alpha \geq 0$  so that equation (2) holds which is equivalent to  $H_{s,2} = 0$ . The induction hypothesis implies that  $H_{s,2} \neq 0$  and so  $H_{s+1,2} \neq 0$ .  $\square$

The local cohomology modules  $H_{s,t}$  are a good illustration for the failure of the methods of the previous section in the non-graded case. For example, one cannot decide whether  $H_{s,t}$  is zero just by looking at  $F_{s,t}$ : the vanishing of  $H_{s,t}$  depends on the characteristic of  $C$ ! Compare this situation to the following graded problem.

**THEOREM 3.2 (A WEAKER MONOMIAL CONJECTURE)** *Let  $T$  be a local ring with system of parameters  $x_1, \dots, x_s$ . For all  $t \geq 0$  we have*

$$(x_1 \cdots x_s)^t \notin \langle x_1^{st}, \dots, x_s^{st} \rangle.$$

**Proof:** Let  $S = \mathbb{Z}[A_1, \dots, A_s][X_1, \dots, X_s]$  where  $\deg A_i = 0$  and  $\deg X_i = 1$  for all  $1 \leq i \leq s$ . Following Hochster's argument we reduce to the problem of showing that

$$H_{\langle X_1, \dots, X_s \rangle}^s(S/fS) = 0$$

where

$$f = (X_1 \cdots X_s)^t - \sum_{i=1}^s A_i X_i^{st}.$$

Since  $f$  is homogeneous and  $c(f)$  is the unit ideal, the result follows from Theorem 2.6.  $\square$
