Abstract:	<p>Background and study aims: Capsule endoscopy is an attractive alternative to colorectal cancer screening by conventional colonoscopy, but is currently limited by compromised mucosal visibility, secondary to an unmet need of safe, controlled colonic insufflation. We have therefore developed a novel system of untethered, wireless controlled carbon dioxide (CO<sub>2</sub>) insufflation for use in colonic capsule endoscopy, which this study aims to assess in-vivo.</p> <p>Subjects and methods: This is an observational study of in-vivo non-survival Yorkshire-Landrace cross swine. After placement of a novel insufflation capsule in the porcine colon, we recorded volume of insufflation, time, force, visualization, and a pathologic assessment of the colon.</p> <p>Results: In-vivo trials demonstrated a mean diameter of insufflation of 32.1±3.9 mm. The volume of CO<sub>2</sub> produced successfully allowed for complete endoscopic visualization of the mucosa and for safe proximal passage of the endoscope. Pathologic examination demonstrated no evidence of trauma secondary to the capsule.</p> <p>Conclusions: These results demonstrate the feasibility of a novel method of controlled colonic insufflation via an untethered capsule in-vivo. This</p>

## Introduction

Colorectal cancer (CRC) is the third most common cancer in both men and women and the second leading cause of cancer death in the United States [1]. CRC is also one of the most preventable as it has a well-defined pre-malignant phase that can be readily detected and removed using endoscopic techniques [2-5]. Colonoscopy remains the “gold standard” for CRC screening due to its safety and effectiveness. Yet its benefits have not been realized by a significant proportion of the population—in 2009 only a little over 60% had received appropriate screening, as compared with breast cancer (more than 70%) or cervical cancer (80% or more) [1]. Many factors may account for this including a disruptive and time consuming process (patients generally have to miss a day of work and must have a companion to assist with transportation back to their residence), the potential for pain, and the small risk of adverse events [6]. Thus there is a clear need for improved and more acceptable methods for CRC screening.

In this regard, capsule endoscopy is a very attractive alternative to colonoscopy, and is now an essential tool for evaluation of patients with suspected small-bowel disorders [7,8]. As technology around small-bowel wireless capsule endoscopy advances, a natural progression has been toward its adaptation for examination of the colon [9]. Unfortunately, in its current embodiment, the sensitivity and specificity for detection of colon lesions is disappointingly low (sensitivity=73%, specificity=89%) [10]. In conventional colonoscopy, visualization of the mucosa is improved by insufflation of the colon; with a positive correlation between luminal distention achieved by insufflation and polyp and adenoma detection rate [11]. One factor contributing to the suboptimal performance of colon capsule endoscopy is partial or incomplete visualization of the mucosa during the exam. Thus, there is a need for similarly safe, controlled, and reliable insufflation in colon capsule endoscopy.

Our team has been working on a highly innovative approach to address this critical technological gap. We have developed a novel device to achieve untethered controlled carbon dioxide (CO<sub>2</sub>) insufflation suitable for capsule endoscopy of the colon: the CO<sub>2</sub>mfort Cap. CO<sub>2</sub> has been advocated as a substitute to traditional room air due to its advantages of reduced post-procedure gas secondary to its rapid absorption, as well as improved patient comfort secondary to an overall decrease in intestinal distention [12,13]. Our seminal reports of this technology provided bench-top and *ex-vivo* demonstration of the ability of the CO<sub>2</sub>mfort Cap to produce adequate CO<sub>2</sub> volumes for complete visualization of the colonic mucosa [14,15]. In this study, we examined the feasibility and safety of this device *in-vivo*.

## Materials and methods

### *Description of CO<sub>2</sub>mfort Cap*

The CO<sub>2</sub>mfort Cap is a novel two-compartment capsule containing reactants that when mixed, yield CO<sub>2</sub>. The basic chemical reaction uses FDA-approved products [16] sodium bicarbonate (NaHCO<sub>3</sub>) and citric acid (C<sub>6</sub>H<sub>8</sub>O<sub>7</sub>) to produce sodium citrate (Na<sub>3</sub>C<sub>6</sub>H<sub>5</sub>O<sub>7</sub>), carbon dioxide (CO<sub>2</sub>), and water (Fig. 1). Fabricated from a polypropylene-like material (Objet DurusWhite RGD430, Billerica, MA, USA), the CO<sub>2</sub>mfort Cap is 12 mm in diameter and 32 mm in length, comparable in dimension to 11 mm x 31 mm Pillcam Colon (Given Imaging, Inc., Yoqneam, Israel). The CO<sub>2</sub>mfort Cap has two separate compartments connected by two magnetic valves (Fig. 2). When activated, the citric acid solution in the upper compartment reacts with the sodium bicarbonate in the lower compartment, producing CO<sub>2</sub> that is released through the exhaust ports along the lower midline of the capsule. Remote triggering is achieved by means of a disc-shaped NdFeB external permanent magnet (EPM) (Sintered NdFeB magnets, B&W Technology and Trade GmbH, Jena, Germany) with a diameter of 50 mm, thickness of 20 mm, and a N52 axial

magnetization.

#### ***Bench-top trials to assess reaction kinetics***

Previous experiments of the chemical reaction were performed at room temperature [18]. To determine the performance at standard body temperature, we conducted ten bench-top trials at 37°C. For each trial, a total of 0.82 grams NaHCO<sub>3</sub> and 0.63 grams C<sub>6</sub>H<sub>8</sub>O<sub>7</sub> were utilized in 0.75 ml water. Measured parameters included: volume of CO<sub>2</sub> produced via the water displacement technique, time to reach 50% of the CO<sub>2</sub> plateau (t<sub>50</sub>), and time to reach the CO<sub>2</sub> plateau (t<sub>plateau</sub>).

#### ***Bench-top trials to assess force generation and safety***

To determine the maximum force that may be exerted on the colon mucosa by the capsule secondary to the magnetic couple between the internal and external magnets, we conducted a simple experiment. A CO<sub>2</sub>mfort Cap was attached to a load cell (Nano 17, ATI Industrial Automation, Apex, NC, USA) and an N52 EPM measuring 50 mm by 20 mm was placed 200 mm above the center of the capsule. As the EPM was moved toward the CO<sub>2</sub>mfort Cap, the force generated by magnetic coupling and the distance between the CO<sub>2</sub>mfort Cap and EPM were recorded.

#### ***In-vivo porcine trials***

Based on our prior *ex-vivo* data, we tested the ability of multiple CO<sub>2</sub>mfort Caps to work in synergy in order to optimize luminal visibility *in-vivo*. Five separate swine each underwent per-rectum placement of three CO<sub>2</sub>mfort Caps. Experiments were performed in five female Yorkshire-Landrace cross swine weighing 30-35 kg. General anesthesia was induced with Telazol (4.4 mg/kg IV, Fort Dodge, Ames, Iowa), xylazine (2.2 mg/kg IV), and ketamine (2.2 mg/kg IV). Following endotracheal intubation and throughout the procedure, the animals were maintained on a semi-closed circuit inhalation of 1% to 3% isoflurane and ventilated.

The three capsules were placed in close enough proximity to allow for simultaneous activation of the reaction by the EPM. All reactions were observed under direct endoscopic visualization (the endoscope was disconnected from air insufflation and suction) and by fluoroscopy for a period of 12 minutes. Fluoroscopic images were acquired to estimate the diameter of the gas column generated (cm) and sustained. These measurements were analyzed by ImageJ software (National Institute of Health, Bethesda, MD, USA). Using the known diameter of the endoscope (GIF 160; Olympus, Tokyo, Japan) of 12.9 mm, the scale was set at 4.496 pixels/mm. The column of CO<sub>2</sub> was modeled as a cylinder, divided into a series of sections at equal intervals, and the diameters were recorded. These were then averaged to estimate the diameter of the gas column generated per trial.

The animal was sacrificed upon procedural completion. The colon was then explanted and examined by an expert gastrointestinal pathologist. The study was approved by the local Institutional Animal Care and Use Committee.

#### ***Statistical Analysis***

All continuous data are reported as mean±standard deviation (SD). Normally distributed continuous variables were analyzed using a *t*-test. ANOVA was utilized to compare bench-top reaction kinetics to *in-vivo* reaction kinetics using Prism6 (GraphPad Software Inc., La Jolla, CA, USA). Statistical significance was set at p<0.05.

## **Results**

### ***CO<sub>2</sub> production reaction is rapid and robust***

We first tested the reaction kinetics and performance characteristics *in vitro*. Bench-top reaction testing at 37°C yielded a mean CO<sub>2</sub> volume of 286.64±11.80 ml at t<sub>50</sub>=1 minute and 509.01±9.35 ml at t<sub>plateau</sub>=12 minutes

***External permanent magnet produces a modest but measurable force on the capsule***

When the distance between the capsule and EPM is 78.7±6.0 mm, the force generated by magnetic coupling is sufficient to overcome the weight of gravity on the capsule. When the distance between the capsule and EPM is reduced to 52.5±2.5 mm, the force generated by the magnet is sufficient to activate the valves. As the distance between the capsule and EPM approaches zero, the force generated by the magnet couple approaches 1.025 N. If this force is distributed across the upper surface of the capsule, as defined by 1/3 of the total surface area, the maximum pressure placed on the colon is 2458.91 pascals (0.025 bar).

***CO<sub>2</sub> production in vivo occurs in a controlled and effective manner***

In all five *in-vivo* porcine trials, the CO<sub>2</sub>mfort Caps were successfully triggered and insufflated the porcine colon without evidence of perforation or free air as demonstrated by fluoroscopy. Fluoroscopic image analysis demonstrated experimental reaction kinetics that were similar to bench-top trials (p=0.28). The maximum insufflation diameter achieved was 32.1±3.9 mm by 540±53.7 seconds (Fig. 3).

***Complete visualization of the colon is safely enabled by the CO<sub>2</sub>mfort Cap***

The lumen distention achieved was sufficient for complete endoscopic visualization of the mucosa and safe proximal passage of the endoscope under direct visualization (Video 1). All swine survived and there were no intra-operative or immediate post-operative adverse events. On gross pathology examination, there was no evidence of perforation and there was no evidence of microscopic trauma in three of five specimens (Table 1). Specimens 2 and 3 each demonstrated a linear red streak that corresponded to mild microscopic sub-mucosal edema and a patchy area of hemorrhage into the lamina propria and submucosa.

**Discussion**

This study has several important results with both technical and clinical implications. We chose to test three CO<sub>2</sub>mfort Caps simultaneously in our *in-vivo* trials as our bench-top data indicated that a single CO<sub>2</sub>mfort Cap produces roughly half a liter of insufflation. We attribute the comparable estimated volume produced by three capsules *in-vivo* to loss of CO<sub>2</sub> via the rectum and absorption by the colon mucosa. Nevertheless, in this manner, we were able to demonstrate that when multiple capsules are used in conjunction, they do not stick together and do not self-activate (as the force between the magnetic sphere and metallic ring is stronger than the force between any adjacent magnet from other nearby capsules). Thus, if further insufflation is needed during endoscopy, our approach provides the possibility of introducing additional capsules per rectum to achieve the desired result.

We have designed the CO<sub>2</sub>mfort Cap flow gate with the capacity to trigger the reaction in aliquots. In order to trigger the reaction, the maximum allowable distance between the EPM and CO<sub>2</sub>mfort Cap internal magnets was 52.5±2.5 mm. Bringing the EPM within this distance from the capsule triggers the reaction by opening the flow gate. When the external magnet is taken away from the capsule, the flow gate closes and the reaction stops. This distance can be easily varied depending on the size and strength of the external magnet utilized. For different patient populations, including obesity, larger external magnets can create a stronger magnetic field to allow for control of the release-trigger. Such a design can assist the physician to optimally control insufflation on an as-needed basis.

1  
2  
3  
4 Although 2-dimensional measurement approximations from the fluoroscopic images do not allow  
5 for an accurate estimate of volume produced per capsule *in vivo*, we were able to demonstrate that  
6 the reaction kinetics based on diameter are similar to bench-top trials for volume. Assuming the  
7 *in-vivo* yield was nonetheless lower than bench-top trials, the CO<sub>2</sub>mfort Cap was interestingly  
8 capable of allowing full mucosal visualization for the duration of the procedure with relatively  
9 little CO<sub>2</sub>.  
10

11  
12 Our system currently has the capacity to exert a maximum pressure of 0.025 bar against the  
13 colonic mucosa. Pressure up to 3 bar result in no mucosal damage to the colon [17]. In this study,  
14 the colons of two of the five swine demonstrated submucosal edema and a patchy area of  
15 hemorrhage into the lamina propria and submucosa (Table 1). The diameters of the linear marks  
16 are congruous to the diameter of the endoscope and are most consistent with trauma secondary to  
17 the endoscope coming in contact with the colon and not due to the CO<sub>2</sub>mfort Cap or the reaction  
18 itself. These findings can also be seen in colonoscopy and are generally not considered clinically  
19 significant.  
20

21  
22 The CO<sub>2</sub>mfort Cap is designed such that as long as the compartments remain tightly sealed, the  
23 shelf-life is theoretically determined by the manufacturer's recommended care of the reactants.  
24 Sigma recommends re-testing sodium bicarbonate (Sigma S5761) every 3 years while citric acid  
25 (Sigma C2404) requires no re-testing. Inadvertent or premature exposure to a strong magnetic  
26 field has the potential to open the flow gate, allowing reactants to mix. Precautions against this  
27 must be taken and are in development (e.g., a shielded container can be used to store the  
28 capsules). Other limitations of our study include the use of an *in vivo* non-survival porcine model  
29 and a small experimental sample size. This design was chosen due to the nature of the study aims:  
30 *in-vivo* feasibility and safety evaluation. We note that just as in conventional colonoscopy,  
31 thorough bowel prep is needed to ensure efficacy of capsule endoscopy utilizing the CO<sub>2</sub>mfort  
32 Cap. Finally, while our prototype was manufactured from a polypropylene-like material due to  
33 ease of availability, the capsule can be readily fabricated out of a biocompatible material such as  
34 polyether ether ketone (PEEK).  
35

36  
37 The CO<sub>2</sub>mfort Cap also has the exciting potential to address another critical need in colon capsule  
38 endoscopy—the ability to be actively propelled along the colon rather than move passively, as  
39 colonic transit time in healthy people can be 20-56 hours [18]. A future direction for our team is  
40 to achieve both insufflation and controllable motion at the same time, as can be obtained with  
41 variations in the design of the magnetically controlled valves.  
42

43  
44 In conclusion, this is the first *in-vivo* demonstration in the literature of a technique that adds an  
45 exciting dimension to colon capsule endoscopy; namely, the ability to distend and visualize the  
46 colon on demand with an untethered approach. Using a highly innovative design, we safely and  
47 reliably remotely triggered a chemical reaction within the CO<sub>2</sub>mfort Cap. This released CO<sub>2</sub> in a  
48 controlled fashion and allowed for clear mucosal visibility with a colonoscope. We envision that  
49 such insufflation may allow for better visualization of colonic lesions and increase the diagnostic  
50 yield of colon capsule endoscopy. These results have important implications for the future of  
51 capsule endoscopy and could potentially be transformative for how we screen patients for CRC.

Peer Review

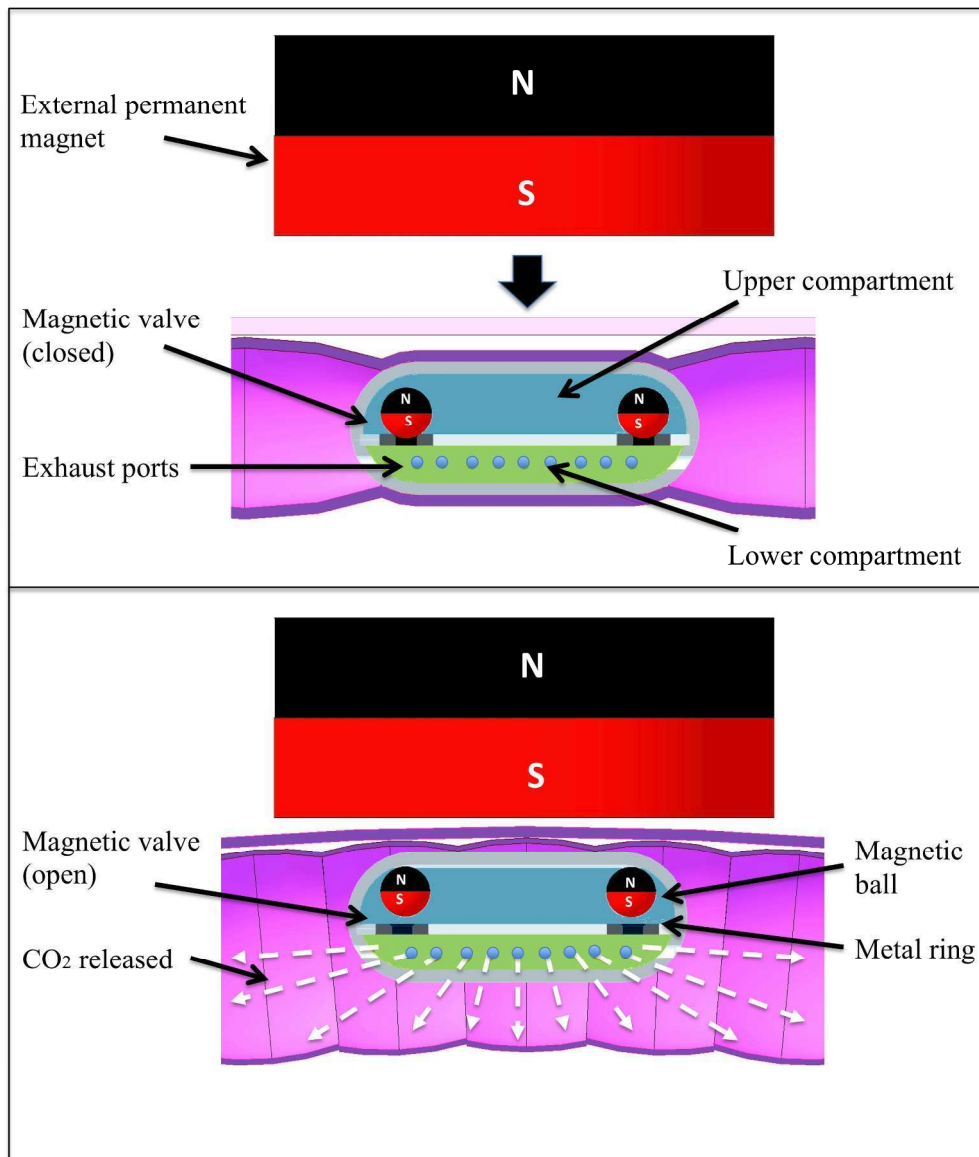

Figure 2. In the CO2mfort Cap's closed configuration, the magnetic valves form a tight barrier between its two compartments. When triggered by an external permanent magnet, the valves open to allow for mixture of the two reactants, producing CO<sub>2</sub> released through exhaust ports along the lining of the lower compartment.

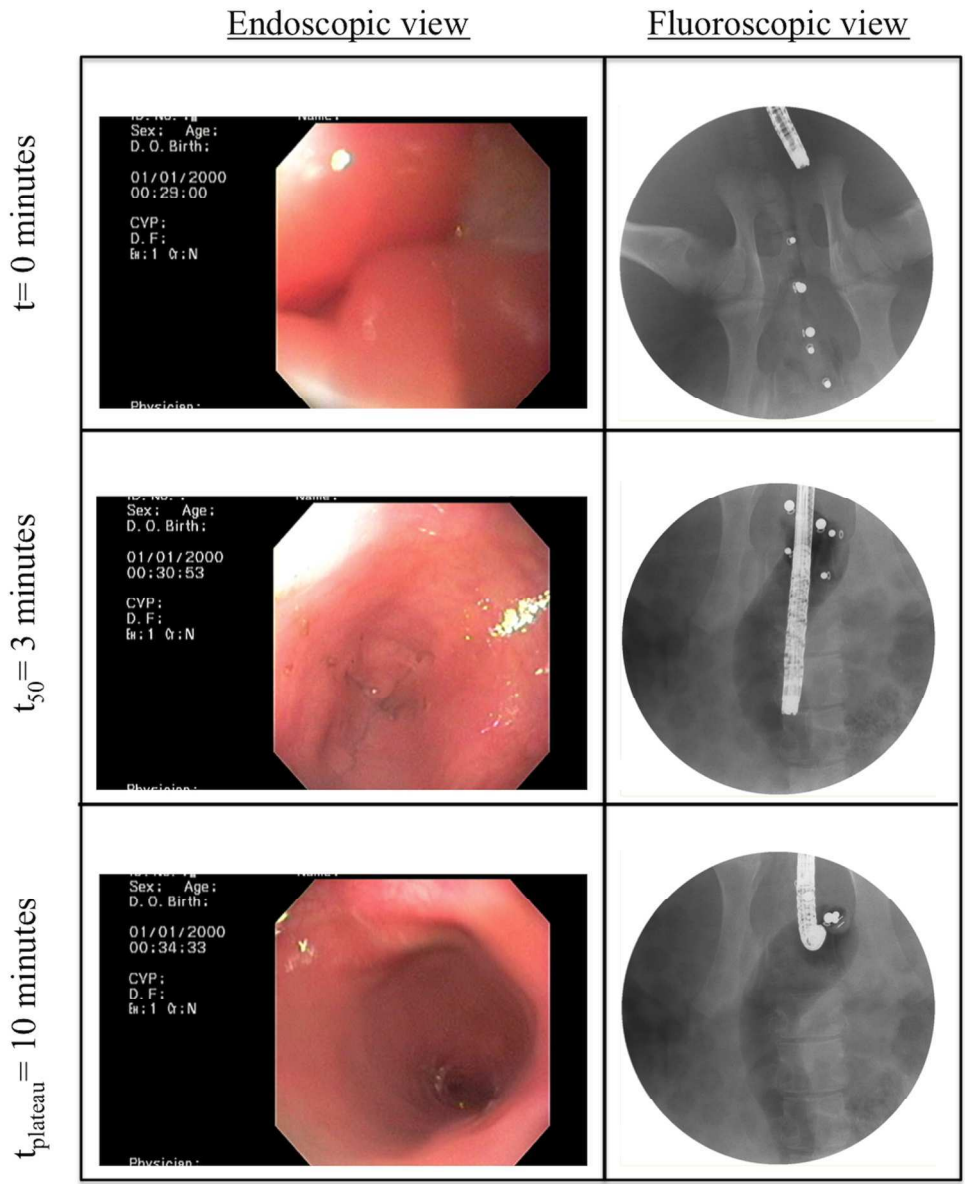

Figure 3. Endoscopic view and corresponding fluoroscopic images over the course of in-vivo trial 3. Fluoroscopic images were acquired and transmitted in real-time to a monitor while endoscopic visualization of the distal colon lumen was performed to confirm mucosal visibility. 152x182mm (300 x 300 DPI)
