## EMOTION PROCESSING &amp; FUNCTIONAL SYMPTOMS

## Abstract

Background: Functional Neurological Symptoms (FNS) are considered non-volitional and potentially highly disabling, but are not explainable by neurological disease or structural abnormalities. Brief Augmented Psychodynamic Interpersonal Therapy (BAPIT), was adapted to treat the putative emotion processing deficits thought to be central to FNS aetiology and maintenance. BAPIT for FNS has previously been shown to improve levels of distress and functioning, but it is unknown whether improvements on such measures correlate with improvements in emotion processing - which this treatment focuses on.

Aim: To determine a) whether the recently developed Emotional Processing Scale-25 can be used to demonstrate BAPIT-associated changes in patients with FNS, and b) whether changes in the EPS-25 are associated with changes in previously validated outcome measures.

Method: 44 patients with FNS completed questionnaires including the EPS-25 and measures of clinical symptomology (health-related quality of life (SF-36), somatic symptoms (PHQ-15), psychological distress (CORE-10), illness understanding (BIPQ)) pre- and post-therapy.

Results: Emotion processing improved following therapy ( $p = .049$ ). Some measures of clinical symptomology also improved,

## EMOTION PROCESSING &amp; FUNCTIONAL SYMPTOMS

1  
2  
3 namely health-related quality of life ( $p = 0.02$ ) and illness  
4  
5 understanding ( $p = 0.01$ ). Improvements in the EPS-25  
6  
7 correlated with improvements in mental health-related quality  
8  
9 of life and psychological distress.  
10

11  
12 Conclusions: Emotion processing and some measures of  
13  
14 clinical symptomology improved in patients with FNS  
15  
16 following BAPIT. The EPS-25 demonstrated changes which  
17  
18 correlated with previously validated outcome measures and  
19  
20 should therefore be suitable as a measure of psychotherapy-  
21  
22 associated change in the FNS patient population.

## EMOTION PROCESSING &amp; FUNCTIONAL SYMPTOMS

Changes in emotion processing following Brief Augmented  
Psychodynamic Interpersonal Therapy for Functional  
Neurological Symptoms

Functional Neurological Symptoms (FNS) are manifestations of altered motor or sensory functions not caused by readily identifiable structural or pathophysiological changes in the nervous system (Carson et al., 2012). The DSM-V refers to FNS as ‘Conversion Disorder’ (American Psychiatric Association, 2013) and the ICD-10 as ‘Somatoform Disorder’ (World Health Organization, 2016). In both nosologies FNS should not be better explained by other known diagnoses. FNS may present as movement disorders, including weakness and tremor. FNS may also affect sensory processing and include symptoms such as anaesthesia or visual deficits. Nonepileptic Attack Disorder (NEAD), is a paroxysmal FNS involving episodes of altered consciousness. Approximately one third of neurology outpatients present with FNS (Stone, 2013). The long-term prognosis is variable but often poor, as FNS are associated with as much or more significant disability, distress, and unemployment as other “medically explained” conditions presenting to neurologists (Carson et al., 2011).

The existing categorization of FNS as a ‘Conversion Disorder’ reflects the on-going assumption that psychological

## EMOTION PROCESSING &amp; FUNCTIONAL SYMPTOMS

1  
2  
3 difficulties may contribute to their aetiology (American  
4  
5 Psychiatric Association, 2013). Indeed, an interaction between  
6  
7 pre-disposing, precipitating, and perpetuating factors linked to  
8  
9 abnormal emotion processing has been proposed as mechanistic  
10  
11 in FNS aetiology (Carson et al., 2012). ‘Emotion processing’  
12  
13 describes the process by which, “emotional disturbances are  
14  
15 absorbed, and decline to the extent that other experiences and  
16  
17 behaviours can proceed without disruption.” (p.51) (Rachman,  
18  
19 1980). According to this model, abnormal emotion processing  
20  
21 occurs when emotional disturbances are not satisfactorily  
22  
23 absorbed by an individual. Disrupted emotion processing may  
24  
25 be evident through direct signs, including intrusive thoughts,  
26  
27 irritability, or inappropriate expressions of emotion. Rachman  
28  
29 argues that there are also ‘indirect’ signs of unsatisfactory  
30  
31 emotion processing, including fatigue, insomnia, and anorexia  
32  
33 (Rachman, 1980). Abnormal emotion processing theoretically  
34  
35 contributes to the symptomatology of multiple mental health  
36  
37 difficulties and personality disorders, including anxiety and  
38  
39 emotionally unstable (borderline) personality disorder (Kret &  
40  
41 Ploeger, 2015).

42  
43  
44  
45  
46  
47  
48 Emotion processing is a multi-faceted concept;  
49  
50 consequently there are multiple instruments measuring different  
51  
52 aspects of emotion processing, such as the Difficulties in  
53  
54 Emotion Regulation Scale (Gratz & Roemer, 2004) and the  
55  
56 Toronto Alexithymia Scale (Bagby, 1994). The Emotional  
57  
58  
59  
60

## EMOTION PROCESSING &amp; FUNCTIONAL SYMPTOMS

1  
2  
3 Processing Scale (EPS-38)(Baker, Thomas, Thomas, & Owens,  
4  
5 2007) was developed to create one unified, psychometrically  
6  
7 sound measurement of emotion processing (Baker et al., 2007).  
8  
9 It has been used to demonstrate improvements in emotion  
10  
11 processing and sensitivity to changes in alexithymia as well as  
12  
13 psychiatric symptom severity following Cognitive Behavioural  
14  
15 Therapy (Baker et al., 2012). The Emotional Processing Scale  
16  
17 (EPS-25) (Baker, Thomas, Thomas, Santonastaso, & Corrigan,  
18  
19 2015) was later created as a shortened version of the EPS-38,  
20  
21 with subscales measuring five key variants of abnormal  
22  
23 emotion processing; namely suppression, signs of unprocessed  
24  
25 emotion, unregulated emotion, avoidance, and impoverished  
26  
27 emotional experience.  
28  
29  
30  
31

32  
33 Several self-report and experimental studies have  
34  
35 provided evidence of abnormal emotion processing in patients  
36  
37 with FNS. This research has primarily focused on NEAD  
38  
39 (Roberts & Reuber, 2014). In a study by Novakova et al.  
40  
41 (Novakova, Howlett, Baker, & Reuber, 2015) patients with  
42  
43 NEAD exhibited greater impairments in emotion processing on  
44  
45 the EPS-25 than healthy controls. Impairments in emotion  
46  
47 processing correlated with more severe somatic symptoms,  
48  
49 greater psychological distress, and a poorer illness  
50  
51 understanding. Another study demonstrated that patients with  
52  
53 NEAD have greater difficulty in describing and identifying  
54  
55 their emotions as well as possessing more negative beliefs  
56  
57  
58  
59  
60

## EMOTION PROCESSING &amp; FUNCTIONAL SYMPTOMS

1  
2  
3 about emotions than healthy controls (Urbanek, Harvey,  
4 McGowan, & Agrawal, 2014). Abnormal attentional biases to  
5 emotional information and altered physiological markers of  
6 autonomic arousal are also evident in this population (Bakvis et  
7 al., 2009). Likewise, disrupted emotion processing is evident in  
8 patients with functional motor symptoms. Using event-related  
9 fMRI, Aybek et al. demonstrated an increased amygdala  
10 response amplitude to fearful imagery, suggesting altered  
11 emotion regulation (Aybek et al., 2015). Furthermore, patients  
12 with such symptoms have greater difficulty in identifying and  
13 describing emotions than controls (Demartini et al., 2014).  
14 Patients with functional motor symptoms also have lower  
15 interoceptive accuracy than healthy controls, elucidating a  
16 mechanism by which difficulties in emotion identification and  
17 processing could manifest (Ricciardi et al., 2015). Given the  
18 multiple forms of emotion processing impairments that have  
19 been identified in the FNS population, the administration of a  
20 single questionnaire in clinical or research settings may  
21 therefore be an efficient approach to capturing the range of  
22 emotional difficulties in this population.  
23

39  
40  
41  
42  
43  
44  
45  
46

47  
48 The putative links between abnormal emotion  
49 processing and FNS suggest that patients could benefit from  
50 psychotherapeutic interventions aiming to improve emotion  
51 processing. Indeed, there is some evidence that Psychodynamic  
52 Interpersonal Therapy (PIT) can help patients with FNS; a brief  
53  
54  
55  
56  
57  
58  
59  
60

## EMOTION PROCESSING &amp; FUNCTIONAL SYMPTOMS

1  
2  
3 course of PIT was effective in a randomised control trial of  
4  
5 patients with ‘multisomatoform disorder’ which included at  
6  
7 least one FNS (Sattel et al., 2012). Brief Augmented  
8  
9 Psychodynamic Interpersonal Therapy (BAPIT), is an  
10  
11 augmented version of traditional PIT, with elements of somatic  
12  
13 trauma therapy. BAPIT was adapted specifically to address  
14  
15 FNS (Howlett & Reuber, 2009; Sattel et al., 2012) and assumes  
16  
17 that psychological difficulties result from interpersonal  
18  
19 conflicts in early life. Deep-rooted and commonly occurring  
20  
21 issues in this population, such as childhood trauma or neglect  
22  
23 are addressed (Reuber, Howlett, Khan, & Grunewald, 2007).  
24  
25 The therapeutic targets of BAPIT include deficits in emotion  
26  
27 processing (including the naming, tolerance, and expression of  
28  
29 emotions) thought to play a role in FNS aetiology. BAPIT has  
30  
31 been associated with significant improvements in psychological  
32  
33 distress, mental health, physical health, and healthcare  
34  
35 utilization in patients with FNS (Reuber, Burness, Howlett,  
36  
37 Brazier, & Grunewald, 2007). In patients with NEAD, BAPIT  
38  
39 has also been associated with sustained improvements in  
40  
41 seizure control and healthcare utilisation (Mayor, Howlett,  
42  
43 Grunewald, & Reuber, 2010). However, whilst BAPIT aims to  
44  
45 improve emotion processing, it has not yet been examined  
46  
47 whether the treatment-associated improvements in outcome  
48  
49 measures are associated with similar improvements in emotion  
50  
51 processing. What is more, the EPS-25 is a novel questionnaire,  
52  
53  
54  
55  
56  
57  
58  
59  
60

## EMOTION PROCESSING & FUNCTIONAL SYMPTOMS

1  
2  
3 and it has not yet been demonstrated whether it is sensitive to  
4  
5 therapy-associated changes in emotion processing in the FNS  
6  
7 population.  
8  
9

10  
11 The aim of the present study was therefore to explore  
12  
13 whether emotion processing as measured by the EPS-25  
14  
15 improved following a course of BAPIT. We also aimed to see  
16  
17 whether changes seen in health-related quality of life (HRQoL)  
18  
19 and some measures of relevant clinical symptomology  
20  
21 (psychological distress, illness understanding, and somatic  
22  
23 symptoms) correlated with changes in the EPS-25 scores.  
24  
25 Finally, we aimed to see whether EPS-25 change scores were  
26  
27 sensitive to changes in the measures of clinical symptomology  
28  
29 used in this study. Given the theorised causal links between  
30  
31 abnormal emotion processing and FNS, we predicted that  
32  
33 patients would experience therapy-associated improvements in  
34  
35 emotion processing, HRQoL, and clinical symptomology. We  
36  
37 also predicted that changes in EPS-25 scores would correlate  
38  
39 with changes in measures of HRQoL and measures of clinical  
40  
41 symptomology.  
42

57  
58  
59  
60

## EMOTION PROCESSING &amp; FUNCTIONAL SYMPTOMS

research departments of the Sheffield Teaching Hospitals Foundation Trust and the Barnsley Hospital NHS Foundation Trust.

**Participants**

Patients with FNS were recruited consecutively from referrals to Neurology Psychotherapy Services at the Barnsley Hospital and the Royal Hallamshire Hospital. The FNS diagnosis was formulated by Consultant Neurologists on the basis of all available clinical information. Neurologists were sufficiently certain about this diagnosis to recommend psychological treatment and withdraw treatment for alternative neurological diagnoses (e.g. antiepileptic drugs). All patients provided written informed consent.

**Treatment**

BAPIT is based on an adapted version of PIT (Hobson, 1985), which assumes that dysfunctional interpersonal patterns originating from childhood are mechanistic in the development of abnormal emotion processing. We have described this approach in greater detail elsewhere (Howlett & Reuber, 2009). BAPIT is intended to improve emotion processing, increase symptom control, change illness perceptions, and improve quality of life through increasing independence and encouraging self-care. In view of the heterogeneous predisposing, precipitating, and perpetuating factors contributing

## EMOTION PROCESSING &amp; FUNCTIONAL SYMPTOMS

1  
2  
3 to the aetiology of FNS, BAPIT is based on a personalised  
4 assessment of each patient and can also include elements  
5 traditionally associated with Cognitive Behavioural Therapy  
6 such as goal-setting, exposure, and relaxation. If the patient has  
7 problems with hyper- or hypo-arousal (often occurring in the  
8 context of a trauma history), elements of Somatic Trauma  
9 Therapy, designed to allow patients to control autonomic  
10 arousal, identify personal triggers, and process traumatic  
11 memories, are incorporated (Rothschild, 2000). Help from  
12 carers may be recruited if appropriate (Howlett & Reuber,  
13 2009).

20  
21  
22  
23  
24  
25  
26  
27  
28 In practice, therapists employ 'here and now'  
29 techniques to help the patient notice, tolerate, and understand  
30 emotions arising in the session. The patient is encouraged to  
31 stay with emotions as they manifest, notice their location in the  
32 body, and describe what they feel as a way of linking the  
33 emotion to associated physical symptoms / sensations e.g., "I  
34 wonder where you can feel that anger in your body right now?"  
35 Linking hypotheses are used to connect between current and  
36 other feelings both inside and outside the therapy room e.g.,  
37 "You say you're feeling angry and frustrated now. I wonder if  
38 that's a bit like you used to feel as a child when that teacher  
39 showed you up in front of the class?"

58 Psychotherapy duration was tailored to the patients' needs but  
59  
60

## EMOTION PROCESSING &amp; FUNCTIONAL SYMPTOMS

1  
2  
3 was intended to be brief (with a notional maximum number of  
4  
5 20 sessions). The initial session lasted two hours. All remaining  
6  
7 sessions lasted 50 minutes. Progress was reviewed after six-  
8  
9 eight sessions. Further sessions were offered if the patient was  
10  
11 considered to have engaged with therapy and if there was a  
12  
13 therapeutic need for further sessions agreed upon by both the  
14  
15 patient and the therapist. The end of therapy was agreed upon  
16  
17 between the two parties when the 20-session limit was reached  
18  
19 or when both parties agreed that therapy was complete (in four  
20  
21 cases, the therapy was extended beyond 20 sessions because of  
22  
23 individual patients' particular needs and circumstances).  
24  
25  
26  
27

**Design and procedure**

28  
29  
30 This was a prospective, uncontrolled study with a  
31  
32 within-subjects design. Study information was sent to patients  
33  
34 along with their first psychotherapy assessment appointment  
35  
36 letter. FNS diagnosis was re-explained at assessment. Patients  
37  
38 were screened for factors suggesting they should be excluded  
39  
40 from outpatient psychotherapy at this point (including risk of  
41  
42 suicide, serious psychiatric conditions or current addictions).  
43  
44 Patients were then given a range of symptom-appropriate self-  
45  
46 help strategies, a relaxation CD, and self-help literature.  
47  
48 Patients were telephoned to check whether their symptoms  
49  
50 persisted and to arrange regular therapy sessions two months  
51  
52 from assessment. Pre-intervention questionnaires were posted  
53  
54 along with the appointment letter to those who agreed to further  
55  
56  
57  
58  
59  
60

## EMOTION PROCESSING &amp; FUNCTIONAL SYMPTOMS

1  
2  
3 sessions. Patients were asked to return the questionnaire battery  
4  
5 in a pre-paid envelope. Patients failing to do so were given an  
6  
7 opportunity to complete the pre-intervention questionnaires  
8  
9 immediately before the first therapy session. The first therapy  
10  
11 session took place approximately three months after the initial  
12  
13 assessment visit.  
14  
15

16  
17 Immediately after discharge (either planned or  
18  
19 following a failure to attend and contact), participants were sent  
20  
21 a post-intervention self-report questionnaire battery to complete  
22  
23 and return using a pre-paid envelope. To reduce attrition,  
24  
25 participants were mailed another copy of the questionnaires if  
26  
27 they had failed to return the initial post-intervention  
28  
29 questionnaires. Pre- and post-intervention data were collected  
30  
31 by an assistant who had not been involved in the administration  
32  
33 of psychotherapy. Patients who did not complete and return the  
34  
35 post-intervention questionnaire pack were classified as ‘study  
36  
37 non-completers’ and excluded from the analysis.  
38  
39  
40  
41

**Measures**

42  
43 Demographic, referral and psychotherapy  
44  
45 questionnaires.  
46  
47  
48

49  
50 Demographic and clinical information was provided by  
51  
52 patients, referring neurologists, and the psychotherapist.  
53  
54 Information regarding the FNS diagnosis was provided by the  
55  
56 neurologist. Personal information was provided by the  
57  
58  
59  
60

## EMOTION PROCESSING &amp; FUNCTIONAL SYMPTOMS

1  
2  
3 participant. An 'end of therapy summary' including  
4  
5 information about the number of sessions, reason for the end of  
6  
7 therapy, and the issues tackled in therapy was provided by the  
8  
9 psychotherapist.  
10

11  
12  
13 ***The Emotional Processing Scale (EPS-25).***  
14

15  
16 The EPS-25 is a standardised 25-item self-report scale  
17  
18 measuring emotion processing styles and deficits. There are  
19  
20 five subscales: suppression, signs of unprocessed emotions,  
21  
22 unregulated emotion, avoidance, and impoverished emotional  
23  
24 experience (Baker et al., 2009). The EPS-25 has been used in  
25  
26 patients with lower back pain (Esteves, Wheatley, Mayall, &  
27  
28 Abbey, 2013), Post-Traumatic Stress Disorder (Compare et al.,  
29  
30 2012), and patients with NEAD (Novakova et al., 2015) but not  
31  
32 in a sample of patients with mixed FNS. Responses are given  
33  
34 on a 0-9 Likert scale. There are also three open-ended  
35  
36 questions. Higher scores indicate greater difficulties with  
37  
38 emotion processing. As per the administrator's manual, single  
39  
40 missing items were replaced by the mean of the subscale  
41  
42 (Baker et al., 2015).  
43  
44  
45  
46  
47

48  
49  
50 ***The Short Form- 36 (SF-36).***  
51

52  
53 The SF-36 is a standardised 36-item self-report  
54  
55 questionnaire that measures nine areas of Health Related  
56  
57 Quality of Life (HRQoL): physical functioning, role limitation  
58  
59 - physical, role limitation - emotional, general health, mental  
60

## EMOTION PROCESSING &amp; FUNCTIONAL SYMPTOMS

1  
2  
3 health, bodily pain, vitality, health transition, and social  
4  
5 functioning. Responses are given on scales ranging from three  
6  
7 to ten options. Higher scores indicate a better HRQoL. Missing  
8  
9 items were dealt with as recommended by the user manual  
10  
11 (Ware, Kosinski, & Gandek, 2000). Remaining scores were  
12  
13 recoded and standardised using norm-based scoring. Scores  
14  
15 were combined into physical (PHS) and mental health (MHS)  
16  
17 summary scales, as per the procedure detailed in the manual.  
18  
19

***Clinical Outcome in Routine Evaluations (CORE-10).***

20  
21  
22  
23  
24  
25 The CORE-10, is a standardised ten-item self-report  
26  
27 scale measuring global psychological distress, taken from the  
28  
29 34 item CORE-OM (Outcome Measure)(Connell & Barkham,  
30  
31 2007). It has been used in studies of patients with FNS (Reuber,  
32  
33 Burness, et al., 2007). On a Likert scale (0-4), higher responses  
34  
35 indicate a higher level of psychological distress experienced  
36  
37 over the last week. The CORE-10 is known to correlate  
38  
39 strongly with the Beck Depression Inventory (Beck, Erbaugh,  
40  
41 Ward, Mock, & Mendelsohn, 1961; Connell & Barkham,  
42  
43 2007).  
44  
45

***Patient Health Questionnaires (PHQ-15).***

46  
47  
48  
49 The PHQ-15 is a standardised 15-item self-report  
50  
51 questionnaire designed to measure common somatic symptoms,  
52  
53 e.g. stomach pain or trouble sleeping (Kroenke, Spitzer, &  
54  
55 Williams, 2002). Participants indicate how bothered they have  
56  
57  
58  
59  
60

## EMOTION PROCESSING &amp; FUNCTIONAL SYMPTOMS

1  
2  
3 been by a symptom over the past week, on a three-point Likert  
4  
5 scale. Higher scores indicate that participants have been  
6  
7 bothered more by a particular symptom. A pattern of missing  
8  
9 items emerged, whereby items 4 and 11 were not responded to  
10  
11 by 14 and 8 participants respectively. These items may not  
12  
13 have been relevant to the participants and so were dropped  
14  
15 from the analysis, replicating the procedure adopted in a  
16  
17 previous paper (Novakova et al., 2015).  
18  
19

***Brief Illness Perception Questionnaire (BIPQ).***

20  
21  
22  
23  
24  
25 The BIPQ is a standardised nine-item self-report scale  
26  
27 measuring emotional and cognitive representations of illness  
28  
29 (Broadbent, Petrie, Main, & Weinman, 2006). For eight items,  
30  
31 participants respond on a 0-10 Likert Scale. The 9<sup>th</sup> item is an  
32  
33 open-ended question. The items represent nine dimensions of  
34  
35 illness perception including consequences, personal control,  
36  
37 treatment control, timeline, illness concern, coherence, identity,  
38  
39 emotional representation, and causation. Responses were  
40  
41 scored and missing items were dealt with as per the scoring  
42  
43 instructions.  
44  
45

**Statistical analysis**

46  
47  
48  
49  
50 Data were analysed using SPSS Version 22.0 (IBM  
51  
52 Corp, 2013). Prior to the use of inferential statistics, all scales  
53  
54 scores were screened for normality. The EPS-25 and SF-36  
55  
56 scale scores were non-normally distributed. Therefore, all  
57  
58  
59  
60

## EMOTION PROCESSING &amp; FUNCTIONAL SYMPTOMS

1  
2  
3 analyses of scale scores were bootstrapped using 95%  
4  
5 confidence intervals based on 1000 samples to control for non-  
6  
7 normality. The  $p$  value was set at  $p = 0.05$  (two-tailed  
8  
9 hypothesis). Otherwise, the inflated risk of Type 1 error  
10  
11 associated with multiple comparisons was controlled for using  
12  
13 the Holm-Bonferroni method to correct  $p$  values when more  
14  
15 than one comparison or correlation was being made.  
16  
17

18  
19 Repeated measures ANOVAs with Bonferroni  
20  
21 corrections were used to compare group mean scores on the  
22  
23 EPS-25 and SF-36 self-report scales pre- versus post-  
24  
25 intervention. The ANOVA model is robust to violations of  
26  
27 normality when group sizes are equal, as is the case in the  
28  
29 present study (Field, 2013). Change scores were calculated  
30  
31 such that positive values corresponded to improvements in  
32  
33 functioning across all scales. Pearson's product moment  
34  
35 correlation coefficients were used to calculate the relationship  
36  
37 between change scores on the EPS-25 and the other clinical  
38  
39 variables. Partial correlation coefficients were used to explain  
40  
41 the amount of variance shared between EPS-25 change scores  
42  
43 and any significantly correlated clinical symptomology /  
44  
45 HRQoL scores.  
46  
47  
48  
49

### 50 51 3.2. Internal consistency of the Emotion Processing Scale- 25

52  
53 Responses on the EPS-25 were combined into total  
54  
55 scores for pre- and post-intervention and assessed for internal  
56  
57 consistency reliability. Internal consistency was excellent when  
58  
59  
60

## EMOTION PROCESSING &amp; FUNCTIONAL SYMPTOMS

administered both before ( $\alpha = .962$ ) and after ( $\alpha = .967$ )  
intervention.

## Results

### Patient characteristics

One hundred and eighteen patients consented to the study. Of this group, 72 returned the pre- and 44 also the post-intervention questionnaire (Figure 1). The final sample therefore consisted of 44 patients. 77.3% (34) were female and the mean age was 41.5 years ( $SD = 13.5$ ). 63% of the sample were economically inactive (defined as unemployed, in receipt of disability benefits, or being retired due to ill-health or old age). Mean symptom duration was 5.4 years ( $SD = 10.8$ ). The mean time between completion of the pre- and post-intervention questionnaires was 11.0 months.

Patients had different main FNS. To explore the justification of analysing patients with different FNS together, we divided the total group into two subgroups (NEAD and 'other FNS'). We compared these two groups on key demographic and therapy variables. There were no differences between the two groups on the mean number of sessions they completed, the number who completed therapy, economic activity, gender, and age at the start of therapy (Supplementary

## EMOTION PROCESSING &amp; FUNCTIONAL SYMPTOMS

1  
2  
3 Table 1). Mean pre-intervention total EPS-25 scores did not  
4  
5 differ between these FNS groups;  $t(42) = .11, p = .91, 95\% \text{ CI}$   
6  
7  $[-1.17, 1.49]$ .  
8  
9

10  
11 The patient sample also included those who had  
12 completed therapy in the judgement of the therapist ( $n = 26$ )  
13 and those who had not ( $n = 17$ ). Reasons for non-completion of  
14 therapy included therapy was non-appropriate ( $n = 2$ ), the  
15 patient was not progressing ( $n = 2$ ), the patient improved after  
16 the initial session ( $n = 1$ ), the patient dropped out ( $n = 9$ ), and  
17 'other' ( $n = 2$ ). To explore the justification of including both  
18 patients who completed therapy and those who did not in the  
19 analysis, both groups of patients were compared on baseline  
20 emotion processing and clinical symptomology (Supplementary  
21 Table 2). There were no differences between the two groups on  
22 any of these measures.

## EMOTION PROCESSING &amp; FUNCTIONAL SYMPTOMS

1  
2  
3 Patients' pre-intervention EPS-25 scores indicated  
4 levels of emotion processing problems above normative healthy  
5 values for the UK, with the mean total EPS-25 scores of the  
6 FNS sample falling within the top 25<sup>th</sup> percentile of normative  
7 values, and well within pain and mental health norms ( $M =$   
8  $4.96$ ,  $SD = 2.26$ ) (Baker et al., 2015). This indicates that  
9 emotion processing problems were common in this patient  
10 group before the intervention.  
11  
12  
13  
14  
15  
16  
17  
18  
19

20  
21 The EPS-25 total score and subscale scores were lower  
22 post-intervention (Table 1). A two-way repeated measures  
23 ANOVA with time point (pre- and post-intervention) and EPS-  
24 25 subscale (suppression, unprocessed emotion, unregulated  
25 emotion, avoidance, and impoverished emotional experience)  
26 as the within-subjects factors showed that there was a  
27 significant main effect of time point;  $F(1,43) = 4.09$ ,  $p = .049$ ,  
28  $\eta_p^2 = 0.09$ , indicating that emotion processing improved  
29 significantly post-intervention. There was also a significant  
30 main effect of subscale;  $F(4,172) = 10.13$ ,  $p < .001$ ,  $\eta_p^2 = 0.19$ ,  
31 suggesting that the mean scores on each subscale differed from  
32 each other both pre- and post-intervention. There was no  
33 significant interaction between time point and subscale,  
34 indicating that the relationship between the mean subscale  
35 scores did not vary over time;  $F(4,172) = 0.923$ ,  $p = 0.45$ ,  $\eta_p^2 =$   
36

## EMOTION PROCESSING &amp; FUNCTIONAL SYMPTOMS

0.02. Therefore, as measured by the EPS-25, emotion processing improved following BAPIT.

[TABLE 1]

**Treatment-associated changes in routine outcome measures**

HRQoL improved following intervention. The post-intervention PHS score ( $M = 38.10$ ,  $SD = 11.95$ ) was greater than the pre-intervention PHS score ( $M = 36.24$ ,  $SD = 11.45$ ). Likewise, the post-intervention MHS score ( $M = 42.31$ ,  $SD = 11.12$ ) was greater than the pre-intervention MHS score ( $M = 40.10$ ,  $SD = 10.11$ ). A two-way repeated measures ANOVA conducted on the SF-36 summary scales (PHS and MHS) with time point (pre- and post-intervention) as the within-subjects factors showed a significant main effect of time point, indicating that SF-36 scores were significantly higher (better quality of life) for both the MHS and PHS scores post-intervention;  $F(1,38) = 5.94$ ,  $p = .02$ ,  $\eta_p^2 = 0.14$ . There was no significant main effect of SF-36 summary scale;  $F(1,38) = 2.69$ ,  $p = 0.11$ ,  $\eta_p^2 = 0.07$ . There was no significant interaction effect;  $F(1,38) = .018$ ,  $p = 0.89$ ,  $\eta_p^2 = .00$ .

Post-intervention BIPQ scores ( $M = 48.83$ ,  $SD = 15.79$ ) were lower than pre-intervention scores ( $M = 55.51$ ,  $SD = 11.84$ ). This improvement in illness understanding was significant;  $t(32) = 2.95$ ,  $p = .01$ , 95% CI [2.57, 12.39]. While

## EMOTION PROCESSING &amp; FUNCTIONAL SYMPTOMS

1  
2  
3 CORE-10 scores were also lower post-intervention ( $M = 17.05$ ,  
4  
5  $SD = 10.43$ ) than pre-intervention ( $M = 19.19$ ,  $SD = 9.39$ ), this  
6  
7 reduction in psychological distress was not statistically  
8  
9 significant;  $t(42) = 1.54$ ,  $p = 0.13$ , 95% CI [-.69, 4.76].  
10  
11 Similarly, while PHQ-15 scores were lower post-intervention  
12  
13 ( $M = 12.14$ ,  $SD = 6.32$ ) than pre-intervention ( $M = 14.05$ ,  $SD =$   
14  
15  $5.35$ ), reductions in the number and severity of somatic  
16  
17 symptoms only approached significance following Holm-  
18  
19 Bonferroni correction;  $t(36) = 0.231$ ,  $p = 0.03$ , 95% CI [.35,  
20  
21 3.43].  
22  
23  
24  
25

26 **Did treatment-associated changes on the EPS-25 correlate**  
27  
28 **with changes in treatment outcome measures?**  
29  
30

31 To assess whether the EPS-25 was sensitive to the  
32  
33 measures of clinical symptomology and HRQoL of life used in  
34  
35 this study, a series of correlational analyses were conducted on  
36  
37 the scale change scores (Table 2). There were moderate to  
38  
39 strong positive correlations between EPS-25 change scores,  
40  
41 CORE-10, and MHS scale change scores. However, there were  
42  
43 no significant correlations between EPS-25 change scores,  
44  
45 PHQ-15 scores, BIPQ scores or PHS change scores. This  
46  
47 suggests that improvements in emotion processing were  
48  
49 associated with improvements in psychological distress and  
50  
51 mental HRQoL, but not with a better understanding of  
52  
53 symptoms, fewer somatic symptoms or improved physical  
54  
55 HRQoL.  
56  
57  
58  
59  
60

## EMOTION PROCESSING &amp; FUNCTIONAL SYMPTOMS

[TABLE 2]

Partial correlation coefficients were calculated to elucidate the relationship between the CORE-10 / MHS total scores and the EPS-25 total score when either CORE-10 or MHS-specific variance was controlled for. After controlling for the MHS total difference score, the correlation between the EPS-25 total difference score and the CORE-10 total difference score was smaller, and the amount of shared variance decreased, but the correlation was still statistically significant [partial correlation = .57,  $r^2 = .32$ ,  $p < .001$ , 95% CI [.23, .83]]. Similarly, when controlling for the change in MHS scores, the correlation between the EPS-25 total difference scores and the CORE-10 total difference score was reduced, and the amount of shared variance reduced, but the correlation remained significant [partial correlation = .56,  $r^2 = .31$ ,  $p < .001$ , 95% CI [.31, .84]]. These results indicate that EPS-25 change scores accounted for 45% and 40% of variance in CORE-10 and MHS change scores respectively.

**Study non-completers**

Seventy-four patients consented for the intervention did not provide complete follow-up data (Figure 1). Therefore, to examine whether attrition biased the results as far as possible, study completers were compared against study non-completers on a series of key variables. There were no associations between whether a patient completed the study and the

## EMOTION PROCESSING &amp; FUNCTIONAL SYMPTOMS

1  
2  
3 demographic variables of gender, economic activity, and FNS  
4  
5 type. However, study non-completers were younger ( $M = 34.2$   
6  
7 years,  $SD = 11.6$ ) than study completers ( $M = 41.4$  years,  $SD =$   
8  
9  $13.5$ );  $t(75) = 2.48$ ,  $p = .02$ , 95% CI [-12.96, -1.87]. Study non-  
10  
11 completers were also less likely to complete therapy (38.2%  
12  
13 completed therapy, 61.8% did not complete therapy) in the  
14  
15 judgement of the therapist;  $\chi^2(1) = 5.91$ ,  $p = .02$ . However, the  
16  
17 absence of clear differences between study completers and non-  
18  
19 completers in terms of emotion processing and other baseline  
20  
21 measures suggests that study completers were representative of  
22  
23 the total consented sample on the available psychological  
24  
25 parameters (Table 3).  
26  
27  
28

29  
30 [TABLE 3]  
31

### 32 Discussion

33  
34  
35 Abnormal emotion processing is an important target for  
36  
37 psychotherapy in patients with FNS because it may contribute  
38  
39 to FNS aetiology (Novakova et al., 2015), and appears to be  
40  
41 related to a poorer quality of life and understanding of the  
42  
43 disorder (Baker et al., 2007). Therefore, the aim of this study  
44  
45 was investigate whether emotion processing improved in  
46  
47 patients with FNS following a course of BAPIT. We also  
48  
49 explored the extent to which changes in emotion processing  
50  
51 correlated with treatment-associated changes in HRQoL and  
52  
53 other measures of clinical symptomology.  
54  
55  
56  
57  
58  
59  
60

## EMOTION PROCESSING &amp; FUNCTIONAL SYMPTOMS

1  
2  
3 As predicted, emotion processing improved post-  
4 intervention, accompanied by improved HRQoL and illness  
5 understanding. Although psychological distress and other  
6 somatic symptoms failed to improve significantly, change  
7 scores on the EPS-25 correlated positively with change scores  
8 on the CORE-10 and MHS sharing 45% and 40% of variance  
9 respectively. This suggests that improvements captured by the  
10 EPS-25 are not simply of academic interest but clinically  
11 meaningful to patients.

19  
20  
21  
22  
23

24 To our knowledge this the first study to examine  
25 therapy-associated changes in emotion processing in patients  
26 with FNS. The significant improvement in HRQoL observed in  
27 our patient group is consistent with our previous observations  
28 in this patient population (Reuber, Burness, et al., 2007).  
29 However, this time we did not observe significant  
30 improvements in somatic symptoms or psychological distress.  
31 This discrepancy could be due to the smaller sample size in the  
32 present study reducing statistical power. Illness understanding  
33 was not measured in the previous study but we did observe a  
34 significant improvement in the present patient cohort. One  
35 earlier study in a much larger sample showed that having a  
36 poor illness understanding of FNS as measured by the Illness  
37 Beliefs Questionnaire (including a non-attribution of functional  
38 symptoms to psychological factors), is a strong predictor of  
39  
40  
41  
42  
43  
44  
45

## EMOTION PROCESSING &amp; FUNCTIONAL SYMPTOMS

1  
2  
3 poor patient outcome on a 'Clinical Global Improvement Scale'  
4  
5 at twelve month follow-up (Sharpe et al., 2010).  
6  
7

8 The present pre-intervention EPS-25 scores support  
9  
10 previous observations that many patients with FNS experience  
11  
12 abnormal emotion processing. Group mean pre-intervention  
13  
14 total EPS-25 scores fell within the top 25<sup>th</sup> percentile for UK  
15  
16 normative values and well within the range for mental health  
17  
18 patients (Baker et al., 2007). When administered to patients  
19  
20 with NEAD only, Novakova et al. observed similar  
21  
22 abnormalities in emotion processing (Novakova et al., 2015).  
23  
24 Here we extend this finding to include patients with other forms  
25  
26 of FNS including functional motor and sensory symptoms.  
27  
28  
29  
30

31 The breadth of emotion processing styles assessed by  
32  
33 the EPS-25 is a strength of this study. It could be argued that  
34  
35 other forms of emotion processing measurement fail to reflect  
36  
37 the multi-faceted nature of emotion perception, regulation, and  
38  
39 expression (Baker et al., 2007). Therefore, the EPS-25 is likely  
40  
41 to be well-suited to detecting the heterogeneous abnormalities  
42  
43 of emotion processing which other studies have found to be  
44  
45 associated with FNS (Carson et al., 2012). The fact that the  
46  
47 EPS-25 was sensitive to changes in illness understanding and  
48  
49 HRQoL, corroborate the usefulness of this scale in clinical and  
50  
51 research settings of patients with FNS.  
52  
53  
54  
55

**Limitations**

## EMOTION PROCESSING &amp; FUNCTIONAL SYMPTOMS

1  
2  
3 The high attrition rate is a regrettable limitation of this  
4 study. As is often the case with postal-questionnaire designs, a  
5 significant proportion of data were lost by patients' failure to  
6 return the follow-up questionnaires. Another limitation is the  
7 lack of control group or a pre-treatment monitoring period  
8 demonstrating a lack of spontaneous improvements in emotion  
9 processing. Although spontaneous clinical improvements may  
10 be considered unlikely in view of the chronicity of the  
11 functional disorders treated in this study (mean duration of 5.8  
12 years ( $SD = 10.8$ )), these limitations introduce the possibility  
13 that any improvements in emotion processing, HRQoL, and  
14 clinical symptomology could simply reflect regression to the  
15 mean. Furthermore, mechanism or direction of therapeutic  
16 change cannot be inferred. Although we only found an age  
17 difference between the patient groups completing and not  
18 completing BAPIT, the generalizability of our study findings is  
19 diminished by the fact that older patients were more likely to  
20 complete treatment than younger ones. This age disparity in  
21 therapy completion resonates with earlier studies noting a  
22 greater probability of older patients engaging in specialist  
23 psychotherapy for FNS (Howlett, Grunewald, Khan, & Reuber,  
24 2007). In view of the lack of a control group and the relatively  
25 high attrition rates in this study, the influence of BAPIT on  
26 emotion processing requires further clarification. While the  
27 delivery of BAPIT by a single, highly-trained and experienced  
28

## EMOTION PROCESSING &amp; FUNCTIONAL SYMPTOMS

1  
2  
3 therapist (SH) means that there was a low risk of deviation  
4  
5 from the therapeutic approach (Hobson, 1985; Howlett &  
6  
7 Reuber, 2009), the absence of treatment data generated by other  
8  
9 therapists also limits the generalizability of the findings  
10  
11 presented here.  
12

13  
14  
15 The fact that not all patients who contributed follow-up  
16  
17 data had completed therapy and that these patients were  
18  
19 retained in the analysis should be considered a strength of this  
20  
21 study. The inclusion of these patients in our analysis should  
22  
23 mean that the findings of our study come closer to the sort of  
24  
25 effects on emotion processing BAPIT might achieve in real-life  
26  
27 rather than research settings.  
28  
29

30  
31 We were also able to exclude some other biases.  
32  
33 Patients with NEAD and those with other FNS were matched  
34  
35 on key demographic variables irrespective of FNS semiology,  
36  
37 minimising the risks of bias associated with analysing a small  
38  
39 and heterogeneous population as whole. Consecutive  
40  
41 recruitment of participants from two sites further reduced risk  
42  
43 of bias introduced by patient selection.  
44  
45

**Conclusions**

46  
47  
48 In this prospective, uncontrolled study of patients with  
49  
50 FNS we provide preliminary evidence that emotion processing  
51  
52 improves following a course of BAPIT, with simultaneous  
53  
54 improvements in HRQoL and illness understanding.

## EMOTION PROCESSING & FUNCTIONAL SYMPTOMS

1  
2  
3 Improvements in emotion processing correlated with a  
4  
5 reduction in psychological distress as well as an improved  
6  
7 mental HRQoL. We also conclude that the EPS-25 shows  
8  
9 promise as a tool for the investigation of emotion processing  
10  
11 deficits in patients with FNS. Future research should aim to  
12  
13 replicate these preliminary findings in controlled studies with  
14  
15 larger sample sizes.  
16  
17

### **Acknowledgements**

18  
19  
20  
21  
22 We would like to thank the patients for their participation in  
23  
24 this study. We would also like to thank Roy Indrasenan for his  
25  
26 administrative support during the study.  
27

Figure 1 – Flowchart of patient attrition

110x197mm (150 x 150 DPI)

Table 1

*Pre- and post-intervention EPS-25 total and subscale scores.*

EPS-25 scores	<u>Pre-intervention</u>		<u>Post-intervention</u>	
	<i>M</i>	<i>SD</i>	<i>M</i>	<i>SD</i>
Suppression	5.43	2.58	4.69	2.83
Unprocessed emotion	5.56	2.86	4.72	2.73
Unregulated emotion	4.40	2.34	4.10	2.38
Avoidance	5.07	2.29	4.53	2.28
Impoverished emotional experience	4.33	2.64	3.64	2.55
Total	4.96	2.26	4.33	2.31

*Note.* EPS-25 = Emotion Processing Scale-25. *N* = 44.

Table 2

*Bootstrapped Pearson's Correlations (r - values) between pre- and post-intervention questionnaire change scores.*

Measure	EPS-25	PHQ-15	CORE-10	BIPQ	MHS	PHS
EPS-25	-					
PHQ-15	.467	-				
CORE-10	.673*	.282	-			
BIPQ	.160	.199	.024	-		
MHS	.634*	.342	.331	.313	-	
PHS	.167	.461	-.122	.307	-.010	-

*Note.* \*significant at adjusted  $p$  value ( $p < .008$ ) using the Holm-Bonferroni correction. CORE-10 = Core Outcome in Routine Evaluation-10, BIPQ= Brief Illness Perceptions Questionnaire, PHQ-15= Patient Health Questionnaire- 15, MHS= SF-36 Mental Health Summary Scale, PHS= SF-36 Physical Health Summary Scale

Table 3

*Comparison of patients who completed the study and those who did not complete the study on baseline emotion processing and clinical symptomatology measures.*

Measure	<u>Completers</u>		<u>Non-completers</u>		<i>df</i>	<i>t</i>	<i>p</i>	<u>95% CI</u>	
	<i>M</i>	<i>SD</i>	<i>M</i>	<i>SD</i>				<i>LL</i>	<i>UL</i>
EPS-25	4.96	2.64	5.10	1.92	75	.18	.84	-0.76	1.04

CORE-10	19.20	9.40	19.50	10.40	75	.14	.09	-3.80	5.30
PHQ-15	12.80	5.60	14.30	4.90	45	.96	.360	-1.52	4.49
BIPQ	56.10	11.10	48.70	10.30	54	2.52	.02	-12.78	-0.074

Note. \*significant at adjusted  $p$  - value ( $p < .008$ ) using the Holm-Bonferroni correction. Completers = patients who completed the study. Non-completers = patients who did not complete the study CI = Bootstrapped confidence interval; LL = lower limit; UL = upper limit. EPS-25 = Emotion Processing Scale-25 Total Score, CORE-10 = Core Outcome in Routine Evaluation-10, BIPQ = Brief Illness Perceptions Questionnaire, PHQ-15 = Patient Health Questionnaire- 15, MHS = SF-36 Mental Health Summary Scale, PHS = SF-36 Physical Health Summary Scale.

## Supplementary Table 1

*Comparisons of demographic and therapy characteristics between patients with NEAD (n = 32) and patients with 'other FNS' (n = 12).*

Characteristics	NEAD	Other FNS	Statistic
Female (%)	77.4	76.9	$\chi^2(1) = .001, p = .979$
Mean age at start of therapy ( <i>SD</i> )	40.42 (14.55)	44.32 (10.12)	$t(42) = -.853, p = .398$
Economically active (%)	67.7	53.8	$\chi^2(1) = .764, p = .382$
Mean sessions ( <i>SD</i> )	10.90 (11.05)	14.42 (10.48)	$t(41) = -.948, p = .349$
Completed therapy (%)	56.7	69.2	$\chi^2(1) = .599, p = .439$

Note. NEAD = Nonepileptic Attack Disorder, Other FNS = hemiparesis, jerking, memory problems, dizziness. Mean sessions = number of sessions received by patients.

## Supplementary table 2

*Comparison of emotion processing and outcome measure scale scores from patients who*

Measure	<u>Completers</u>		<u>Non-completers</u>		<i>df</i>	<i>t</i>	<i>p</i>	<u>95% CI</u>	
	<i>M</i>	<i>SD</i>	<i>M</i>	<i>SD</i>				<i>LL</i>	<i>UL</i>
EPS-25	5.33	2.10	4.68	2.28	41	-.96	.36	-2.03	0.66
PHQ-15	13.75	5.35	14.63	5.52	35	.47	.64	-2.78	4.52
CORE 10	19.82	9.20	18.00	9.94	41	-.60	.54	-7.96	4.10
BIPQ	53.52	10.50	60.50	11.30	31	1.80	.08	-.38	14.26
MHS	39.72	9.94	40.72	10.70	37	.30	.80	-5.90	7.67
PHS	36.60	11.80	35.88	11.34	37	-.15	.86	-7.44	7.75

*completed therapy (completers) versus those who did not complete therapy (non-completers).*

*Note.* \*significant at adjusted *p* - value Holm-Bonferroni correction. CI = confidence interval; *LL* = lower limit; *UL* = upper limit. CORE-10 = Core Outcome in Routine Evaluation-10, BIPQ= Brief Illness Perceptions Questionnaire, PHQ-15= Patient Health Questionnaire- 15, MHS= Mental Health Summary Scale, PHS= Physical Health Summary Scale.
