Abstract

Objectives

To compare the likelihood of success at selection into specialty training for doctors who were UK nationals but obtained their primary medical qualification (PMQ) from outside the UK ('UK overseas graduates') with other graduate groups based on their nationality and where they gain their PMQ. We also compared subsequent educational performance during postgraduate training between the graduate groups.

Design

Observational study linking UK medical specialty recruitment data with postgraduate educational performance (Annual Review of Competence Progression (ARCP) ratings).

Setting

Doctors recruited into national programmes of postgraduate specialist training in the UK from 2012 to 2016.

Participants

34,755 UK based trainee doctors recruited into national specialty training programmes with at least one subsequent ARCP outcome reported during the study period, including 1,108 UK overseas graduates.

Main outcome measures

Odds of being deemed appointable at specialty selection and subsequent odds of obtaining a less versus more satisfactory category of ARCP outcome.

Results

UK overseas graduates were more likely to be deemed appointable compared to non-EU medical graduates who were not UK citizens (OR 1.29, 1.16 to 1.42), though less so than UK (OR 0.25, 0.23 to 0.27) or European graduates (OR 0.66, 0.58 to 0.75). However, UK overseas graduates were subsequently more likely to receive a less satisfactory outcome at ARCP than other graduate groups. Adjusting for age, sex, experience and the economic disparity between country of nationality and place of qualification reduced intergroup differences.

Conclusions

The failure of recruitment patterns to mirror the ARCP data raises issues regarding consistency in selection and the deaneries' subsequent annual reviews. Excessive weight is possibly given to interview performance at specialty recruitment. Regulators and selectors should continue to develop robust processes for selection and assessment of doctors in training. Further support could be considered for UK overseas graduates returning to practice in the UK.

Keywords: International medical graduates, medical regulation, medical selection

Strengths and limitations of this study

- The quantity, representativeness and completeness of the data available, consisting of 34,755 UK based trainee doctors.
- The observational nature of the study meant we could not control for the effects of unmeasured variables not captured in the dataset.
- The use of Annual Review of Competence Progression (ARCP) as an outcome allowed comparisons to be made both across and within specialties.
- Some restriction of range may be present, since ARCP outcomes were only observed for those who entered specialty training.

Introduction

The medical workforce is globalised, with international movement of doctors.(1) The UK is one of the largest net importers of doctors with around 33% of doctors registered with the medical regulator, the General Medical Council (GMC) having graduated from outside of the UK.(2) The situation is different for doctors in training, where in 2015 85% have a UK Primary Medical Qualification.(3) Some specialties in the UK are particularly dependent on doctors who obtained their primary medical qualification abroad in order to fill training posts. Such specialties include general practice and the psychiatric specialties.(4) The reliance on overseas doctors in the UK is likely to continue. Indeed, the recent pledge by the Health Secretary for England, Jeremy Hunt, to provide 1,500 extra medical school places per year, starting in 2018 will not provide additional applicants for basic speciality ('ST1 level') training programmes until 2025. This is based on a five year undergraduate medical degree and two subsequent postgraduate years of 'foundation' clinical training.(5) The effect of 'Brexit' (the

1
2
3 UK leaving the EU) is also likely to have an impact on the number of non-UK European
4 doctors working in the British National Health Service (NHS).
5

6
7 Previous research in the UK regarding international medical graduates has focussed on
8 identifying differences in performance on postgraduate exams and ARCPs when compared
9 to doctors with UK primary medical qualifications.(6-8) Such studies have identified a
10 number of demographic and educational factors associated with later postgraduate
11 academic performance. For example, international medical graduates who obtained higher
12 scores on the Professional and Linguistic Assessments Board (PLAB) exams and the
13 English fluency test (IELTS), used to obtain registration with the GMC, have educational
14 outcomes closer to UK medical graduates.(7, 9, 10)Differential attainment has also been
15 observed in postgraduate medical examinations in North America.(11) There are a variety of
16 views about the underlying reasons for these differences.(12)
17
18
19
20
21

22 Approximately 3-4% of all UK doctors in training (see results section) are UK citizens who
23 obtained their primary medical qualification outside of the UK - referred to here as 'UK
24 overseas graduates'. This includes those who obtained their medical degrees from both
25 countries within and without the European Economic Area (EEA). At present virtually nothing
26 is known about this group of doctors. However, a previous study reported some interesting
27 differences in performance on the PLAB exams between UK overseas graduates and non-
28 UK citizens who qualified outside of the EU (referred to here as 'international medical
29 graduates'). Compared to the international medical graduates, the UK overseas graduates
30 were observed, on average, to have more attempts and lower scores on part 1 of the PLAB
31 exam (the written component). In addition they had reduced performance on the knowledge-
32 based component of the Membership of the Royal College of General Practitioners exam
33 (MRCGP) relative to the international medical graduates. Interestingly no significant
34 difference in scores on the clinical component on the MRCGP was observed between the
35 two groups.(7) A North-American study reported that US citizens with non-US primary
36 medical qualifications perform less well in US medical licensing exams (USMLE) and are
37 less likely to be board certified specialists compared to other groups of doctors.(13) Of more
38 concern was the observation that the patients of doctors who are American citizens with
39 non-US primary medical qualifications had poorer clinical outcomes than those treated both
40 by non-US international and US medical graduates.(14) Thus, it is possible that differential
41 educational attainment may translate, in some cases, to poorer clinical care.

47
48
49
50
51

52 For a doctor to practise in the UK they must fulfil the requirements of the 1983 Medical Act.
53 (15) For international medical graduates this often involves evidencing their clinical
54 competence by passing both parts of the PLAB test, though other routes to registration are
55
56
57

1
2
3 available, especially for more experienced practitioners. The first part of the PLAB evaluates
4 medical knowledge using multiple choice questions. Part 2 of the PLAB is an evaluation of
5 practical clinical skills using a series of objective structured clinical examination stations. To
6 be eligible to sit the PLAB test doctors must have an acceptable medical degree. (15) Until
7 2014 for those from countries outside of the EEA, where English was not an official
8 language, evidence of English proficiency must have been provided. Since 2014 this applies
9 to all countries, including EEA countries too, that are not on the GMC's 'first and native'
10 English language list. (16) However, UK citizens who obtained their primary medical
11 qualification outside of the EEA would generally have to pass the PLAB test in order to
12 demonstrate clinical competency prior to obtaining a license to practice. Paradoxically this is
13 not the case with citizens of other EEA countries who qualified from a non-European
14 institution, as long as they have practiced medicine within the EEA for at least three years. In
15 this latter case an exemption from sitting the PLAB test may be granted to the doctor via
16 their "enforceable Community right" which is conferred via their European Union (EU)
17 citizenship. Nevertheless those seeking to register must provide robust evidence of their
18 competence, and as no entitlement to registration exists under this route, failure to do so will
19 result in refusal. This situation may change following the UK's exit from the EU.(17)

21
22
23
24
25
26
27
28
29
30
31 Obtaining a licence to practise does not guarantee employment. In particular doctors
32 registering to practise via the PLAB route will often be seeking to obtain a place on a
33 specialty training programme, which is the most usual pathway to both general practice and
34 senior hospital medical positions. In the UK these are usually divided into core training and
35 higher specialist training. It is usual for doctors to complete their core specialist training
36 before applying for a higher specialist training post, though some training programmes, such
37 as General Practice, Paediatrics and Obstetrics and Gynaecology are 'run through' and do
38 not have such a break. The time spent at each stage will vary depending on the specialism.
39 Postgraduate examinations, linked to the relevant Royal College, must be passed at varying
40 stages in order to progress and eventually obtain a certificate of completion of training
41 (CCT). This CCT permits a doctor to be placed on the GMC Specialist or GP Register. In the
42 UK recruitment into specialty training programmes is now largely organised around a
43 nationalised system, though some local 'standalone' posts may still exist, particularly if they
44 are short-term posts intended to cover unplanned vacancies (e.g. 'Locum Appointed for
45 Training Posts'- LAT). Applications to specialist training programmes use the online Oriel
46 system. Online application forms and evidence of qualifications are submitted and selectors
47 then generate short-listing scores based on the job criteria. Applicants to some core-training
48 posts and for general practice, may also have to complete additional tests such as those
49 found in the Multi-Specialty Recruitment Assessment (MSRA)(18). Applicants successful at

1
2
3 any initial stages will be invited to attend further face-to-face assessments and interviews at
4 national selection centres.(19) It is currently unknown, other than for GP selection (20),
5 whether the probability of a doctor's success at specialty recruitment predicts, as ideally it
6 should, subsequent educational performance in postgraduate medical training.
7
8
9

10 Previous research has identified a number of demographic factors that are associated with
11 performance in postgraduate medical training.(8, 21, 22) From a patient perspective the
12 causes of any disparities in performance between medical graduate groups are not likely to
13 be as important as the very fact they exist. However, attempting to control for the influence
14 of such variables in studies of inter-group differences may be useful in clarifying the
15 underlying relationships with the outcomes of interest. For instance, gender has been
16 associated with performance in postgraduate medical examinations.(21) Increasing age
17 tends to be associated inversely with performance both in postgraduate education (6, 22)
18 and practice.(23, 24) In contrast clinical experience tends to improve performance in both.(6,
19 25) However, there is something of an interaction between age and experience in that,
20 increasing age tends to offset the benefits of experience when determining clinical
21 outcomes.(23, 26)
22
23
24
25
26
27
28

29 Qualitative research findings have suggested that linguistic and cultural factors may, at least
30 partly, mediate these differential attainment rates between home and overseas medical
31 graduates.(27, 28) In UK citizens who graduate from abroad these language and cultural
32 factors may be assumed to be less prominent than in non-UK overseas graduates. However,
33 preparedness for practice has been highlighted as an issue even with UK medical
34 graduates.(29) It may be that those who experience their undergraduate training in another
35 country may be less well prepared to work in the UK Health Services.(30) This may be
36 reflected in educational performance. In particular it is possible that those training in a very
37 different socioeconomic context may be the most disadvantaged in this respect. Specifically
38 the nature of clinical practice may be shaped by the healthcare resources in a country.
39
40
41
42
43
44

45 The reasons for UK citizens applying to study medicine outside their home country are likely
46 to be varied but at present unknown. However, in the US roughly half of all Americans who
47 study medicine outside of the States previously or concurrently applied to US medical
48 schools.(31) Similarly a major motivation for UK citizens applying abroad may be that they
49 consider themselves unlikely to obtain a place to study medicine at a British university. It is
50 possible that family links, tuition costs and other sociocultural influences may encourage
51 study outside of the UK.
52
53
54
55
56
57
58
59
60

1
2
3 Data are routinely collated by the GMC on demographics and educational performance of
4 doctors registered to practise in the UK. Thus, the aims of our study were:
5

- 6 • To compare the likelihood of being deemed appointable to a national medical
7 postgraduate training programme for UK citizens who obtain their medical degrees
8 overseas, compared to other graduate groups.
9
- 10 • To evaluate whether subsequent differential attainment in postgraduate training was
11 observed for such UK citizens who graduated abroad, compared to other groups of
12 medical graduates.
13
- 14 • To compare any patterns observed, as above, in order to assess the effectiveness of
15 selection into postgraduate training, in relation to a doctor's nationality and place of
16 qualification.
17
18
19

20
21 Thus, our findings would have implications for both international medical regulators and
22 employers.
23

24 **Methods**

25
26
27 Our aim was to compare the chances of success at specialty training selection between UK
28 overseas graduates and the other graduate groups, both before and after controlling for the
29 effects of potential confounding factors, such as age, sex, and duration of UK based
30 experience. We then compared the subsequent Annual Review of Competence Progression
31 (ARCP) outcomes across groups. We then evaluated the extent to which the probability of
32 success, in relation to other medical graduate groups, at selection was mirrored by
33 subsequent ratings of performance in postgraduate training. The ARCP process involves a
34 regular review of the progress of a UK doctor in training by an educational panel. This panel
35 considers the evidence presented in the doctor's portfolio, which includes anonymised
36 cases, reflections and feedback from a supervisor, colleagues and workplace based
37 assessments. It does not usually involve a face-to-face meeting unless issues arise that
38 require clarification or a less than satisfactory outcome is likely to result.(32)
39
40
41
42
43
44
45

46 **Data sources and preparation**

47
48
49 Data on the outcomes of recruitment to specialty training for the UK between 2012 and 2016
50 were obtained via an extract from the Oriol database (33) supplied to the GMC. The
51 recruitment process was concerned with appointing doctors to training programmes at Core-
52 training (CT) and up to and including Specialty Training (ST) level 4 (i.e. to the earlier years
53 a training programme, the length of which is determined by the specialty). The flow of data
54
55
56
57

1
2
3 through the study is depicted in Figure 1. Oriel recruitment data were potentially available for
4 52, 894 doctors of whom 34, 755 were linked to the subsequent ARCP dataset (see below).
5 The two potential outcome variables available from the Oriel recruitment database were
6 '*deemed appointable*' and '*post offered*'. In order to reduce the impact of local competition on
7 the results the '*deemed appointable*' variable was used as the outcome measure for the
8 recruitment data modelling. Data were also available on interview performance and
9 shortlisting ratings, which were standardised as z scores (mean 0, sd of 1) within each year
10 and specialty. Note that in GP recruitment, an applicant can receive an offer without
11 interview if they score above a certain threshold on the Multi-Specialty Recruitment
12 Assessment.⁽¹⁸⁾ In these cases, the interview score was treated as missing. In this sample,
13 interview score was missing for 5,198 applications for GP specialty training (17.63%).
14
15

17
18
19
20
21

22 INSERT FIGURE 1 ABOUT HERE
23
24
25
26
27

28 Data relating to performance in training were potentially available for 90, 240 doctors in
29 specialist training with 344, 492 competency-based ARCP outcomes recorded (see below
30 and Figure 1), who were in national postgraduate training schemes between August 2009
31 and August 2016. We also noted that there were 838 doctors (2.4%) who only had ARCP
32 outcomes that were awarded in relation to short term 'Locum appointment for training' (LAT)
33 or 'Fixed term specialty training appointment' (FTSTA) posts. The data were analysed within
34 a 'Safe Haven' environment.⁽³⁴⁾ The ARCP data are collected annually by the GMC, the
35 collection notices are published on the GMC website.⁽³⁵⁾
36
37
38
39
40

41 Record of in-training assessment scores were recoded to the equivalent ARCP outcome
42 codes. Only ARCP 'competency-based' outcomes indicating training progress were included
43 (e.g. 'out of programme' experience was excluded). The remaining outcomes were then
44 collapsed onto a four point ordinal scale:
45
46
47

- 48 • 1='satisfactory progression'/'training programme completed' (ARCP outcomes '1' or
49 '6', respectively)
- 50 • 2='additional evidence requested' (ARCP outcome '5')
- 51 • 3='targeted training required [no extended time]' (ARCP outcome '2')
- 52 • 4='extended training time required/left programme' (ARCP outcomes '3' or '4',
53 respectively)
- 54
- 55
- 56
- 57

1
2
3 This was an approach previously shown to be valid.⁽⁶⁾ The dataset also contained a
4 variable, recorded by the deaneries, to indicate whether a specific ARCP outcome was
5 associated with a failure to pass a postgraduate examination (i.e. those required by the UK
6 Royal Colleges as part of specialist training). When ARCP outcomes were treated as
7 dichotomous we classified any outcome other than a '1' ('satisfactory progress') or a '6'
8 ('training programme completed') as "less than satisfactory". Note that this included outcome
9 '5' which the ARCP 'Gold Guide' does not classify as 'unsatisfactory'.⁽³²⁾ Training deanery,
10 specialty and medical training grade, all matched to individual ARCP records, were obtained
11 from deaneries via the GMC.
12
13
14
15

16
17 For the sample the nationality and the name and country of the medical school where the
18 primary medical qualification was obtained were derived from the GMC List of Registered
19 Medical Practitioners (LRMP). According to the GMC dual nationality was recorded in 2115
20 (2.4%) of the sample. Where dual nationality occurred only the first nationality provided by
21 the GMC was used. The country of origin was deleted by the GMC only in four instances
22 prior to release as a safeguard against identifying the individual doctors.
23
24
25

26
27 Graduate status was categorised predominantly, though not exclusively, according to GMC
28 regulatory policy; i.e. whether the doctor would have been expected to have passed the
29 PLAB test in order to provide evidence of clinical competence and obtain a licence to
30 practise. Thus, for analytic purposes the sample was grouped as follows:
31
32

- 33 1. *UK medical graduates (UKGs)* - irrespective of country of nationality.
- 34 2. *Graduates who were nationals of countries from the EEA* (with the exception of the UK),
35 irrespective of country of qualification.
- 36 3. *International medical graduates (IMGs)* who were non-EEA nationals, irrespective of
37 place of graduation (excepting the UK)
- 38 4. *UK overseas graduates (UK OGs)* - UK nationals who graduated from an institution
39 outside of the UK (either EEA or non-EEA).
40
41
42
43

44 The graduate group classification is further described in Table 1.
45
46
47
48

49 INSERT TABLE 1 ABOUT HERE
50
51
52

53 Note that in the above classification that within the group of UK overseas graduates there
54 were those that would have been likely to sit the PLAB exams (i.e. those who graduated
55
56
57

1
2
3 outside of the EEA) and those that were not (i.e. those graduating from universities within
4 the EEA). For this reason a sub-analysis of this group was conducted (see Results). It
5 should also be noted that group 2 (EEAGs) was defined by nationality rather than place of
6 qualification. This was because citizens of the EEA do not tend to obtain a license via the
7 PLAB route if they have worked clinically in a European country for three years or more. In
8 our sample 155 out of 1225 EEA nationals (12.65%) had obtained their primary medical
9 qualification from outwith the EEA.
10
11
12

13
14 Dichotomised ethnicity data (White/Non-white) was available from the GMC annual national
15 training survey.⁽³⁶⁾ However, ethnicity was used for descriptive purposes only and not
16 utilised in the modelling. This was because ethnic status served as a proxy for graduate
17 group membership (e.g. only 15% of the UK overseas graduates reported themselves as of
18 White ethnicity). Thus, ethnicity was, in effect, confounded by graduate group allocation.
19
20 Sex, year of birth and date of first UK medical registration was also obtained from the list of
21 registered medical practitioners. For the recruitment data analyses the duration of
22 experience in UK medical practice was calculated from the years of birth and application. For
23 analyses relating to ARCP, the duration of experience in UK medical practice was calculated
24 from the year of birth and date of ARCP.
25
26
27
28

29
30 Specialties were classified predominantly according to the Royal College they were affiliated
31 to, as in our previous study.⁽⁶⁾ We wished to understand whether training in a relatively less
32 well-resourced undergraduate medical environment mattered or whether the degree of
33 dissonance between the country of nationality and country of qualification was relevant.
34
35 Consequently we derived a metric of the economic status of the country of nationality and
36 qualification, and the difference between these two for each doctor. This was done by linking
37 the gross domestic product (GDP) per capita in US dollars, according to the 2008 World
38 Bank data ⁽³⁷⁾ to the name of the associated countries in the sample. The discrepancy
39 between these values was also calculated as both a relative and absolute difference.
40
41
42
43

44 **Patient and public involvement**

45
46 Patients were not involved in this study.
47

48 **Analyses**

49
50 For the recruitment outcomes multi-level logistic regressions were used to estimate
51 predictive models for the binary outcomes. Application events were treated as repeat
52 measurements nested within doctors, with the intercept of the model allowed to vary
53 randomly across each applicant.
54
55
56
57

1
2
3 Likewise ARCPs were treated as repeat measurements nested within doctors. Thus,
4 multilevel ordinal logistic regression analyses were used to estimate the odds of obtaining a
5 less versus a more satisfactory ARCP outcome. The intercept of the model was allowed to
6 vary randomly across each doctor in training. No clustering effects (as indicated by the
7 intraclass correlation) for deanery were observed and thus no control for this was required.
8
9 For the prediction of subsequent training performance analyses were conducted both with
10 and without ARCP outcomes associated with postgraduate exam failure. This was in order to
11 evaluate the impact of the examination performance on the ARCP outcomes in each
12 graduate group and across the main medical specialties.
13
14
15

16
17 For both sets of analyses the baseline category of graduate group was swapped to evaluate
18 all combinations of comparison. As part of the modelling process all combinations of
19 interactions between the predictor variables were evaluated. Only interaction terms that were
20 statistically significant (at the $p < 0.05$ level) and substantively meaningful were included in
21 the final models. Multivariable model building proceeded in a forward stepwise manner with
22 a p value of < 0.05 from univariable analysis being the criterion for entry. The predictor
23 variables used in the multivariable model building, including the available potentially
24 confounding variables, were: age, UK experience, ethnicity, sex, selection standardised
25 shortlisting scores and standardised interview scores.
26
27
28
29
30

31 Analyses by specialty group were conducted and the results from three of these reported as
32 exemplars: *general practice*, *psychiatry* and *surgery*. General practice and psychiatry were
33 selected as they had relatively high proportions of UK overseas graduates working in them.
34 Moreover, relatively high differential performance at both ARCP and postgraduate
35 membership exams between UK and international graduates have been reported.⁽⁶⁻⁸⁾ The
36 results for the surgical specialties are also presented as, traditionally, entry to the training
37 schemes are more competitive than most other medical fields.⁽³⁸⁾
38
39
40
41

42 Missing data were relatively uncommon (see Figure 1), other than for shortlisting score and
43 interview score. As such, we repeated the above analyses using multiply imputed data
44 using chained equations, creating 20 imputed dataset, as implemented in STATA 14. This
45 portion of the analysis can be thought of as a sensitivity analyses for these two selection
46 variables. Specifically, if the results between the imputed and non-imputed datasets vary
47 then this would be evidence that the absent values are 'missing not at random' (i.e. the
48 missing values are neither associated with the observed data nor due to chance). Thus, the
49 results in relation to any affected variables must be interpreted more cautiously.

Results

Descriptive statistics

As can be seen from Figure 1, there were relatively few missing data in the final sample of doctors. For example, country of nationality and/or qualification was unavailable in only 301 (0.8%) of the doctors in this final sample. The exceptions to this are the shortlisting score, which was missing in 45.9% of cases, and interview score, unavailable for 30.2% of the final sample.

Table 2 shows the demographic characteristics of the doctors in the final sample (where both recruitment and ARCP outcomes were available) in relation to the recruitment outcomes. As can be seen from Table 2, UK overseas graduates were more likely than UK graduates to be male and report non-White ethnicity. It can also be seen that, on average, UK overseas graduates had slightly lower standardised short-listing scores but somewhat higher mean interview scores than non-UK international medical graduates. UK overseas graduates were, on average, approximately five years older than UK graduates at specialty application with around a year of extra UK clinical experience at the time of the first recorded ARCP. It can also be seen from Table 2 that, on average, international medical graduates applied for more specialty posts than UK overseas graduates during the study period, though were less often deemed appointable by the selection panel. The background characteristics and overall ARCP outcomes for the four groups of medical graduates are shown in Table 3. As can be seen, compared to other graduate groups, UK overseas graduates were more likely to receive a 'less than satisfactory' outcome at ARCP which was more likely to be associated with a failure to pass a postgraduate exam.

INSERT TABLE 2 ABOUT HERE

INSERT TABLE 3 ABOUT HERE

Table 4 depicts a breakdown of the composition of doctors in training in each specialty according to graduate group. Overall 1108 (3.19%) of the doctors in our sample were UK overseas graduates. As can be seen, those disciplines where competition for training places

1
2
3 is less competitive (38) tend to have the highest proportion of UK overseas graduates, such
4 as psychiatry (145/2183, 6.6%).

Modelling outcomes from specialty selection

The results from the univariable analyses are depicted in Table 5 and Figure 2. In order to further reduce the impact of competition effects (i.e. less highly achieving candidates applying for the least competitive specialties) we also repeated the specialty-based analyses with the three exemplars (*psychiatry, surgery and general practice*). Results by specialty are shown in Figure 3. As can be seen from the results in the left hand column of Table 5 and also Figure 2, UK overseas graduates were less likely than UK graduates or EEA nationals to be deemed appointable at specialty selection. However, they were more likely than international medical graduates who were not UK nationals to be deemed appointable (OR 1.29, 1.16 to 1.42). Also apparent in Table 5 is that females, younger and more experienced doctors were more likely to be successful at recruitment. Those who were nationals or qualified from wealthier countries were more also more likely to be deemed appointable. Disparities between a country of qualification and nationality's income, in either direction, were associated with a reduced odds of being deemed appointable, with the odds being roughly reduced by 25% for every difference of \$10,000 per capita.

INSERT TABLE 5 ABOUT HERE

INSERT FIGURE 2 ABOUT HERE

INSERT FIGURE 3 ABOUT HERE

The results from the multivariable analyses, predicting outcome at specialty recruitment are also contained in Table 5, in the right-hand column. Results adjusted for various predictor variables are also shown in Figure 2. One interaction term that was statistically significant at

1
2
3 the $p < 0.05$ level and conceptually justifiable was included in the modelling. This was the
4 term representing the interaction between age and experience. This term, when
5 exponentiated as an odds ratio, was less than one. This highlights that the advantage of
6 increasing experience at interview was offset by more advanced age. The pattern in the
7 multivariable results observed was generally similar to the univariable results. As can also be
8 seen from Figure 2, as expected, progressively controlling for background variables,
9 shortlisting scores and interview performance reduces the disparities in odds of being
10 deemed appointable between the UK medical graduates and non-UK graduate groups.
11 However, it is notable from the results shown in Table 4 that the difference in the odds
12 between a UK overseas graduate and a non-UK international medical graduate increased
13 after controlling for other predictor variables. Another noteworthy observation is that once the
14 odds are conditioned on the relative interview scores the shortlisting scores become non-
15 significant to the probability of being deemed appointable.
16

21
22

23 **Modelling ARCP outcomes**

24
25
26 In total there were data relating to 99,293 ARCP outcomes relating to 34,755 doctors in
27 specialist training in the final dataset. As can be seen from the flow of data depicted in
28 Figure 1 there were relatively few missing data. Statistical significance, in the present case,
29 should be assumed to be at the $p < 0.001$ level, unless otherwise stated.
30
31
32

33 In terms of univariable analyses, graduate group was associated with an increased odds of
34 receiving a less satisfactory ARCP outcome at review, with UK overseas graduates showing
35 the largest difference with UK medical graduates as the comparison category (Figure 4).
36 This pattern was replicated across the three specialties selected as exemplars (Figure 5).
37 We also noted no significant difference in the odds of a less satisfactory ARCP outcome
38 between UK overseas graduates who are generally expected to sit the PLAB test ($n=812$)
39 and those who had qualified from a medical school within the EEA ($n=793$, OR 1.16, 0.91 to
40 1.47, $p=0.24$); the latter sub-group ($n=294$) being exempt from the test.
41
42
43
44
45

46 Both increasing age and UK experience at ARCP were associated with higher odds of a less
47 satisfactory outcome, as was male sex. In the case of age and experience, the odds of a
48 poorer versus better outcome increased by approximately 5% per year. Likewise, the odds
49 of males having a less, rather than more, satisfactory outcomes, were about 43% higher
50 than those for females doctors (Table 6).
51
52
53

54 Both the GDP of the country of nationality and that of the place of qualification had roughly
55 equal influences on ARCP outcomes: for every \$10 000 extra per capita the GDP of the
56
57

1
2
3 country the odds of a less satisfactory (versus more satisfactory) outcome dropped by
4 approximately 20%. However, the most potent predictor in this regard was the absolute
5 difference in GDP between country of nationality and place of qualification. This indicated
6 that the odds of a less satisfactory (versus more satisfactory) outcome increased by
7 approximately 22% for every \$10 000 per capita difference between the two countries,
8 regardless of the direction of the disparity.
9

10
11
12 Once ARCP outcomes associated with postgraduate exam failure were excluded from the
13 analyses the effect sizes of the predictors diminished to varying degrees though remained
14 statistically significant in all cases (Table 6 - right hand column and Figure 4). This indicated
15 that some of the association between ARCP outcomes and graduate status and the other
16 predictors were mediated by differential Royal College exam pass rates.
17
18

19
20
21 The influence of background variables was controlled for in the multivariable analyses. We
22 observed that the differences in ARCP outcomes between the UK medical graduates and
23 those who held non-UK primary medical qualifications diminished to some extent (Figure 4).
24 Moreover when the impact of differential postgraduate exam pass rates were also adjusted
25 for (by excluding the relevant ARCP outcomes) the inter-group differences further reduced,
26 disappearing entirely for UK overseas graduates versus home medical graduates. We also
27 noted that (in contrast to the univariable results), once the influence of age was controlled
28 for, UK-based experience predicted the probability of more, rather than less, satisfactory
29 ARCP outcomes. The results are also depicted in Table 7.
30
31
32
33

34
35 The picture when analyses were conducted for each specialty group was similar (Figure 5).
36 As can be seen, even after adjusting only for the influence of background variables there
37 were no differences remaining in the odds of a more satisfactory ARCP outcome between
38 UK overseas and home graduates in the surgical trainees. Likewise, no statistically
39 significant differences remained after excluding ARCPs associated with exam failure in
40 psychiatry and general practice (Figure 5). It is worth noting that all the other predictors in
41 the model, including an interaction term for age and experience remained statistically
42 significant and independent predictors of ARCP outcome (Table 7).

11 **Results from the imputed datasets**

12
13 When re-running the multivariable analysis predicting 'appointability' at specialty recruitment
14 on the imputed data, unlike the analysis on the non-imputed dataset (Table 5), both
15 shortlisting score (OR 1.05, 1.03 to 1.08) and interview score (OR 3.13, 3.03 to 3.23) are
16 significant independent predictors.
17
18

19
20 In contrast, the analyses for ARCP outcome show negligible difference whether being
21 performed on the non-imputed data or the imputed data.
22
23
24
25

26 **Discussion**

27
28 In this study, the first to focus on UK overseas graduates, we observed that this group of
29 doctors were more likely to be deemed appointable at specialty training recruitment than
30 non-UK international medical graduates, though less so than other graduate groups. Marked
31 disparities in ARCP outcomes between this group of doctors and other graduate types were
32 also noted. The patterns observed in the selection data were not precisely replicated, with a
33 're-ordering' of UK and non-UK overseas medical graduates. In the present case the
34 dissonance between the selection and ARCP results could be largely, if not wholly,
35 explained by the differential interview performances between UK and non-UK international
36 medical graduates. This finding is consistent with a previous report into selection and
37 subsequent educational achievement in those recruited to UK general practice training-
38 performance on selection measures were noted to be less strongly predictive of subsequent
39 scores at the MRCGP exam in international, compared to home graduates.(20)
40
41
42
43
44
45

46 The magnitude of intergroup differences in ARCP outcomes reduced after controlling for the
47 influence of age, UK experience and absolute economic differences between the country of
48 nationality and qualification. We also observed a significant interaction between age and
49 (UK-based) clinical experience, in line with previous findings.(23) In addition the inter-group
50 differences further diminished after excluding ARCP outcomes associated with exam failure,
51 and indeed vanished for UK overseas graduates versus home graduates following these
52 adjustments. This pattern was generally seen across the medical specialties.

Comparison with other studies and possible interpretations

Our observation that the disparities in the odds of entering specialist training in the UK recruitment data were not precisely mirrored by ARCP outcomes was consistent with data from North America on selection to medical specialties. US international medical graduates tend to have higher odds of being placed in a residency programme than their non-US counterpart (39) despite subsequent reduced specialty certification rates for North American citizens who trained outside of the country.(40)

Likewise our findings in relation to postgraduate educational performance were in keeping with those from previous studies of postgraduate education performance in international medical graduates training in the UK.(10) Specifically our observations concurred with those reported by McManus and Wakeford who reported lower scores on the PLAB part 1 (written component) and Applied Knowledge Test (AKT) of the MRCGP exam.(7) However, in the latter study only a subset of UK international medical graduates (i.e. those who registered via the PLAB system) were included. We noted that the magnitude of inter-group differences was less marked in the more competitive disciplines. Over time, increasing competition ratios may drive up educational performance and so reduce any disparities between medical graduate groups.

By comparing the raw and adjusted odds ratios we obtain some indications of factors that may underlie the observed differences in ARCP outcomes. Certainly age, UK experience and the interaction between these two variables play a role. Moreover, it appeared that it was the absolute, rather than relative difference, between the economic status of country of nationality and qualification which had the larger influence on ARCP outcomes. This observation leads to the inference that there was something different about those individuals who studied medicine in a setting economically, and probably culturally different to their home country. It is also interesting to observe that controlling for the influence of the background predictors and postgraduate exam pass rates reduced the difference in ARCP outcomes between UK overseas and home graduates to a somewhat greater degree than those between the latter group and non-UK international medical graduates (see Fig. 4). It is thus likely that some of the remaining, unexplained gap in ARCP performance between these latter two groups is accounted for by, perhaps subtle, linguistic and sociocultural factors, previously referred to as the 'dark variance' of differential attainment.(41)

1
2
3 It also seemed that many of the 'less than satisfactory' ARCP outcomes (as defined by the
4 authors) were disproportionately associated with exam failure in UK international medical
5 graduates. Thus, removing these reviews from the analyses diminished the observed inter-
6 group differences. This raises questions about both the reliability of each assessment, as
7 well as the constructs that they purport to measure. At present the reliability of the ARCP is
8 unknown, though the process has recently been subject to a qualitative review.(42) In
9 contrast there is some existing evidence of acceptable reliability for the Royal College
10 postgraduate examinations.(43, 44) Moreover, where psychometrically investigated, no
11 evidence of racial bias was detected (45) though, at least for the MRCGP CSA, more subtle
12 sociocultural forms of bias cannot be ruled out.(8, 27) It could also be assumed that ARCP
13 panels consider a range of factors in addition to clinical knowledge and skills, though do not
14 usually involve a face-to-face interview.(32) These attributes may include perceived
15 professionalism, ability to team work and administrative efficiency. Regarding the contrast
16 between ARCP and the recruitment into specialty training results- it could be argued that the
17 latter process gives some additional scope for bias (both conscious and unconscious). For
18 example, there is evidence that face-to-face interviewers sometimes base decisions on
19 misleading cues.(46) Although there are structured elements to the selection process it can
20 be assumed that 'softer' abilities, such as presentational skills will partly determine the
21 outcome.(47) Thus, non-UK candidates, and especially those for whom English is not their
22 first language, may be disproportionately disadvantaged, compared to the ARCP process.
23 This possibility is supported by our observation that UK overseas graduates received, on
24 average, higher interview scores at selection than non-UK international medical graduates. It
25 was noteworthy that once performance at interview was controlled for in the modelling the
26 graduate groups restacked into an order that was more consistent with that observed for
27 ARCP performance. This raises the issue about whether excessive weight is given to
28 interview performance within the specialty selection process. Such 'overweighting' might
29 lead to situations where a candidate destined for satisfactory performance in postgraduate
30 training is passed over in favour of one who outperforms them at interview but is less likely
31 to make satisfactory future progress. It should be recognised that both in the UK and
32 elsewhere postgraduate medical selectors are working to increase the standardisation and
33 structure of their processes.(48) In particular, the introduction of Situational Judgement Tests
34 (SJTs) as a component of selection into UK general practice training may effectively
35 evaluate some of the non-academic qualities of candidates.(49) Such assessments are
36 usually used at an early stage screening processes which leaves scope for candidates to
37 diverge in performance at later stages of selection. Thus these observations raise the
38 question of whether ARCP and selection processes should become more like the
39 postgraduate exams or vice versa? Perhaps ideally postgraduate examinations should test a

1
2
3 wider range of qualities important to real world practice, including the ability to demonstrate
4 culturally-appropriate professionalism and team-working. Likewise the ARCP process has
5 been recently qualitatively reviewed⁴¹ and at the time of writing there are plans to review it in
6 order to improve its reliability, acceptability and validity.(50)
7
8

9 **Strengths and potential limitations**

10
11 The primary strength of this study is the quantity, representativeness and completeness of
12 the data available. This leads to the power to detect inter-group differences, even in sub-
13 group analyses. The use of ARCP as an outcome allowed comparisons to be made both
14 across and within specialties. We were also able to adjust for the impact of differential pass
15 rates at postgraduate exams. Unlike in some previous studies, country of both nationality
16 and place of qualification were available, allowing a more granular analysis, including by
17 GDP. However, it should be noted that we only had access to the nationality of the doctor at
18 the point of registration with the GMC. Thus, we were unable to differentiate between
19 doctors who were designated UK citizens at birth and those who obtained this status
20 subsequently.
21
22

23
24 The major limitation in this case was the observational nature of the study. Thus, we could
25 not control for the effects of unmeasured variables not captured in the dataset. Nevertheless,
26 by controlling for the effects of the predictor variables we had access to, as well as by
27 excluding ARCPs associated with postgraduate exam failure, we were able to obliterate the
28 observed differences in overall performance between the UK overseas and home graduates.
29 Naturally these results do not give rise to causal explanations for the differences. However,
30 they do guide the focus of further investigation into the factors underlying these disparities,
31 for example, differential pass rates at the Royal College membership examinations. We also
32 noted a small percentage (2.4%) of doctors who only had ARCP outcomes recorded in
33 relation to short-term training posts (e.g. LATs). The posts held by this small group of
34 doctors may have not been typical of training posts in general. However, when we excluded
35 these medical trainees from the analyses no meaningful impact on the results was noted.
36 Moreover, in practice, such short-term training appointments are sometimes awarded to
37 doctors who then subsequently obtain a place on a substantive training programme. Thus, it
38 did not appear practicable to differentiate between such temporary posts and longer term
39 training programmes in the analyses.
40
41

42
43 It should be noted that, in this study, ARCP outcome '5' ('further information required') was
44 used as an intermediate outcome category when conducting our modelling. In practice a
45 request for further information may, occasionally, be due to the failure of a supervisor, or
46
47
48
49
50
51

1
2
3 other third-party, to supply documentation and may be due to the actions of the trainee
4 themselves. However, in line with our previous findings and exploration of the use of ARCP's
5 as an educational outcome, it was felt that use of the 'outcome 5' in this way was justified.
6
7 (6)
8

9
10 When comparing the results from the analysis of ARCP outcomes to the recruitment
11 processes it must be borne in mind that some level of 'filtration' has already occurred by the
12 time doctors enter postgraduate training. That is to say that the range of the data has been
13 restricted in that ARCP outcomes were only observed for those doctors successfully entering
14 specialty training. Thus, the degree of disparity between the different graduate groups may
15 have been underestimated. In particular those who obtained their primary medical
16 qualification outside of the UK may be especially likely to be in non-training medical posts
17 and not included in the present sample. Moreover, at least for the more competitive
18 specialties, in accordance with EU employment law, those who were not nationals from the
19 European Economic Area may not have been shortlisted if there were deemed sufficient
20 numbers of applicants from Europe. In addition we only had access to date of registration
21 with the GMC and could not estimate years of practice outside of the UK. However, it may
22 be that practice in a comparable healthcare setting may be more important in predicting
23 educational and clinical performance than experience *per se*. A further limitation was that
24 ARCP were not directly linked to the programmes interviewed for. This was because the
25 structure of the data were complicated and the doctors sometimes changed speciality, or
26 were undergoing 'dual' training in more than one speciality.
27
28
29
30
31
32
33
34

35
36 Some caution must be exercised when interpreting the interview scores as predictors of
37 recruitment outcomes. The decision to deem a candidate 'appointable' is almost wholly
38 based, at that stage of selection, on the interview ratings, and thus there is a tautological
39 element to this aspect of the analysis Nevertheless it was informative to compare the
40 standardised interview scores between the graduate groups. This permitted us to identify the
41 source of the advantage that the UK overseas graduates had over the non-UK citizens who
42 had graduated from outside of the EEA at selection.
43
44
45

46
47 Both shortlisting score and interview score displayed extensive missingness, and the analysis
48 relating to selection into specialty training on the imputed dataset produced somewhat
49 differing results than those for the non-imputed data. The reduction in odds ratio observed
50 for the interview score in the imputed data set is not an unexpected result – only an
51 application which proceeded to interview will have an associated interview score. Thus,
52 there is likely to be some 'restriction of range' present. The shortlisting score was missing in
53 nearly half of all cases, and the change in significance for shortlisting score in the
54
55
56
57

1
2
3 multivariable model suggest that these data were not missing at random. It is possible that
4 the missing data was at least partly due to differences in deanery returning practices. As the
5 imputed analysis displayed somewhat different results, some caution must be exercised
6 when interpreting the results specifically relating to appointability at specialty recruitment and
7 the shortlisting scores.
8
9

10
11 These findings raise important questions that could be answered by both further quantitative
12 and qualitative studies. If the data could be made available further research could be
13 conducted to understand the differences in royal college examination performance across
14 the four graduate groups that the ARCP results presented here suggest exist. The reasons
15 why UK citizens study abroad may be varied; ideally one could identify whether the such
16 individuals had applied to medical school in the UK unsuccessfully or attended a UK medical
17 school but left at some point. For these cases, it may be possible to obtain data from their
18 application to UK medical school in the UK, for example aptitude test scores, as a measure
19 of their educational performance prior to completing their degree.
20
21
22
23
24

25 **Conclusions**

26
27 We observed a significant effect for NHS experience. This implies that in order to enhance
28 the postgraduate educational performance of doctors who graduate from overseas additional
29 training opportunities could be effective. In particular, previous research has highlighted the
30 challenges that overseas doctors experience when transitioning to the UK NHS. It may be
31 that UK citizens who have undergone their undergraduate training in other settings are not
32 readily identified as potentially benefitting from additional support. This would be because
33 culturally and linguistically they would not be expected to stand out from home medical
34 graduates and less likely to experience cultural dissonance. As such policy could highlight
35 this group as one that could be targeted for additional support with transitioning. Additionally,
36 not all doctors entering UK training from overseas have completed their foundation training,
37 these doctors require a supervisor (sometimes from abroad) to verify that they have
38 achieved foundation competencies (the Alternative Certificate of Foundation Competence).
39 At present it is unclear what proportion of non-UK graduates this relates to and whether they
40 are disadvantaged in any way.
41
42
43
44
45
46
47
48

49 While conducting this study we noted some inconsistencies in the current UK regulatory
50 policy. For example, European citizens who study outside of the EEA are not expected to sit
51 the PLAB (if having practised in the EEA for at least three years) whilst UK citizens in a
52 similar situation generally would undergo the assessments. In addition, those UK overseas
53 graduates who would usually be expected to demonstrate their competency via the PLAB
54
55
56
57

1
2
3 system did not have significantly better ARCP outcomes than those who did not. Most PLAB
4 candidates eventually pass both parts so the impact of the exam on future ARCP
5 performance in this subgroup may not be substantial.(51) However, previous research has
6 shown that PLAB scores do predict both ARCP and postgraduate exam performance in
7 international medical graduates.(6, 7) Once the UK leaves the EU there is a potential
8 opportunity for changes to medical regulation. For example, 'Brexit' could potentially allow
9 for the introduction of a national licensing exam that will be taken by all doctors wishing to
10 practice in the UK regardless of nationality or place of qualification, subject to any
11 exemptions that are agreed. The GMC has been consulting on plans to introduce such a test
12 in the form of the UK 'Medical Licensing Assessment'.(52) It is important to point out that in
13 other parts of the world the introduction of such licensing exams do not, in themselves,
14 ensure equivalence in subsequent performance between differing medical graduate groups.
15 (11) Nevertheless it would hopefully help ensure minimum standards of competence and a
16 greater degree of fairness in the regulatory system.
17
18
19
20
21
22
23

24 Those UK nationals who choose to study medicine abroad before returning to the NHS are
25 unlikely to be a homogenous group. Thus further research should focus on understanding
26 the qualitative characteristics of this category of doctor. Importantly we do not know whether,
27 as in the US, this group of nationals who qualified overseas have inferior patient outcomes
28 compared to other categories of medical practitioner.(14) Certainly the observations alluded
29 to by McManus and Wakeford (7), that UK overseas graduates performed more poorly on
30 the knowledge but not the clinical component of the MRCGP, are intriguing. Indeed they may
31 imply, at least for UK overseas graduates who sit the PLAB, that it may be mainly
32 performance on knowledge, rather than skills-based assessments that are at least driving
33 the differential attainment between this latter and other medical graduate groups. Thus, for
34 these reasons research examining actual UK-based clinical practice into differing graduate
35 groups is urgently required.
36
37
38
39
40
41
42

43 The present study, in the context of previous work in this area, suggests that the regulations
44 governing the right to practise medicine in a particular country should not be determined by
45 either nationality or place of qualification. Rather they should be based on a reliable and
46 equitable evaluation of clinical ability and other personal qualities essential to the practice of
47 medicine in that specific national context. The introduction of a licensing exam into the UK
48 would provide an opportunity to implement such policy. The impact of such a licensing exam
49 should be carefully evaluated as at present it is unclear whether such a universal
50 assessment is likely to translate into improved safety and quality of patient care.(53)

13
14

15 **Declarations**

16
17 **Ethical approval:** Not required. The study relied on the analysis of de-identified routinely
18 collected data analysed within a 'safe haven' environment. This was confirmed in writing by
19 the chair of the University of York Department of Health Sciences Ethics Committee.
20
21

22
23 **Consent for publication:** Not applicable.
24
25

26 **Data sharing statement:** The data and associated STATA syntax used to manage and
27 analyse the data are archived and may be made available from the GMC on request within a
28 safe haven environment on an individual basis should a sufficient justification be provided.
29 No additional individual data available.
30
31

32 **Competing interests:** The time that DS spent working on this project was funded as part of
33 his role at the General Medical Council (GMC). However, the views expressed in this article
34 do not necessarily reflect those of the GMC. PAT has previously received research funding,
35 via a competitive tendering processes, as lead and co-applicant from the GMC, Health
36 Education England and the Department of Health for England.
37
38
39
40

41 **Funding:** PAT is supported in his research by the National Institute for Healthcare Research
42 (NIHR) via a Career Development Fellowship. This paper represents independent research
43 part-funded by the National Institute for Health Research (NIHR). The views expressed are
44 those of the authors and not necessarily those of the NHS, the NIHR or the Department of
45 Health. The time that DS spent working on this project was funded as part of his role at the
46 General Medical Council (GMC). However, the views expressed in this article do not
47 necessarily reflect those of the GMC.
48
49
50
51

52 **Authors' contributions:** PAT led on conception, design, statistical analysis and
53 interpretation of data and is the guarantor of the paper. JO contributed to the cleaning,
54 management and analysis of the data and drafting the article. LWP conducted analyses and
55
56
57

1
2
3 produced the data visualisations of the results as well as contributing to drafting and critically
4 appraising the article. DS was involved in cleaning and managing the data as well as
5 drafting, revising the article and critically appraising the content. JJN was involved in
6 providing supervision and advice in relation to the analyses as well as contributing to drafting
7 and critically appraising the article. All authors (PAT, JO, LWP, DS and JJN) have approved
8 the final version of the article submitted.
9
10
11

12 **Acknowledgements:** The authors are grateful to GMC colleagues who commented on the
13 paper: Richard Amison, Ben Griffith, Neil Jinks, Andy Knapton, Nicola While and Kirsty
14 White. The views expressed are those of the authors and not the GMC.

Tables

Group name	Region where PMQ obtained	Nationality
UK medical graduates (UKGs)	UK	All
EEA graduates (EEAGs)	EEA	All – except for UK nationals
International Medical Graduates (IMGs)	Outside of EEA and UK	All – except for UK nationals
UK overseas graduates (UK OGs)	Outside of UK (EEA or non-EEA country)	UK national

Table 1. Classification of medical graduate groups for purposes of study.

Group	Male (%)	Non-white ethnicity (%)	Mean shortlisting z score (sd)	Mean interview z score (sd)	Mean no. of jobs applied to during the study period (SD)	Mean no. deemed appointable (sd)	Mean no. offered (sd)
1. UKGs	12008/28293 (42%)	9235/28249 (33%)	0.31 (0.84)	0.27 (0.91)	1.97 (1.41)	1.36 (0.87)	1.25 (0.74)
2. EEAGs	535/1225 (44%)	191/1209 (16%)	-0.17 (1.06)	-0.24 (0.93)	2.49 (2.13)	1.17 (1.00)	0.96 (0.80)
3. IMGs	2120/3828 (55%)	3597/3766 (96%)	-0.46 (0.91)	-0.45 (0.90)	3.08 (2.66)	1.01 (0.98)	0.80 (0.73)
4. UK OGs	652/1108 (59%)	925/1093 (85%)	-0.45 (0.90)	-0.42 (0.92)	2.94 (2.49)	1.11 (0.91)	0.92 (0.71)

Table 2. Background and specialty recruitment characteristics of the doctors in the sample by graduate group. Recruitment data values for the study period August 2009-2016.

Group	Mean age at 1 st ARCP (SD)	Mean UK experience at 1 st ARCP (SD)	Mean number of ARCPs (SD)	Proportion 'unsatisfactory' (i.e. not outcome 1 or 6)	Proportion of ARCPs associated with postgraduate exam failure (%)
1. UKGs	29.00 (3.31)	2.62 (1.30)	3.29 (2.04)	19511/80361 (24.28%)	3213/80361 (4.00%)
2. EEAGs	31.85 (4.55)	3.54 (2.06)	3.22 (2.04)	1093/3341 (32.71%)	347/3341 (10.39%)
3. IMGs	34.68 (4.66)	4.14 (2.08)	3.70 (2.38)	3902/11404 (34.22%)	1086/11404 (9.52%)
4. UK OGs	34.38 (5.60)	3.82 (2.10)	3.49 (2.15)	1167/3174 (36.77%)	348/3174 (10.96%)

Table 3. Summary of the background and Annual Review of Competence Progression (ARCP) descriptive statistics for the doctors in the study sample.

Specialty group	UK medical graduates (%)	EEA nationals (%)	IMGs (%)	UK overseas graduates (%)
Anaesthetics	2918 (91.53%)	61 (1.91%)	149 (4.67%)	37 (1.16%)
Medicine	6329 (79.18%)	336 (4.20%)	1040 (13.01%)	233 (2.92%)
Psychiatry	1289 (61.82%)	143 (6.86%)	489 (23.45%)	136 (6.52%)
Surgery	3394 (82.82%)	173 (4.22%)	357 (8.71%)	131 (3.20%)
EM and ACCS	1070 (80.21%)	47 (3.52%)	162 (12.14%)	46 (3.45%)
GP	9353 (83.45%)	219 (1.95%)	1126 (10.05%)	409 (3.65%)
Obs & Gynae	822 (78.36%)	51 (4.86%)	132 (12.58%)	36 (3.43%)
Occ Medicine	6 (50.00%)	1 (8.33%)	3 (25.00%)	0 (0.00%)
Ophthalmology	341 (82.37%)	26 (6.28%)	29 (7.00%)	10 (2.42%)
Paediatrics	1557 (81.82%)	105 (5.52%)	192 (10.09%)	37 (1.94%)
Lab based	309 (75.55%)	23 (5.62%)	64 (15.65%)	11 (2.69%)
Public Health	123 (91.79%)	3 (2.24%)	1 (0.75%)	1 (0.75%)
Radiology	688 (83.29%)	36 (4.36%)	78 (9.44%)	20 (2.42%)
All specialties	28199(81.41%)	1224 (3.52%)	3822 (11.01%)	1108 (3.19%)

Table 4. Number of doctors in the sample (percentage of total) in specialty training by graduate group and specialty

Predictor	Univariable Models	Multivariable Model
	Odds Ratio (95% CI)	Odds Ratio (95% CI)
UK overseas graduates vs UKG	0.25 (0.23 to 0.27)	0.65 (0.56 to 0.77)
UK overseas graduates vs EEAG	0.66 (0.58 to 0.75)	0.65 (0.53 to 0.81)
UK overseas graduates vs IMG	1.29 (1.16 to 1.42)	1.05 (0.89 to 1.23)*
Male sex	0.70 (0.68 to 0.73)	-
Shortlisting score (z score)	1.74 (1.69 to 1.80)	-
Interview score (z score)	8.41 (8.10 to 8.73)	6.78 (6.47 to 7.10)
Age at selection	0.93 (0.93 to 0.94)	-
UK experience (years) at selection	1.50 (1.47 to 1.52)	1.17 (1.08 to 1.27)
Experience/age interaction	-	0.99 (0.99 to <1.00)†
GDP of Country of nationality (\$10k per person)	1.52 (1.50 to 1.55)	-
GDP of Country of qualification (\$10k per person)	1.63 (1.60 to 1.65)	-
Difference in GDP countries (\$10k per person)	0.87 (0.85 to 0.89)	-
Absolute difference in GDP (\$10k per person)	0.74 (0.73 to 0.76)	-

Table 5. Results from univariable and multivariable multi-level logistic regressions predicting the odds of being deemed appointable at specialty training recruitment.

* p>0.5

† p=0.01

Predictor	Including exam failures	Excluding exam failures
	Odds Ratio (95% CI)	Odds Ratio (95% CI)
UK overseas graduates vs UKG	2.36 (2.12 to 2.62)	1.77 (1.59 to 1.96)
UK overseas graduates vs EEAG	1.29 (1.12 to 1.48)	1.30 (1.13 to 1.50)
UK overseas graduates vs IMG	1.20 (1.07 to 1.35)	1.14 (1.02 to 1.28) [‡]
Male sex	1.43 (1.38 to 1.49)	1.37 (1.32 to 1.43)
Age at ARCP	1.05 (1.05 to 1.05)	1.03 (1.03 to 1.04)
UK experience (years) at ARCP	1.04 (1.03 to 1.05)	1.02 (1.02 to 1.03)
GDP of Country of nationality (\$10k per person)	0.83 (0.82 to 0.84)	0.88 (0.87 to 0.90)
GDP of Country of qualification (\$10k per person)	0.80 (0.79 to 0.82)	0.87 (0.85 to 0.88)
Difference in GDP countries (\$10k per person)	1.06 (1.03 to 1.09)	1.03 (>1.00 to 1.05) [§]
Absolute difference in GDP (\$10k per person)	1.22 (1.19 to 1.25)	1.15 (1.12 to 1.18)
Mean shortlisting score (z score)	0.63 (0.61 to 0.64)	0.76 (0.74 to 0.78)
Mean interview score (z score)	0.61 (0.59 to 0.62)	0.71 (0.69 to 0.72)

Table 6. Results from a series of univariable multilevel ordinal logistic regression analyses predicting the odds of 'less' vs 'more' satisfactory ARCP outcomes for the sample of doctors (N=34,755). In the right hand column the results from analyses where ARCP outcomes associated with postgraduate exam failure were excluded are shown.

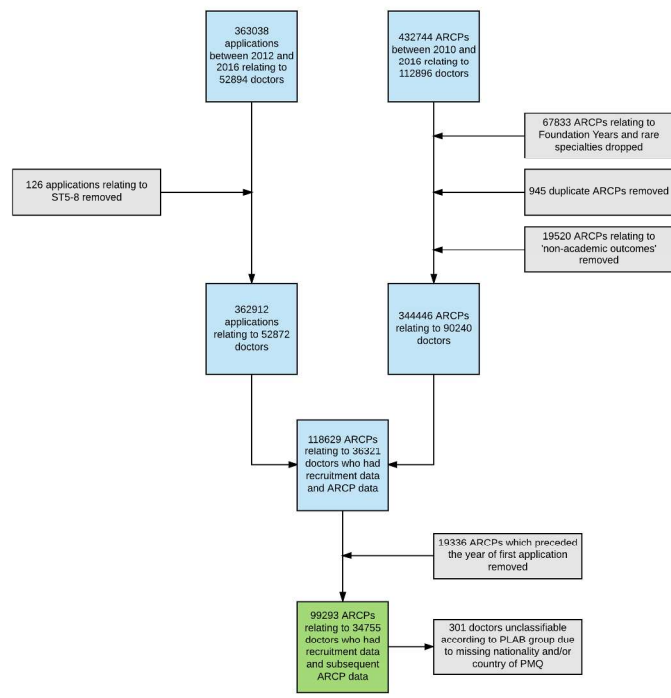

[‡] p=0.02
[§] p=0.04

Predictor	Including exam failures	Excluding exam failures
	Odds Ratio (95% CI)	Odds Ratio (95% CI)
UK overseas graduates vs UKG	1.08 (0.92 to 1.26)**	1.05 (0.90 to 1.22) [!]
UK overseas graduates vs EEAG	0.96 (0.79 to 1.16) [!]	1.04 (0.86 to 1.26) [!]
UK overseas graduates vs IMG	1.03 (0.88 to 1.21) [!]	1.03 (0.88 to 1.21) [!]
Male sex	1.28 (1.22 to 1.34)	1.29 (1.23 to 1.35)
Age at ARCP	1.02 (1.01 to 1.03) ^{††}	>1.00 (0.99 to 1.01) [!]
UK experience (years) at ARCP	0.84 (0.79 to 0.90)	0.83 (0.78 to 0.88)
Age/Experience interaction	>1.00 (>1.00 to 1.01)	>1.00 (>1.00 to >1.00)
Absolute difference in GDP (\$10k per person)	1.06 (1.02 to 1.10) ^{††}	1.05 (1.01 to 1.09)
Mean shortlisting score (z score)	0.72 (0.69 to 0.74)	0.84 (0.81 to 0.86)
Mean interview score (z score)	0.67 (0.65 to 0.69)	0.74 (0.72 to 0.77)

Table 7. Results from two multivariable multilevel ordinal logistic regression analyses predicting the odds of 'less' vs 'more' satisfactory ARCP outcomes for the sample of doctors (N=34,755). In the right hand column the results from analyses where ARCP outcomes associated with postgraduate exam failure were excluded are shown.

Section/Topic	Item #	Recommendation	Reported on page #
Title and abstract	1	(a) Indicate the study's design with a commonly used term in the title or the abstract	Page 1
		(b) Provide in the abstract an informative and balanced summary of what was done and what was found	Pages 2-3
Introduction			
Background/rationale	2	Explain the scientific background and rationale for the investigation being reported	Pages 3-7
Objectives	3	State specific objectives, including any prespecified hypotheses	Page 7
Methods			
Study design	4	Present key elements of study design early in the paper	Page 7
Setting	5	Describe the setting, locations, and relevant dates, including periods of recruitment, exposure, follow-up, and data collection	Pages 7-8
Participants	6	(a) Give the eligibility criteria, and the sources and methods of selection of participants	Pages 7-10
Variables	7	Clearly define all outcomes, exposures, predictors, potential confounders, and effect modifiers. Give diagnostic criteria, if applicable	Pages 7-10
Data sources/ measurement	8*	For each variable of interest, give sources of data and details of methods of assessment (measurement). Describe comparability of assessment methods if there is more than one group	Pages 7-10
Bias	9	Describe any efforts to address potential sources of bias	Page 10
Study size	10	Explain how the study size was arrived at	Pages 7-8 and Figure 1
Quantitative variables	11	Explain how quantitative variables were handled in the analyses. If applicable, describe which groupings were chosen and why	Pages 8-10 and Table 1
Statistical methods	12	(a) Describe all statistical methods, including those used to control for confounding	Pages 10-11
		(b) Describe any methods used to examine subgroups and interactions	Pages 10-11
		(c) Explain how missing data were addressed	Page 11
		(d) If applicable, describe analytical methods taking account of sampling strategy	N/A
		(e) Describe any sensitivity analyses	N/A

Results			
Participants	13*	(a) Report numbers of individuals at each stage of study—eg numbers potentially eligible, examined for eligibility, confirmed eligible, included in the study, completing follow-up, and analysed	Figure 1
		(b) Give reasons for non-participation at each stage	Figure 1
		(c) Consider use of a flow diagram	Figure 1
Descriptive data	14*	(a) Give characteristics of study participants (eg demographic, clinical, social) and information on exposures and potential confounders	Tables 2-4
		(b) Indicate number of participants with missing data for each variable of interest	Figure 1
Outcome data	15*	Report numbers of outcome events or summary measures	Tables 2-3
Main results	16	(a) Give unadjusted estimates and, if applicable, confounder-adjusted estimates and their precision (eg, 95% confidence interval). Make clear which confounders were adjusted for and why they were included	Tables 5-7 and Figures 2-5
		(b) Report category boundaries when continuous variables were categorized	N/A
		(c) If relevant, consider translating estimates of relative risk into absolute risk for a meaningful time period	N/A
Other analyses	17	Report other analyses done—eg analyses of subgroups and interactions, and sensitivity analyses	Page 13
Discussion			
Key results	18	Summarise key results with reference to study objectives	Pages 15-16
Limitations	19	Discuss limitations of the study, taking into account sources of potential bias or imprecision. Discuss both direction and magnitude of any potential bias	Pages 18-19
Interpretation	20	Give a cautious overall interpretation of results considering objectives, limitations, multiplicity of analyses, results from similar studies, and other relevant evidence	Pages 19-21
Generalisability	21	Discuss the generalisability (external validity) of the study results	Pages 17-18, pages 20-21
Other information			
Funding	22	Give the source of funding and the role of the funders for the present study and, if applicable, for the original study on which the present article is based	Page 22

*Give information separately for cases and controls in case-control studies and, if applicable, for exposed and unexposed groups in cohort and cross-sectional studies.

Note: An Explanation and Elaboration article discusses each checklist item and gives methodological background and published examples of transparent reporting. The STROBE checklist is best used in conjunction with this article (freely available on the Web sites of PLoS Medicine at <http://www.plosmedicine.org/>, Annals of Internal Medicine at <http://www.annals.org/>, and Epidemiology at <http://www.epidem.com/>). Information on the STROBE Initiative is available at www.strobe-statement.org.
