Notes: Columns (1) and (3) report the democratisation years of our sample according to Cheibub et al. (2010) and Boix et al. (2013) classifications, respectively, whereas columns (2) and (4) the reversals to dictatorship. In cases that countries democratise or reverse to dictatorial rule, but the sample does not cover the period before the regime change, the years are not reported in the Table. Columns (5) and (6) report by country the minimum and maximum values, respectively, of the variable *POLITY2* for the years covered in the empirical analysis - higher values indicate more authoritarianism. Finally, columns (7) and (8) indicate the Soviet and Soviet satellite countries and Sub-Saharan Africa countries, respectively, which are dropped from the estimates in Subsection 2.4.1 of the paper.

## Appendix C. A theoretical framework along the lines of McGuire and Olson (1996)

We develop a simple theoretical model that builds upon Olson (1993; 2000) and McGuire and Olson (1996). More precisely, we consider an endogenous growth model where the ruler (whether democratically elected or not) determines the level of the income tax rate and the amount of tax revenues directed to public production services. Tax revenues that are not directed to public production services remain in the discretion of the ruler to be used for his own purposes. These resources can affect the welfare of the ruler either directly by increasing his own consumption, or indirectly by increasing his ability to “buy” political support through targeted transfers to politically influential groups of agents. In both cases, this share of tax revenues is directed away from productive activities.

### B.1 Households

The intertemporal utility of the representative household is:

$$U = \sum_{t=0}^{\infty} \beta^t (\log c_t) \quad (1)$$

where  $c_t$  is the private consumption at time  $t$ , and  $0 < \beta < 1$  is the discount rate.

At each time  $t$ , the household rents its predetermined capital,  $k_t$ , to the firm and receives  $r_t k_t$ , where  $r_t$  is the return to capital. It also supplies inelastically one unit of labor services per time-period so that labor income is  $w_t$ . Further, it receives firms' profits,  $\pi_t$ . Thus, the household's budget constraint is:

$$k_{t+1} + c_t = (1 - \theta_t)(r_t k_t + w_t + \pi_t) \quad (2)$$

where  $k_{t+1}$  is the end-of-period capital stock, and  $0 < \theta_t < 1$  is the income tax rate. For simplicity, we assume full capital depreciation. The initial capital stock,  $k_0$ , is given.

The household chooses the paths of  $c_t$  and  $k_{t+1}$  to maximize its intertemporal utility subject to the budget constraint. In doing so, it acts competitively by taking prices, profits and policy variables as given. The first-order conditions of the household's problem are:

$$\frac{1}{c_t} = \beta \left[ \frac{(1 - \theta_{t+1})r_{t+1}}{c_{t+1}} \right] \quad (3)$$

and the budget constraint in (2).

### B.2 Firms

The representative firm maximizes the usual profit,  $\pi_t$ , function:

$$\pi_t \equiv y_t - r_t k_t - w_t l_t \quad (4)$$

As in the literature introduced by Barro (1990), we assume that public services provide production externalities to private firms. We also assume that technology at the firm's level takes a Cobb-Douglas form. Thus, the firm's production function is:

$$y_t = A k_t^\alpha l_t^{1-\alpha} G_t^{1-\alpha} \quad (5)$$

where  $y_t$ ,  $l_t$ , and  $g_t$  denote output, labor and public production services, respectively, at time  $t$ . Also,  $A > 0$  and  $0 < \alpha < 1$ .

The firm chooses  $k_t$  and  $l_t$ . In doing so, it acts competitively by taking prices and policy variables as given. The first-order conditions of the firm's problem are:

$$r_t = \frac{\alpha y_t}{k_t} \quad (6a)$$

$$w_t = \frac{(1 - \alpha) y_t}{l_t} \quad (6b)$$

### B.3 Government budget constraint

To finance the public good the ruler taxes the household's income at a rate  $0 < \theta_t < 1$ . Thus,

$$R_t + G_t = \theta_t (r_t k_t + w_t + \pi_t) \quad (7a)$$

Without loss of generality, we assume that a share  $0 < b_t < 1$  of total tax revenues finances public production services,  $G_t$ , and the rest  $0 < (1 - b_t) < 1$  is used by the ruler for his own purposes. These resources can finance either the ruler's own consumption or other non-productive activities. Thus, (7a) is decomposed into:

$$G_t = b_t \theta_t (r_t k_t + w_t + \pi_t) \quad (7b)$$

$$R_t = (1 - b_t) \theta_t (r_t k_t + w_t + \pi_t) \quad (7c)$$

where inspection of (7a)-(7c) reveals that  $\theta_t$  and  $b_t$  can summarize fiscal policy at time  $t$ .

#### *B.4 Competitive decentralized equilibrium (for given economic policy)*

Given the paths of the policy instruments  $\{\theta_t, b_t\}_{t=0}^{\infty}$ , a Competitive Decentralized Equilibrium (CDE) is defined to be a sequence of allocations  $\{y_t, c_t, k_{t+1}, G_t, R_t\}_{t=0}^{\infty}$  and prices  $\{r_t, w_t\}_{t=0}^{\infty}$  such that: (i) households maximize utility and firms maximize profits by taking prices, policy and public services as given; (ii) all budget constraints are satisfied; (iii) all markets clear.<sup>1</sup> This CDE is summarized by the following equations that give the paths of output, private consumption, private capital accumulation:

$$y_t = A^{\frac{1}{\alpha}} (b_t \theta_t)^{\frac{1-\alpha}{\alpha}} k_t \quad (8a)$$

$$c_t = (1 - \alpha\beta) A^{\frac{1}{\alpha}} (1 - \theta_t) (b_t \theta_t)^{\frac{1-\alpha}{\alpha}} k_t \quad (8b)$$

$$k_{t+1} = \alpha\beta A^{\frac{1}{\alpha}} (1 - \theta_t) (b_t \theta_t)^{\frac{1-\alpha}{\alpha}} k_t \quad (8c)$$

$$G_t = b_t \theta_t A^{\frac{1}{\alpha}} (b_t \theta_t)^{\frac{1-\alpha}{\alpha}} k_t \quad (8d)$$

$$R_t = (1 - b_t) \theta_t A^{\frac{1}{\alpha}} (b_t \theta_t)^{\frac{1-\alpha}{\alpha}} k_t \quad (8e)$$

---

<sup>1</sup> In the labor market, the market-clearing condition is  $l_t = 1$ .

In this solution,  $y_t$ ,  $c_t$ ,  $k_{t+1}$ ,  $G_t$  and  $R_t$  depend on the beginning-of-period capital stock and the current value of the policy instruments.<sup>2</sup>

### *B.5 Optimal fiscal policy*

We now endogenize policy by assuming that the ruler chooses the paths of  $\theta_t$  and  $b_t$  in order to maximize his own well-being (see Equation (9) below). In doing so the ruler takes into account the CDE as summarized by Equations (8a)-(8e).

#### *The ruler's problem*

Following McGuire and Olson (1996) we assume that the ruler (whether democratically elected or not) maximizes the following intertemporal objective function:

$$W = \sum_{t=0}^{\infty} \beta^t (F \log c_t + (1-F) \log R_t) \quad (9)$$

where  $0 < \beta < 1$  is the discount rate of the ruler, and  $0 < F < 1$  is a parameter that captures the degree of the encompassing interest of the ruler in the private consumption of citizens, and consequently in the productivity of the whole economy. The second term of the objective function captures the incentive of the ruler to extract the maximum amount of resources from the public funds and to be used for his own purposes. As can be easily verified, when parameter  $F$  tends to zero the ruler gains utility solely through rent extraction (this is the case of “pure autocracy”). In contrast, when  $F$  is larger than zero, the ruler also cares for the welfare of the citizens -who earn a significant share of the market income of the economy - and this inevitably lead him to care about the performance of the private market (this is the case of the “redistributive democracy”)<sup>3</sup>. We will use dynamic programming to solve the ruler's problem. From the governor's point of view, the state at any time  $t$  is the predetermined economy-wide capital stock,  $k_t$ . Then  $V(k_t)$  denote the value function at time  $t$ . This function must satisfy the Bellman equation:

---

<sup>2</sup>As is known, the model specification (logarithmic preferences and Cobb-Douglas constraints with full depreciation) allows us to obtain a closed-form solution at the level of CDE. In this equilibrium, private consumption-saving decisions are proportional to current output, and the degree of proportionality depends on the current policy instruments only.

<sup>3</sup>Though essentially ad hoc, this characterization of policy-makers' preferences is a convenient way of encompassing a wide range of possibilities by supposing that policy makers are neither wholly benevolent nor wholly self-serving Leviathan (see, e.g., Edwards and Keen, 1996 for more details on this).

$$V(k_t) = \max_{\theta_t, b_t} [F \log c_t + (1-F) \log R_t + \beta V(k_{t+1})] \quad (10)$$

where  $c_t$ ,  $k_{t+1}$  and  $R_t$  follows (8b), (8c) and (8e) respectively.

Inspection of the above problem reveals that the value function in (10) is expected to be of the log-linear form  $V(k_t) = u_0 + u_1 \log k_t$ , where  $u_0$  and  $u_1$  are undetermined coefficients. Using this conjecture for the value function into (10), the first order conditions for  $\theta_t$  and  $b_t$  are respectively:<sup>4</sup>

$$\theta_t = 1 - a\beta - a(1-\beta)F \quad (11a)$$

$$b_t = \frac{1-a}{1-a\beta - a(1-\beta)F} \quad (11b)$$

As can be easily verified, the chosen policy instruments are independent of the state of the economy  $k_t$  and they are constant over time  $\theta_t = \theta$  and  $b_t = b$  for all  $t$ . Moreover, we note that  $\frac{\partial \theta}{\partial F} < 0$  and  $\frac{\partial b}{\partial F} > 0$ . Thus, a higher encompassing interest of the ruler in private consumption, and consequently in the productivity of the private markets, leads: (i) to lower level of tax rates and (ii) to higher share of tax revenues directed to finance public production services relative to rents' extraction. It is worth noting that a higher tax rate do not necessarily induce higher tax revenues. This is because in this model national income (i.e., the tax base) is endogenous to the implemented fiscal policy. These theoretical results are in line to those obtained by McGuire and Olson (1996): rulers that are characterized by a higher (lower) encompassing interest in the welfare of the majority direct a larger (lower) share of the tax revenues to public production services, and they impose lower (higher) tax rates.

---

<sup>4</sup> Using the conjecture  $V(k_t) = u_0 + u_1 \log k_t$  into (10) and equating coefficients on both sides of the Bellman, we get  $u_1 = 1/(1-\beta) > 0$ . Plugging this into the first order conditions for  $\theta_t$  and  $b_t$  we obtain (11a) and (11b). This also confirms the conjecture for the value function in (10).
