45

46

47

48 *To the Editor:* Randomized controlled trials have shown that the phosphodiesterase-4
49 inhibitor Apremilast is an effective and safe option in the treatment of psoriasis and
50 psoriatic arthritis (PsA) (1) with real-world data now emerging from the dermatology and
51 rheumatology settings (2-5). The Canadian multicenter retrospective study showed no
52 increased reported AEs when Apremilast was used in monotherapy (MT) or in combination
53 therapy (CT) with systemic drugs in patients with plaque psoriasis and that the CT group did
54 not have superior efficacy, likely reflecting more resistant disease (2). Such data is still
55 sparse from the real-world experience in PsA patients.

56 In the first real-life report of Apremilast 30mg BD in active PsA, data were retrospectively
57 reviewed in seventy-one patients with active PsA at the tertiary Leeds Psoriatic Service (4).
58 Herein we report a sub-analysis of the safety and response to therapy data according to the
59 treatment regimen. The proportions and means were compared using Fisher's exact test and
60 two-tailed unpaired-t-test respectively. Statistical analysis was performed with GraphPad
61 Prism 7 with $p \leq 0.05$ considered significant.

62 Clinical characteristics and AEs are reported in table 1 and table 2 respectively. Of 71 PsA
63 patients, 39 (54.9%) were on MT, 32 (45.1%) on CT (Table 1). Sub-analysis of the two groups
64 showed no increased number of the reported AEs when Apremilast was used in MT or in CT
65 with conventional and/or biological disease modifying antirheumatic drugs (DMARDs) (table
66 2), confirming Ighani et al. results (2). We did not perform a statistical analysis due to the
67 small number of AEs. Unlike RCTs (1) and the retrospective study of Ighani et al (2),
68 unwanted weight loss and upper respiratory tract infections were not reported in our
69 experience (table 2) (4). Of the 51 patients with a mean follow-up ≥ 6 months, in which we
70 could assess the response to therapy (4), 28 were on MT and 23 were taking Apremilast in
71 combination with conventional (n=16) or biologic (n=5) DMARDs, or with both (n=2).

72 According to the response criteria (4), a slightly greater proportion of MT patients achieved
73 response (18/28 vs 13/23, 64.3% vs 56.5%), with not significant difference. As in the plaque
74 psoriasis real-world experience (2), this may be explained by more difficult-to-treat PsA
75 cases requiring additional drugs in order to control disease activity. When comparing
76 number of previous DMARDs and disease duration, there was no difference between MT
77 and CT groups ($p>0.05$).

78 In conclusion, the favourable safety profile of Apremilast either in MT or CT makes it highly
79 desirable in some clinical scenarios. While MT could serve to control chronically active
80 disease not responsive to previous conventional/biologic DMARDs or to treat earlier on
81 patients with less severe joint/skin manifestations who may not yet require a biologic
82 DMARD (4), the CT may reduce disease activity not adequately controlled with other
83 treatments without increasing risk of AEs. In clinical practice use of CT, particularly with
84 biologics, is currently limited by costs. Larger observational data are needed to define cases
85 who may benefit of MT and/or CT and characterise specific AEs .
