23 **Abstract**

24 A novel ratiometric fluorescence sensor based on fluorescence resonance energy
25 transfer (FRET) between MoS₂ QDs and AuNCs was developed for nitrite detection in
26 sausages. The MoS₂ QDs-AuNCs nanocomposite exhibited dual emission peaks at 430
27 nm and 615 nm under 365 nm excitation. With addition of nitrite, the fluorescence of
28 AuNCs was quenched due to the agglomeration of AuNCs, whereas the emission of
29 MoS₂ QDs increased for the blocked FRET. With this strategy, nitrite was detected in
30 the range of 0.5 – 20 mg/L with a detection limit of 0.67 nM. Furthermore, based on the
31 fluorescence color change of the sensor at different nitrite concentration, a microfluidic
32 chip combined with smartphone was developed for the fluorescent visual detection of
33 nitrite over a range of 1.0 – 20 mg/L. Finally, the developed methods were applied to
34 the determination of nitrite in sausage samples with the satisfactory recoveries of
35 102.6%-110.8%, indicating the potential for practical application.

37 visualization

38

39 **1 Introduction**

40 Chinese sausage is a popular meat product in China due to its specific flavors and
41 taste. Nitrite, as a permitted food additive, is often used in sausage for inhibiting the
42 growth of microorganisms and improving the color and flavor (Iacumin, et al., 2019).
43 However, excessive presence of nitrite will cause serious health hazard to the public
44 such as methemoglobinemia, occasional intoxications and potential cancer (Ding, Gao,
45 & Li, 2018; Viboonratanasri, Pabchanda, & Prompinit, 2018). Therefore, rapid and
46 accurate detection of nitrite content in sausage is of great importance for food safety
47 control and regulation.

48 Conventional detection methods for nitrite including high-performance liquid
49 chromatography (H. Li, Meininger, & Wu, 2000), spectroscopy (Zheng, Liang, Li,
50 Zhang, & Qiu, 2016), chromatography (Niedzielski, Kurzyca, & Siepak, 2006),
51 capillary electrophoresis (Ruri Kikurahanajiri, And, & §, 2002) and electrochemical
52 methods (Wan, Zheng, Wan, Yin, & Song, 2017). Although these techniques are stable
53 and reliable, most of them require expensive instrumentation and complicated
54 operations (Gu, et al., 2016). In comparison, fluorescence analysis may be an ideal
55 selection for nitrite detection owing to its easy operation, high sensitivity and low-cost
56 (Hu, Shi, Shi, Zou, Arslan, et al., 2019; Y. Xu, et al., 2015).

57 Fluorescence probes for nitrite detection have been reported previously (Hu, Shi,
58 Shi, Zou, Tahir, et al., 2019; Qi, You, & Chen, 2016; Q. Wang, et al., 2016). For instance,
59 A 2-(1H-phenanthro[9、10-d]imidazol-2-yl)aniline (PA) fluorescence probe was
60 developed for nitrite detection in sausage based on a novel NO₂⁻-mediated diazotation
61 and subsequent cyclization (Gu, et al., 2016). Wang et al. (Q. Wang, et al., 2016) used
62 the reaction of nitric oxide with a dihydropyridine derivative to form a highly
63 fluorescent pyridine derivative achieving ultralow detection limit of 0.02 μmol/L.
64 However, most of the above fluorescence probes used a single fluorescence peak as
65 response signal, which may be susceptible to the probe concentration, fluctuation of
66 excitation intensity and environmental interference (Santoro, et al., 2016). By contrast,
67 ratiometric fluorescence (RF) probes, based on the ratio of the dual fluorescence peaks,

68 could greatly reduce interference and improve the sensitivity for target analytes (Kaur,
69 et al., 2018). Fluorescence resonance energy transfer (FRET) has been the most
70 commonly applied mechanism for RF probe development due to the superiority of
71 design flexibility and reduction of auto-fluorescence (Xue, Wang, Ouyang, & Qiu,
72 2019). Various FRET-based RF probes have been employed for analyte sensing such as
73 hypochlorous acid (Shen, et al., 2018), cysteine (Yu, et al., 2018) and protein (H. Li,
74 Zhao, Chen, & Xu, 2017), which indicates FRET-based RF probes have great
75 application prospects. However, to our knowledge, there are few reports on nitrite
76 detection based on this strategy.

77 Previous study suggested that Molybdenum disulfide quantum dots (MoS₂ QDs)
78 strongly emit in blue wavelength under UV excitation owing to the transition from the
79 K point of Brillouin zone (Ha, Han, Choi, Park, & Seo, 2014), which makes MoS₂ QDs
80 an ideal donor for FRET. Besides, gold nanoclusters (AuNCs) have great potential for
81 the construction of dual-emission nanocomposites owing to their strong fluorescence
82 intensity, large Stokes-shift and biocompatibility (X. Yang, et al., 2016). Therefore, it
83 might be a promising method to develop a RF probe for nitrite detection by combining
84 MoS₂ QDs and AuNCs. Moreover, Microfluidic analysis system, as a powerful
85 analytical tool, have been widely used for nitrite detection (Ortiz-Gomez, et al., 2016)
86 (Bhakta, Borba, Taba, Garcia, & Carrilho, 2014) (Beaton, et al., 2011). Combining
87 microfluidic chip with MoS₂ QDs-AuNCs fluorescence probe might greatly improve
88 the detection performance for nitrite.

89 Herein, a novel FRET-based RF sensor and a fluorescence colorimetric
90 microfluidic chip were developed for the nitrite detection. Under 365 nm excitation, the
91 emission of BSA–AuNCs could be quenched by nitrite, resulting in the fluorescence
92 recovery of MoS₂ QDs. According to the phenomenon, nitrite was quantified based on
93 the ratio of fluorescence intensities at two wavelengths, and the detection mechanisms
94 were discussed in detail. Furthermore, according to the changes of fluorescence color
95 with the increase of nitrite concentration, a microfluidic chip combined with a smart
96 phone was designed and used to achieve the fluorescence visual detection of nitrite.

97 Finally, the proposed fluorescence and visualization methods were successfully applied
98 to nitrite detection in sausage.

99 **2 Materials and methods**

100 **2.1 Reagents and apparatus**

101 Glutathione (GSH), Sodium molybdate ($\text{Na}_2\text{MoO}_4 \cdot 2\text{H}_2\text{O}$), 1-ethyl-3-(3-
102 (dimethylamino)propyl)-carbodiimide (EDC) and N-hydroxy-sulfosuccinimide (NHS)
103 were obtained from Sigma-Aldrich (Shanghai, China). The remaining reagents (e.g.,
104 $\text{HAuCl}_4 \cdot 4\text{H}_2\text{O}$, bovine serum albumin (BSA) and sodium nitrite) were purchased from
105 Sinopharm Chemical Reagent Co., Ltd (Shanghai, China). All the reagents used were
106 of analytical grade. Deionized water ($18 \text{ M}\Omega/\text{cm}$) was used in all experiments.

107 The fluorescence was measured using F98 fluorescence spectrometer (Lengguang
108 technology, Shanghai, China). The morphology and structure of MoS_2 -AuNCs were
109 characterized using JEM-2000 high resolution transmission electron microscopy
110 (HRTEM) (JEOL, Tokyo, Japan). The UV–vis absorption spectra were recorded on a
111 UV-1601 spectrometer (Beifen-Ruili, Beijing, China). FT-IR spectra were performed
112 on a Nicolet IS50 FT-IR spectrometer (Thermo Scientific, Massachusetts, USA). The
113 X-ray diffraction (XRD) spectrum were obtained from a D8 Advance diffractometer
114 (Bruker, Karlsruhe, Germany). The fluorescent lifetime spectrum was measured by
115 QuantaMaster™ 40 Fluorescence Lifetime Spectrometers (PTI, USA).

116 **2.2 Synthesis and preparation of materials**

117 **2.2.1 Synthesis of MoS_2 QDs**

118 The MoS_2 QDs were synthesized through a hydrothermal method (Swaminathan
119 & Balasubramanian, 2018). Briefly, 0.25 g $\text{Na}_2\text{MoO}_4 \cdot 2\text{H}_2\text{O}$ was dissolved in 20 mL of
120 deionized water followed by sonication for 10 min. Then the solution was adjusted to
121 pH 6.5 by 0.1 M of HCl. 0.5 g of GSH was subsequently added to the solution and
122 sonicated for 10 min again. The resulting mixture was transferred to Teflon-lined
123 stainless steel autoclave and reacted at 200°C for 24 h. Finally, when the solution
124 cooled naturally, the supernatant was collected after centrifugation at 12000 rpm for

125 30 min.

126 **2.2.2 Preparation of AuNCs**

127 The BSA-stabilized AuNCs were prepared according to the reported methods (Xu,
128 Qiao, Li, Qi, & Zhang, 2015) with some modification. 5.0 mL of BSA solution (50.0
129 mg/mL) was mixed with 5.0 mL of HAuCl₄ solution (10.0 mM) under magnetic stirring
130 for 2 min. Then 0.5 mL of NaOH solution (1.0 mM) was added to adjust to pH 12. After
131 that, the mixture was sonicated for 4 h at room temperature. The resultant brown AuNCs
132 was purified via dialysis membrane (1000 Da) and stored at 4 °C for further use.

133 **2.2.3 Preparation of MoS₂ QDs-AuNCs nanohybrid.**

134 The MoS₂ QDs-AuNCs nanohybrid was prepared via coupling reaction using
135 EDC/NHS technique (Niu, et al., 2016). Specifically, 500 μL of EDC/NHS aqueous
136 solution (10 mg/mL for each) was added to 6 mL of AuNCs solution followed by
137 stirring for 30 min at 4 °C to activate the carboxyl group. Then 10 mL of prepared MoS₂
138 QDs solution was added and the mixture was incubated under vigorous stirring for 12
139 h.

140 **2.3 Ratiometric fluorescence detection of nitrite**

141 Firstly, 1.0 mL of MoS₂ QDs-AuNCs solution was mixed with different amount of
142 NaNO₂ followed by dilution to 5 mL with PBS solution. The final concentration of
143 NaNO₂ were 0, 0.1, 0.5, 1, 2, 5, 8, 10, 15, 20, 25, 30, 40 and 50 mg/L, respectively.
144 Then the mixture was incubated for 7 min under ambient temperature. The fluorescence
145 spectrum of MoS₂ QDs-AuNCs nanohybrid was recorded upon excitation at 365 nm.
146 All measurements were performed three times at room temperature.

147 **2.4 Fluorescence visualization analysis for nitrite**

148 A quantitative model was established on the dependence of fluorescence color on
149 nitrite concentrations. Firstly, Fluorescence color of the MoS₂ QDs-AuNCs system was
150 collected employing the microfluidic chips and image acquisition device (seen in the
151 supplementary materials), and the results showed fluorescence color of the probe
152 changed from red to blue with increase in nitrite concentration. Then the images
153 obtained were processed through OpenCV image library based on Android platform.

154 Specifically, background region and reaction cell were firstly segmented with the
155 powerful function of OpenCV. Because the single channel color information in RGB
156 mode can not accurately describe fluorescence color change of the system, the
157 segmented RGB images were then transformed into L*a*b model images. Next, the
158 channel “a” images were separated from L*a*b images, and average “a” values were
159 calculated according to gray information of the pixels. Finally, Standard curve was
160 established on the dependence of “a” values on nitrite concentrations.

161 **2.5 Nitrite detection in sausage samples**

162 Firstly, sausage samples (Shuanghui food Co., Luohe, China) were purchased from
163 nearby supermarket. Then they were pretreated according to the reported literature (B.-
164 L. Li, Li, & Gao, 2019). Finally, nitrite contents in the sausages were determined based
165 on the methods described in “Ratiometric fluorescence detection of nitrite” and
166 “Fluorescence visualization analysis for nitrite”.

167 **3 Results and discussion**

168 **3.1 Characterizations of prepared materials**

169 The morphology and dimensions of prepared materials were investigated by
170 HRTEM. Fig.1 A displays the TEM images of as-synthesized MoS₂ QDs. It can be
171 found the compounds are uniformly dispersed with the size ranging from 4 to 8 nm.
172 The lattice of 0.21 nm shown in the inset corresponds to the Mo (110), which is
173 consistent with previous report (Duan, et al., 2018). Fig.1 B illustrates that the particle
174 size distribution of BSA-AuNCs ranges from 3 to 5 nm with the lattice of 0.25 nm (Sun,
175 Yang, Zhao, & Yang, 2014). Compared with the single MoS₂ QDs or AuNCs, MoS₂
176 QDs-AuNCs composite shown in Fig.1 C has larger size, and the different lattice
177 spacing indicates the successful preparation of the MoS₂ QDs-AuNCs composite.

Fig.1

178
179 The crystal structures of MoS₂ QDs-AuNCs composite were further explored by
180 X-ray diffraction (XRD). As shown in Fig.1 D, the diffraction peaks at $2\theta = 14^\circ, 33^\circ,$

181 40° and 59° are ascribed separately to the (002), (100), (103) and (110) planes of
182 hexagonal phase MoS₂ while the peaks at higher 2θ angles are indexed to the (111),
183 (200), (220), and (311) planes of face-centered cubic Au (J. Yang, Elim, Zhang, Lee, &
184 Ji, 2006; Ze, Yueqiu, Xujun, & Yong, 2017). The results indicate that the MoS₂ QDs-
185 AuNCs composite has signals of both MoS₂ QDs and AuNCs.

186 The surface composition of the obtained MoS₂ QDs-AuNCs composite was
187 investigated by FT-IR spectra. As shown in Fig.1 E, AuNCs have the characteristic
188 peaks associated with BSA at ~3277, 1654, 1457 and 1351 cm⁻¹, which are attributed
189 to O—H stretching, C=O stretching, N—H stretching and C—N stretching vibrations,
190 respectively. Notably, the disappearance of S—H characteristic peaks at ~2525 cm⁻¹
191 indicated that the thiol groups of BSA acted as reductant in the synthesis of AuNCs
192 (Xie, et al., 2018). As for the MoS₂ QDs, apart from the characteristic peaks similar to
193 the AuNCs, the other observed peaks around 3255, 2924, 1064 and 885 cm⁻¹ are
194 assigned to —NH₂, C—H, C—O and C—O—C stretching vibration mode, respectively.
195 The above results confirmed that the surfaces of MoS₂ QDs and AuNCs were modified
196 with active groups. For the MoS₂ QDs-AuNCs composite, the peak intensity of band in
197 1200–1650 cm⁻¹ decreased obviously compared with that of the prepared MoS₂ QDs,
198 which indicates the interaction between MoS₂ QDs and AuNCs.

199 The UV–vis absorption spectrums of the MoS₂ QDs and AuNCs were shown in
200 Fig.1 F. A distinct absorption peak centered near 340 nm could be found in the spectrum
201 of AuNCs, which was assigned to n – π* transitions of C=O groups (Xie, et al., 2018).
202 More importantly, there is a broad absorption at 370–450 nm, which provides
203 conditions for the construction of fluorescence resonance energy transfer (FRET)
204 system. The absorption spectrum of the prepared MoS₂ QDs showed no absorption peak
205 from 500 to 600 nm, this characteristic agrees with the result reported before (Lin, et
206 al., 2019).

207 **3.2 FRET behavior between MoS₂ QDs and AuNCs**

208 A ratiometric fluorescence nanoprobe was developed based on FRET strategy.
209 Fig.2 A shows the fluorescence emission spectrums of the prepared composites under

210 365 nm excitation. The peaks centered at 430 and 615 nm respectively correspond to
211 the PL emission of MoS₂ QDs and AuNCs. Furthermore, the quantum yields (QY)
212 determined for the MoS₂ QDs and AuNCs were 13.4% and 19.6% with quinine sulfate
213 as the standard. The MoS₂ QDs-AuNCs nanocomposite displayed dual emission peaks
214 at 430 and 615 nm. Remarkably, the emission intensity of MoS₂ QDs decreased
215 significantly. Then the effect of AuNCs on fluorescence performance of MoS₂ QDs was
216 explored at 365 nm excitation. As shown in Fig.2 B, the FL intensity of MoS₂ QDs
217 decreased gradually with the addition of AuNCs from 0 to 600 μL, which may be
218 attributed to the occurrence of FRET.

Fig.2

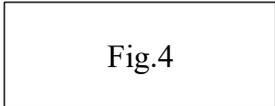

219
220 To prove this conjecture, fluorescence and absorption spectrums of MoS₂ QDs and
221 AuNCs were studied. The efficiency of FRET is dependent upon donor-acceptor
222 proximity (<10 nm) and spectral overlap. As shown in Fig.2 C, the absorption spectra
223 of AuNCs overlapped with the fluorescence emission spectra of MoS₂ QDs from 390
224 nm to 550 nm. On the other hand, according to the TEM image in Fig.1 C, the distance
225 between MoS₂ QDs and AuNCs was less than 10 nm due to the coupling between two
226 fluorophores. The results above confirmed the occurrence of FRET between MoS₂ QDs
227 and AuNCs. Then the fluorescence lifetime of MoS₂ QDs and MoS₂ QDs-AuNCs
228 composites were measured to study the quenching mechanism. As shown in Fig.2 D,
229 the introduction of AuNCs reduced fluorescence lifetime of MoS₂ QDs from 6.97 ns to
230 2.45 ns, indicating the fluorescence quenching of MoS₂ QDs by AuNCs was dynamic
231 quenching.

232 3.3 Effect of nitrite on fluorescence of MoS₂ QDs-AuNCs composite

233 The effect of nitrite on fluorescence of MoS₂ QDs-AuNCs composite and possible
234 sensing mechanism were studied. As shown in Fig.3, under 365 nm excitation, the
235 fluorescence intensity of MoS₂ QDs at 430 nm remained nearly unchanged with the
236 presence or absence of 10 mg/L nitrite. However, the addition of same amount of nitrite
237 induced fluorescence quenching of AuNCs at 615 nm. The quenching mechanism could

238 be attributed to the aggregation of AuNCs caused by the interaction between NO_2^- and
239 BSA ligands coated on the surface of AuNCs, and an effective charge transfer from Au
240 to NO_2^- was built instead of that of BSA-to-Au, leading to the fluorescence quenching
241 of AuNCs (Liu, Yang, Abdel-Halim, & Zhu, 2013; L. Wang, et al., 2019). For the MoS_2
242 QDs-AuNCs system, the fluorescence of AuNCs quenched while that of MoS_2 QDs
243 recovered after adding 10 mg/L of NO_2^- to the system, which may be ascribed to the
244 blocked FRET process resulting from the aggregation of AuNCs. Thus, the detection of
245 nitrite was achieved according to the changes in I_{615}/I_{430} (I_{615} and I_{430} represent the
246 fluorescence intensity at 615 nm and 430 nm). From the above discussion, the
247 schematic diagram for detecting nitrite by employing the proposed MoS_2 QDs-AuNCs
248 system was shown in Fig.4.

249  Fig.3

250  Fig.4

251 3.4 Optimization of the experimental conditions

252 The pH and reaction time were optimized for MoS_2 QDs-AuNCs probe. As shown
253 in Fig.5 A, I_{615}/I_{430} increased with the pH from acidity to weak alkalinity but decreased
254 at strong alkaline condition. This phenomenon may be due to the fact that strong acid
255 or alkali media changed the secondary structure of ligand BSA, which plays a key role
256 in the fluorescence properties of AuNCs (Cao, et al., 2015). Accordingly, weak alkali
257 media of pH 8.5 was optimal for the fluorescent probe. Fig.5 B displayed the effect of
258 reaction time on response of the sensing system exposed to nitrite of 10 mg/L. It can be
259 found the response value (I_{615}/I_{430}) tended to be stable after reaction time of 7 minutes,
260 indicating the reaction has been completed. Therefore, reaction time of 7 minutes was
261 selected for the further experiments.

262  Fig.5

263 3.5 Ratiometric fluorescence detection of nitrite

264 The fluorescence responses of the MoS₂ QDs-AuNCs system in the presence of
265 different concentrations of nitrite were measured under the optimized condition. As
266 shown in Fig.6 A, with increase in nitrite concentration, the fluorescence signal of
267 AuNCs at 615 nm was quenched by nitrite while that of MoS₂ QDs at 430 nm was
268 enhanced. Fig.6 B displayed that the fluorescence intensity ratio of the AuNCs and
269 MoS₂ QDs (I_{615}/I_{430}) decreased gradually with the concentration of nitrite increased
270 from 0-50 mg/L. From the insert of Fig.6 B, a linear calibration can be found in the
271 concentration range of 0.5-20 mg/L with a regression equation of $I_{615}/I_{430} = -$
272 $0.084C+2.693$ (C is the concentration of nitrite in mg/L, $R^2=0.991$). The detection limit
273 for nitrite calculated according to $3\sigma/s$ was 0.67 nM, where σ represents the standard
274 deviation of eight blank measurements, and s is the slope of the calibration curve. More
275 importantly, the fluorescence color change could be observed with increase in nitrite
276 concentration from the insert of Fig.6 A, which renders visual detection of nitrite
277 possible.

Fig.6

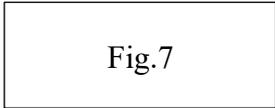

278

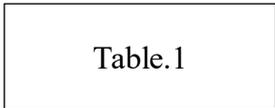

279 3.6 Sensing selectivity

280 To investigate the selectivity of the proposed methods, various interfering
281 substances (including K⁺, Cl⁻, SO₃²⁻, Glu, Ca²⁺, Mg²⁺, H₂PO₄⁻, Fe³⁺, CO₃²⁻, NO₃⁻) were
282 selected to study their effects on the fluorescence responses of the MoS₂ QDs-AuNCs
283 probe. The concentration of nitrite is 10 mg/L while other analytes are fixed at 20 mg/L.
284 Fig.S2 reveals that I_{615}/I_{430} changed obviously in the presence of NO₂⁻ while no
285 significant response changes were observed for the interfering substances compared
286 with the blank control, which may be attributed to the specific interaction between
287 BSA-AuNCs and NO₂⁻. Furthermore, the fluorescence colors of the identical
288 interferences were checked in the same experimental condition. The insert in Fig.S2
289 showed that the interferences have little effect on the fluorescence color of the
290 constructed system, indicating adequate specificity of the proposed method for nitrite.

291 3.7 Fluorescence visualization analysis for nitrite

292 A visualized detection method for nitrite was developed by combining a smart
293 phone with microfluidic chip based on MoS₂ QDs-AuNCs probe. Detailed experimental
294 scheme was depicted in the supplementary materials. The fluorescence color changes
295 from red to blue can be found with increase in nitrite concentration (Fig.7 A). Then the
296 obtained images of “a” channels were extracted from L*a*b mode by image processing
297 functions (Fig.7 B), it is clear that the gray value of “a” channel decreased gradually
298 with increase in nitrite concentration. As shown in Fig.7 C, the average “a” value
299 exhibited a linear response to the nitrite concentration in the range of 1.0-20 mg/L. the
300 regression equation can be express as $y=-1.045x+25.173$ ($R^2=0.994$), and the detection
301 limit for nitrite is 27.32 nM. The sensing performances of prepared MoS₂ QDs-AuNCs
302 system were compared with several previous reports. As shown in Table.1, the
303 performance parameters of MoS₂ QDs-AuNCs system are comparable or better than
304 those of reported probes. The above results reveal potential of the prepared MoS₂ QDs-
305 AuNCs system for nitrite detection.

306  Fig.7

307  Table.1

308 3.8 Nitrite detection in sausage samples

309 In order to evaluate the practicability of the established methods, the ratiometric
310 MoS₂ QDs-AuNCs probe and prepared microfluidic chip were applied to detect nitrite
311 in sausage. Different amounts of nitrite standard solution (0.0, 5.0, 10.0, 15.0 mg/L)
312 were spiked to the pretreated sample solutions before determination. The results are
313 shown in Table.2. It is observed that the recoveries of the spiked samples for
314 fluorescence method varied from 102.6% to 108.2% and for visualized analysis ranged
315 from 104.6% to 110.8%, and the relative standard deviations (RSD) were below 2.6 %,
316 indicating that the proposed methods can be applied to practical detection of nitrite in
317 sausage samples.

Table.2

318

319 **4 Conclusion**

320 In summary, a ratiometric fluorescence probe based on FRET between MoS₂ QDs
321 and AuNCs was developed for nitrite detection in sausage. With the addition of nitrite,
322 the fluorescence of AuNCs was quenched, and further caused the fluorescence recovery
323 of MoS₂ QDs due to the blocked FRET. With this strategy, nitrite could be detected
324 with high sensitivity, good selectivity and low detection limit. Furthermore, according
325 to the color changes of the fluorescence probe, a microfluidic chip was employed to
326 achieve visualized detection of nitrite over a range from 1.0 to 20 mg/L. Finally, the
327 proposed fluorescent and visualized methods were successfully applied to the
328 determination of nitrite in sausage samples, indicating the potential for practical
329 application.
