1

2 **Figure 1.** a) Location of the different volcanic zones of the Andes. b) Location of the four  
 3 subdivisions of the Southern Volcanic Zone. c) The Central Southern Volcanic Zone and  
 4 location of stratovolcanoes and the Liquiñe-Ofqui Fault Zone (LOFZ). Location of the LOFZ  
 5 (solid and dashed lines) inferred from Cembrano et al. (1996) and Cembrano and Lara (2009).

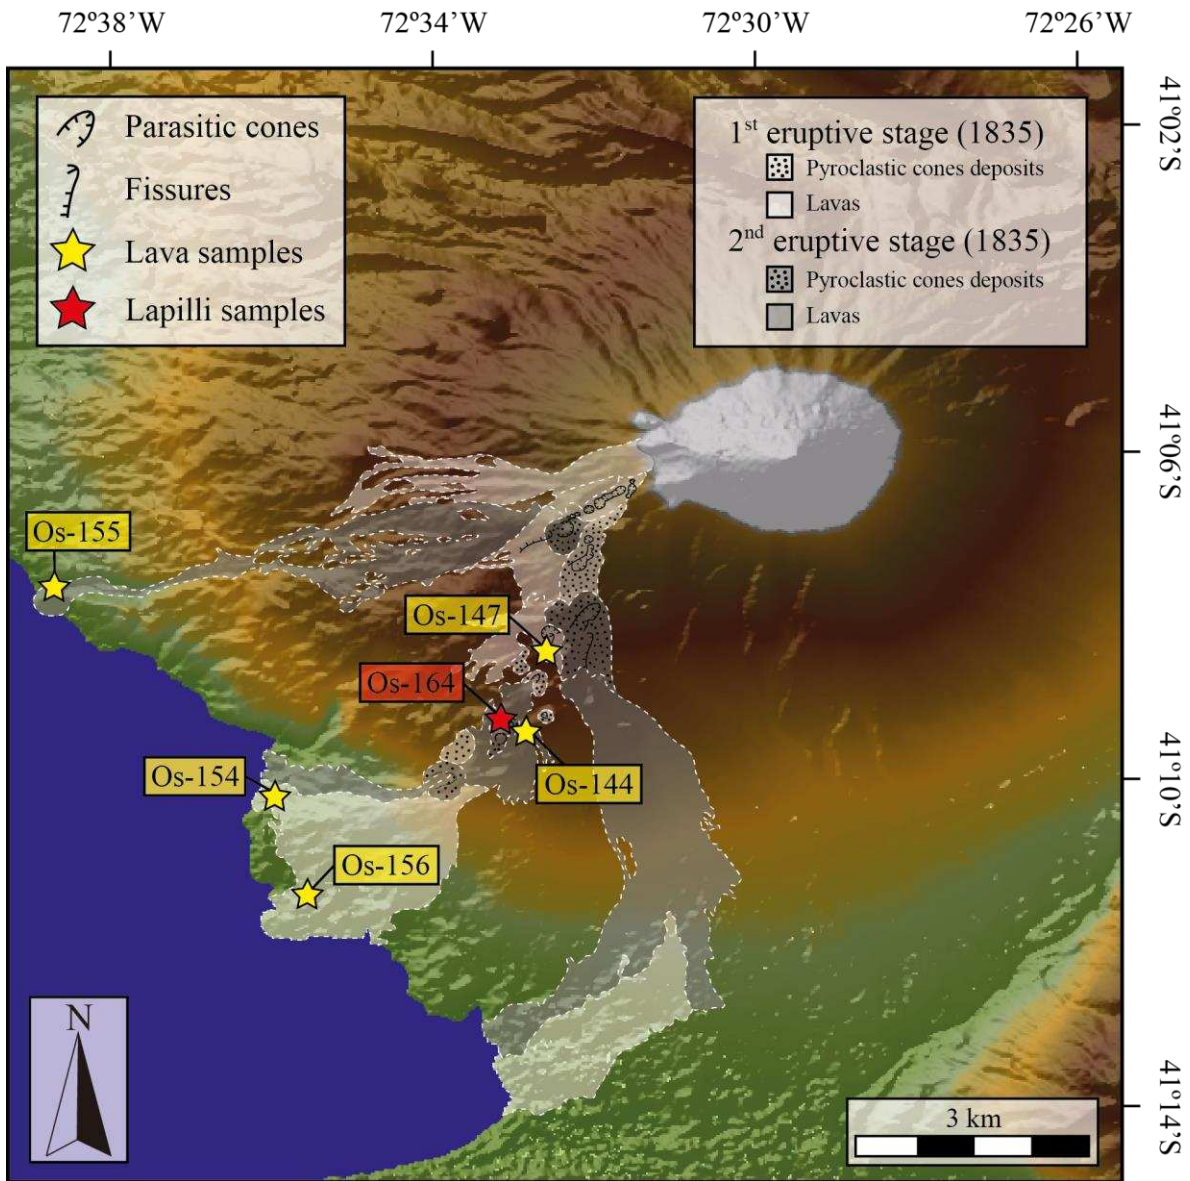

6

7

8 **Figure 2.** (a) Location of the Osorno volcano in Chile. (b) Location of Osorno, La Picada,  
 9 Puntigudo, and Calbuco volcanoes and Cordón Cenizos volcanic chain, La Viguera cone,  
 10 and the Liquiñe-Ofqui Fault Zone (LOFZ, white dashed line). The alignment of Osorno, La  
 11 Picada, Puntigudo and Cordón Cenizos is represented by a yellow, dashed line. Advanced  
 12 Spaceborne Thermal Emission and Reflection Radiometer (ASTER) Global Digital  
 13 Elevation Model (GDEM) image was obtained via EarthExplorer, USGS  
 14 (<http://earthexplorer.usgs.gov>).

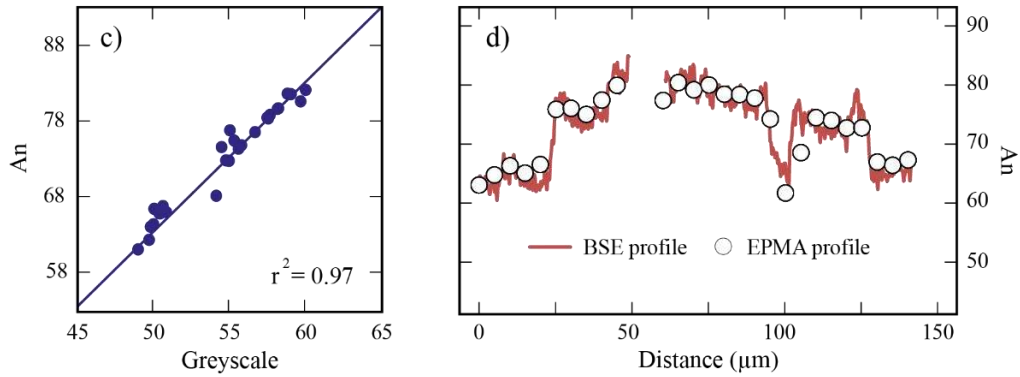

15

16

17 **Figure 3.** Osorno volcano and the deposits of the first and second stages of the 1835 eruption.  
 18 Yellow stars represent locations where samples are collected from a lava flow, whereas lapilli  
 19 sample locations are represented by red stars. Locations and dates of the lava flows and fall  
 20 deposits are based on Moreno et al. (2010) and Lara et al. (2012). ASTER–GDEM image  
 21 from EarthExplorer, USGS (<http://earthexplorer.usgs.gov>).

22

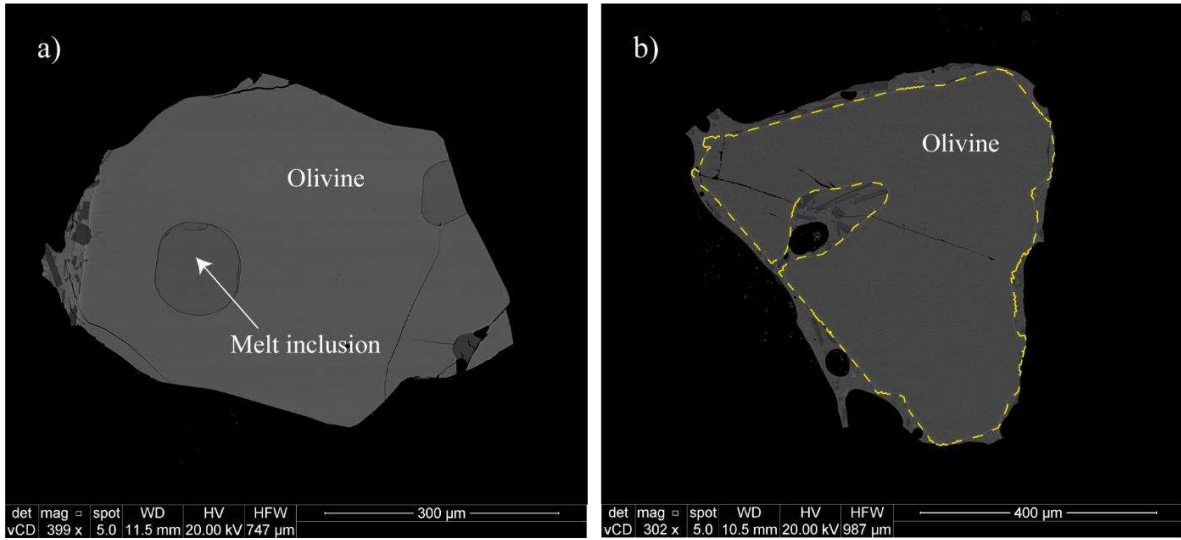

23

24 **Figure 4.** (a) Backscatter electron (BSE) images of an isolated plagioclase phenocryst where  
 25 different compositional zones are found. Brighter greyscale colours are correlated to higher  
 26 density. (b) The arrow represents the profile measured by electron probe micro-analysis  
 27 (EPMA) and its direction. (c) Relation and coefficient of determination ( $r^2$ ) between BSE  
 28 greyscale profile and the measured anorthite content ( $An = 100 \times Ca / (Ca + Na + K)$ ; in molar  
 29 proportions). “An” is a representative description of the composition of plagioclase because  
 30 in all crystals the K content remains constant throughout (details in Supplementary Data 2).  
 31 (d) Anorthite profile composition (An) by EPMA of the measured profile (circles) coupled  
 32 with the BSE profile based on greyscale values calibrated with the composition measured by  
 33 electron microprobe (solid line).

34

35

36

37 **Figure 5.** (a) Olivine-hosted melt inclusion of ~110  $\mu\text{m}$  diameter. (b) Resorption feature  
38 (embayment) in olivine phenocryst with glass and plagioclase microlites. The yellow dashed  
39 line represents the olivine grain boundary.

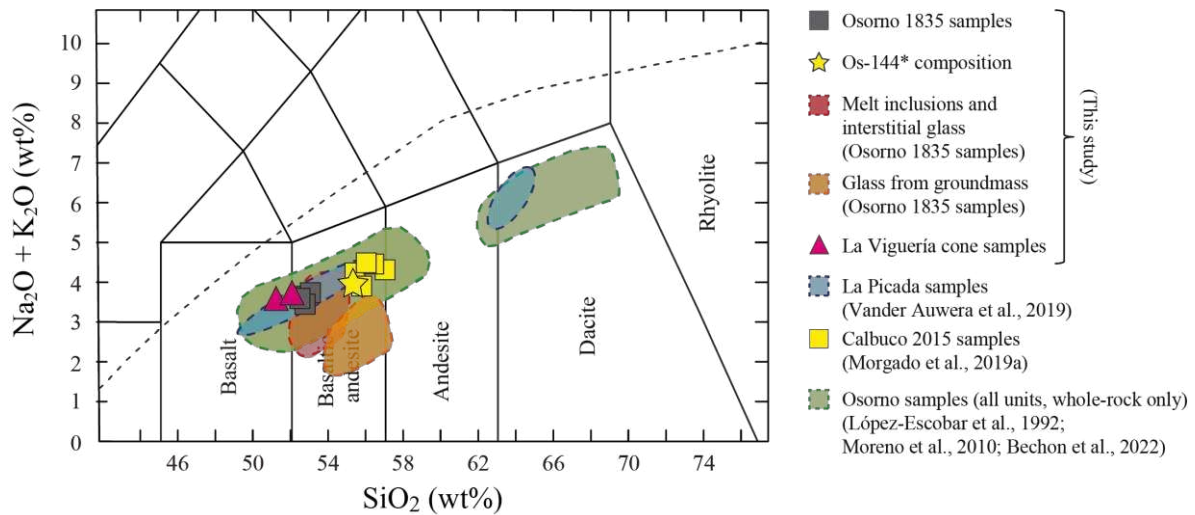

40

41

42 **Figure 6.** (a) BSE image of a crystal clot of olivine grains. (b) Zoom of the BSE image,  
43 which shows interstitial glass between the crystals constituting the clot. (c) EBSD map  
44 represents the diversity of olivine crystal orientations, consistent with the observation that  
45 the glasses are interstitial and are not melt inclusions.

46

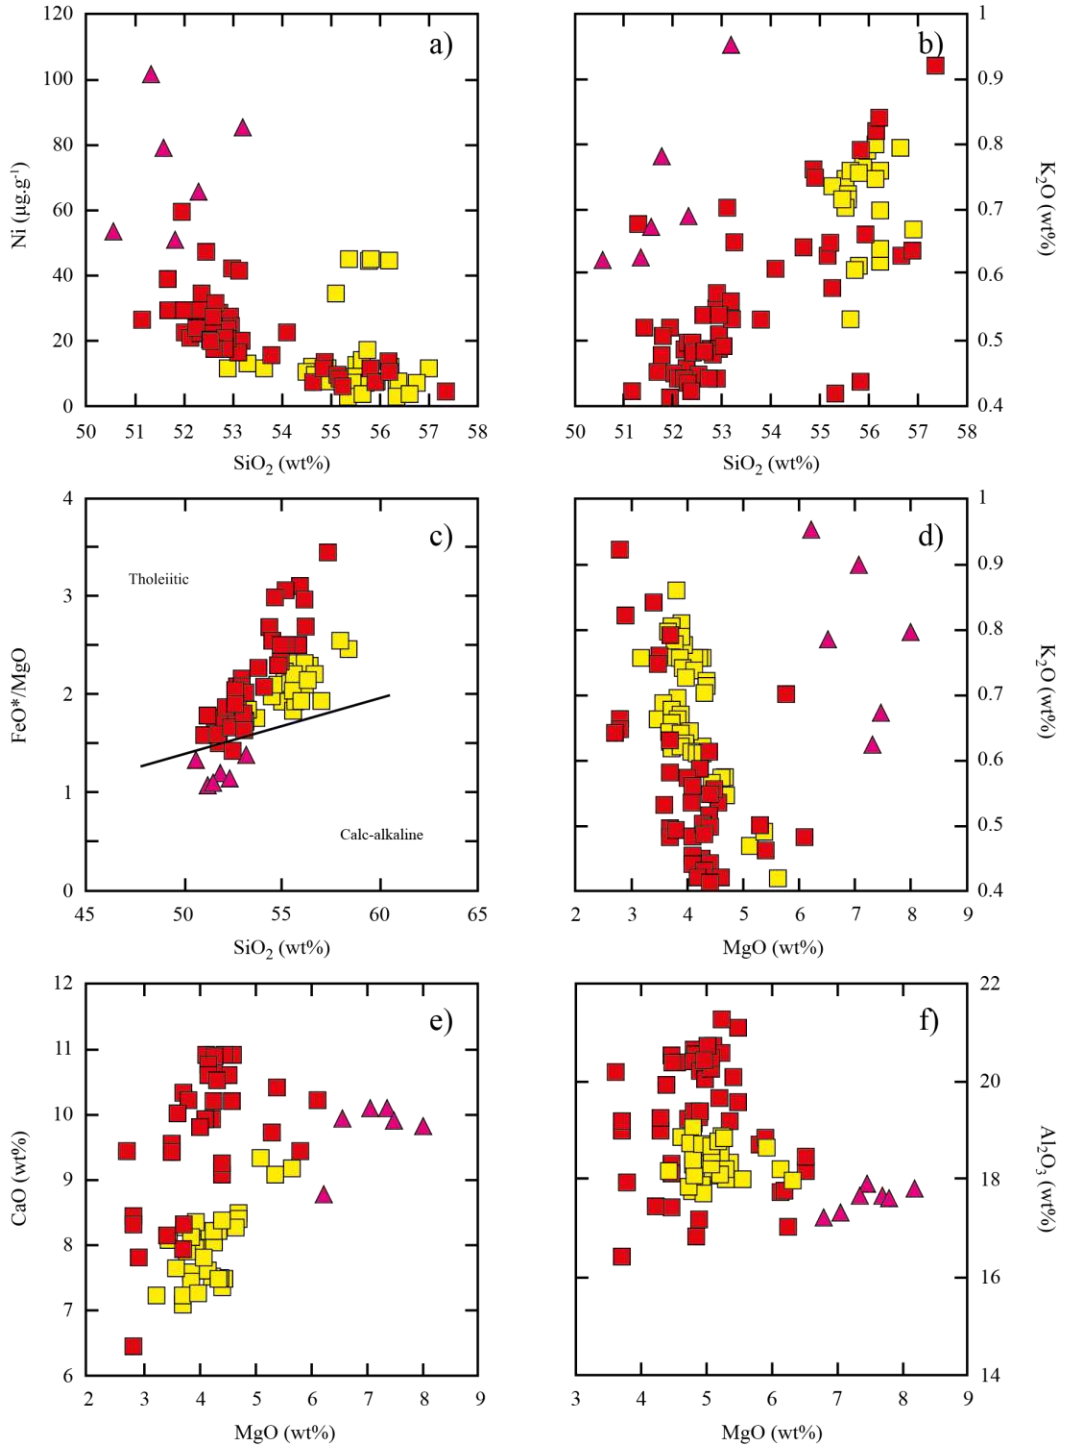

47

48 **Figure 7.** Total alkali versus silica (Le Bas et al., 1986) plots of the Osorno 1835 volcanic  
 49 products (grey squares), the modified composition of Os-144 (Os-144\*, yellow star), melt  
 50 inclusions (Group 1 of glass, red field), and glass from groundmass (Group 2 glass, green  
 51 field), La Viguera cone products (pink triangles), La Picada volcanic products (Vander  
 52 Auwera et al., 2019, blue field), and Calbuco 2015 volcanic products (Morgado et al., 2019a,  
 53 yellow squares).

54

- Calbuco samples (Castruccio et al., 2016; Morgado et al., 2019a; Arzilli et al., 2019; Namur et al., 2020)
- Osorno samples (Tagiri et al., 1993; Moreno et al., 2010; Bechon et al., 2022; this study)
- ▲ Cayutué-La Viguería field samples (López-Escobar et al., 1995b; this study)

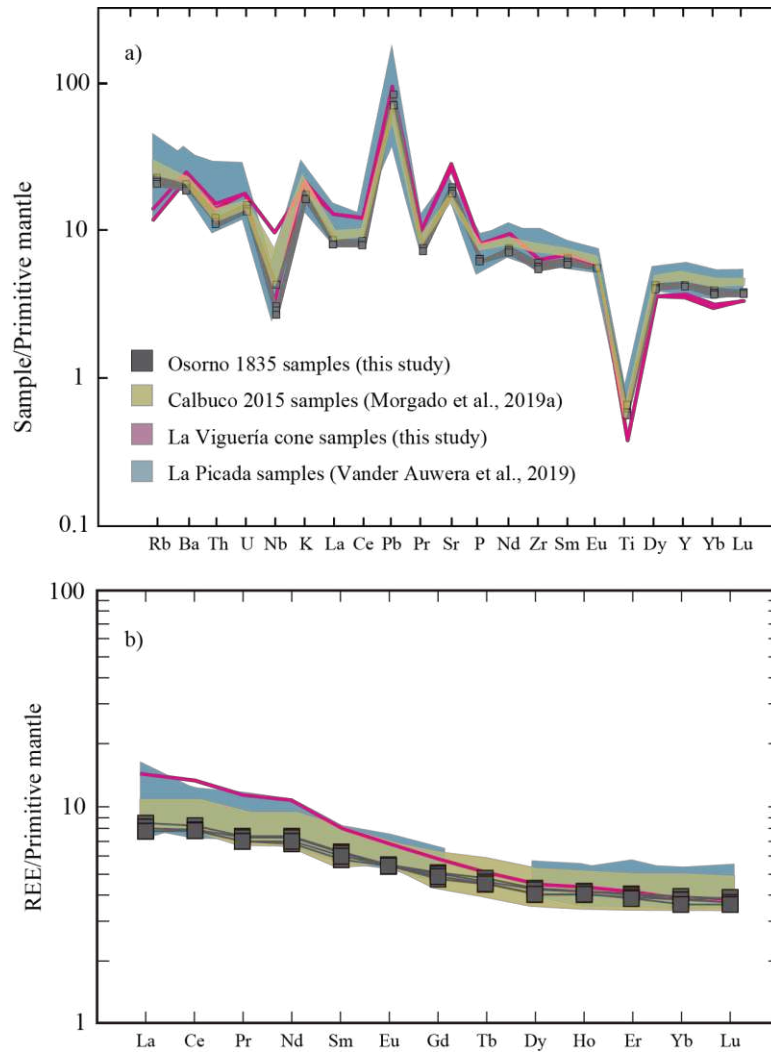

55

56

57 **Figure 8.** (a) Variations of Ni ( $\mu\text{g}\cdot\text{g}^{-1}$ ) versus SiO<sub>2</sub> (wt. %), (b) K<sub>2</sub>O (wt. %) versus SiO<sub>2</sub> (wt.  
58 %), (c) FeO\*/MgO versus SiO<sub>2</sub> (wt. %), (d) K<sub>2</sub>O (wt. %) versus MgO (wt. %), (e) CaO (wt.  
59 %) versus MgO (wt. %), and (f) Al<sub>2</sub>O<sub>3</sub> (wt. %) versus MgO (wt. %) of Holocene erupted  
60 products from Calbuco volcano (Castruccio et al., 2016; Morgado et al., 2019a; Arzilli et al.,  
61 2019; Namur et al., 2020), Osorno volcano (Tagiri et al., 1993; **Moreno et al., 2010; Bechon**  
62 **et al., 2022;** this study), and Cayutué-La Viguería field (López-Escobar et al., 1995a; this  
63 study).

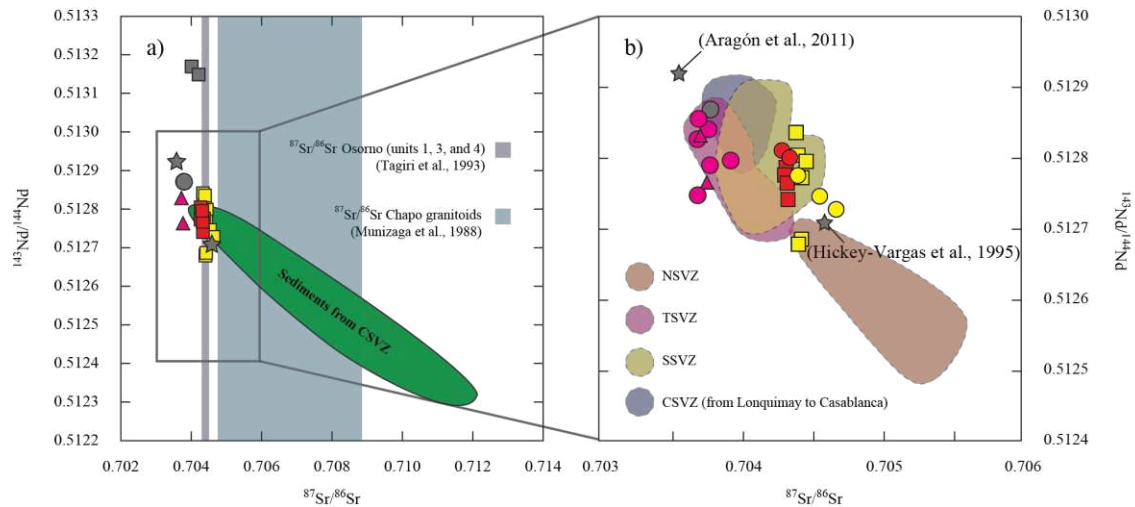

64

66

67 **Figure 9.** (a) Primitive mantle-normalised (Sun and McDonough, 1989) incompatible trace  
 68 element diagram for Calbuco erupted products, taken from López-Escobar et al. (1995b)  
 69 Morgado et al. (2019a). Major and trace element concentrations from Osorno and La  
 70 Viguera are available in Table 2. (b) REE patterns of bulk rock samples from volcanic  
 71 systems of the region (La Viguera, Osorno, Calbuco, and La Picada volcanoes).

72

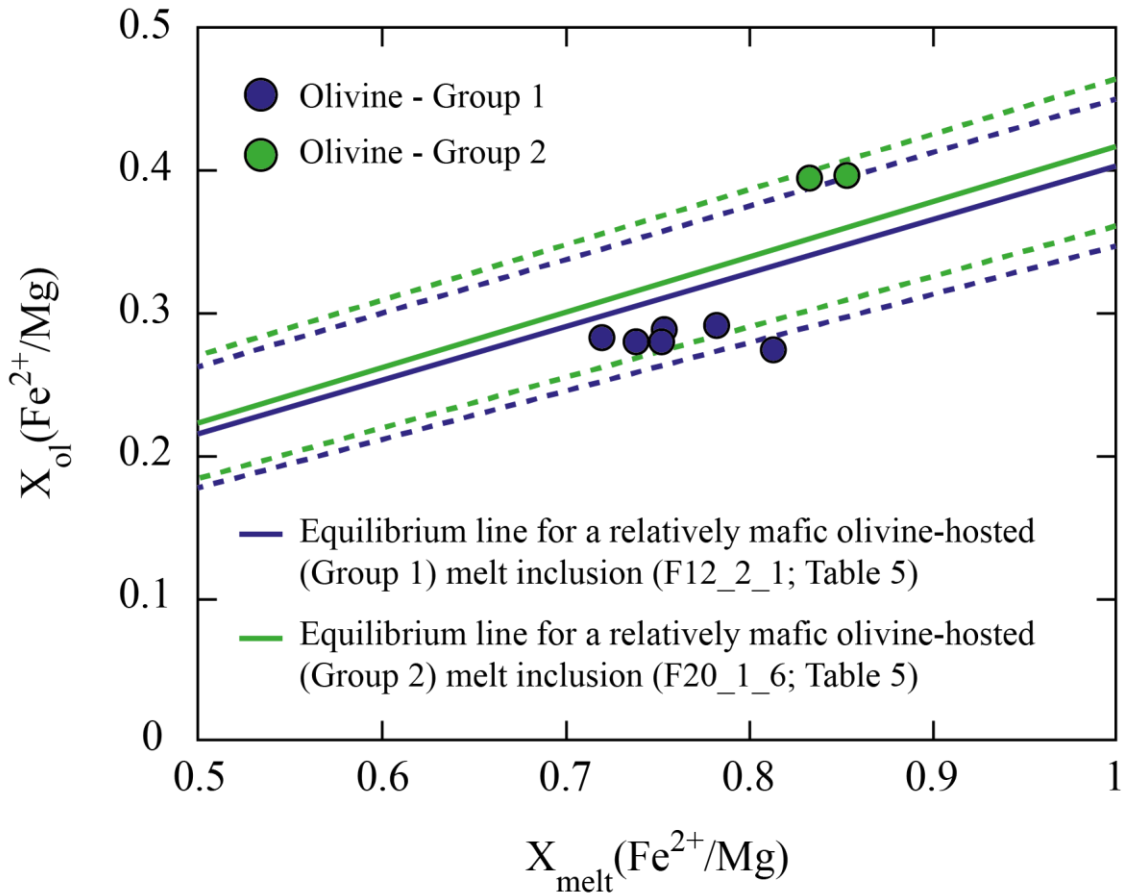

- Granulite xenoliths (Hickey-Vargas et al., 1995)
- ★ Gabbro xenoliths (Hickey-Vargas et al., 1995; Aragón et al., 2011)
- Granitoids (Aragón et al., 2011)
- Sediments from CSVZ trench (Kilian and Behrmann, 2003; Jacques et al., 2014)
- Osorno (this study)
- Osorno (Jacques et al., 2014)
- Calbuco (this study)
- Calbuco (López-Escobar et al., 1995)
- ▲ La Viguera cone (this study)
- Cayutué-La Viguera volcanic field (López-Escobar et al., 1995)

73

74 **Figure 10.** (a)  $^{144}\text{Nd}/^{143}\text{Nd}$  versus  $^{87}\text{Sr}/^{86}\text{Sr}$  of volcanic products of Osorno, Calbuco,  
 75 sediments from the CSVZ trench, granulite xenoliths, gabbro xenoliths and from the  
 76 basement, and granitoids from basement. (b) Comparison of  $^{144}\text{Nd}/^{143}\text{Nd}$  versus  $^{87}\text{Sr}/^{86}\text{Sr}$   
 77 with other volcanic zones from the SVZ (from Hickey-Vargas et al., 2016a and references  
 78 therein).

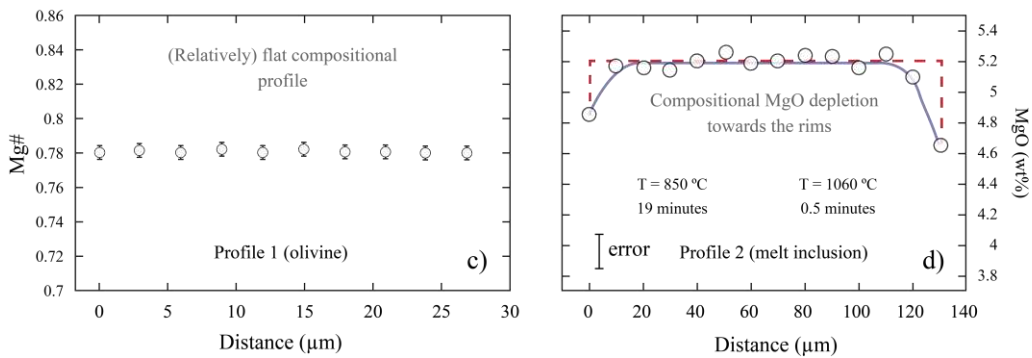

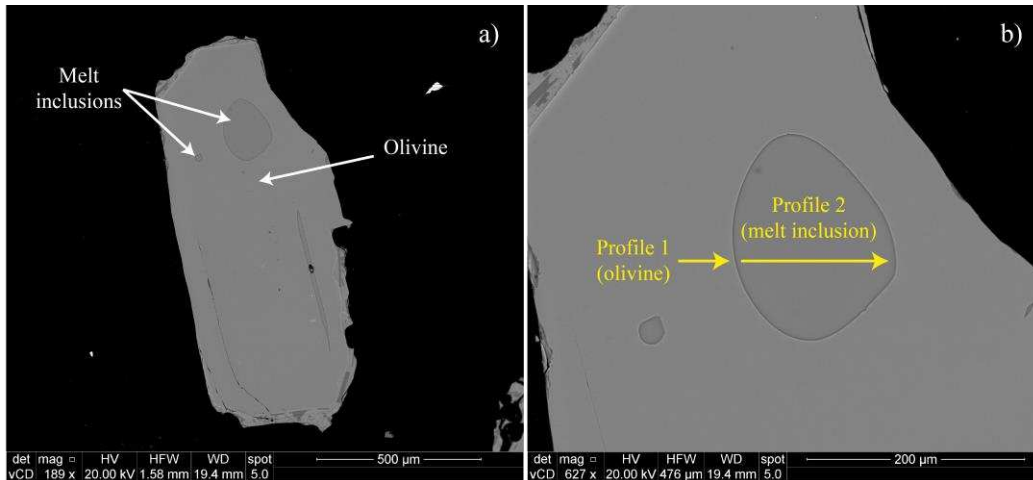

79

81

82 **Figure 11.** Olivine core compositions ( $X_{ol}(Fe^{2+}/Mg)$  vs  $X_{melt}(Fe^{2+}/Mg)$ ) for products of the  
 83 1835 Osorno eruption. Most of the olivine compositions from group 1 (Fo<sub>76-79</sub>) are in  
 84 equilibrium with the hosted melt inclusions, whereas the two olivine crystals from group 2  
 85 (Fo<sub>69-73</sub>) are in equilibrium with the hosted melt inclusions. The Fe<sup>2+</sup> in the melt is calculated  
 86 using the olivine-hosted spinel inclusions Fe<sup>2+</sup>/Fe<sup>3+</sup>. We calculate the equilibrium lines as  
 87  $X_{ol}(Fe^{2+}/Mg) = K_D \times X_{melt}(Fe^{2+}/Mg)$ , where  $K_D$  is calculated via the Toplis (2005) procedure.  
 88 Dashed lines represent the uncertainty of the Toplis (2005) method.

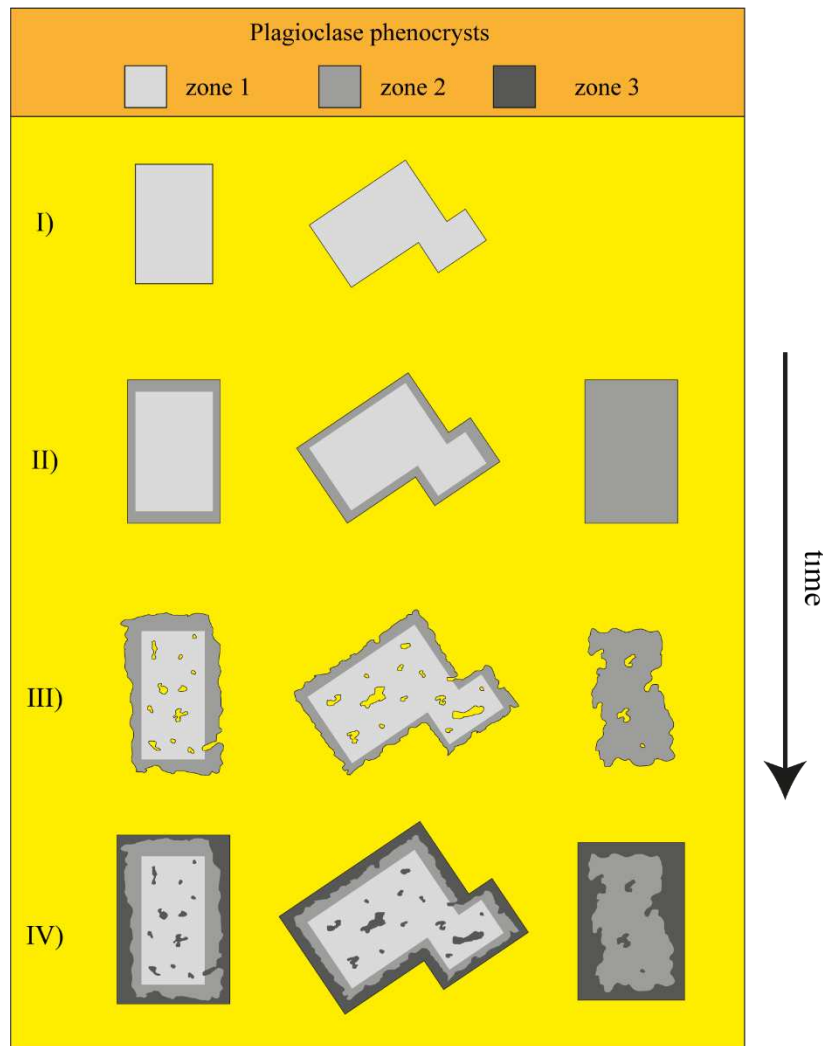

89

90

91 **Figure 12.** (a) BSE image of an olivine phenocryst and melt inclusions. (b) Zoom of the BSE  
 92 image, which shows the EPMA profiles in olivine and large melt inclusion. (c) Mg#  
 93 composition of olivine phenocryst traverse, which is flat (showing the absence of  
 94 disequilibrium), (d) MgO (wt. %) composition profiles of the melt inclusion shown in b),  
 95 which show depletion towards the rim. That depletion represents diffusion and the related  
 96 timescales are a few minutes.

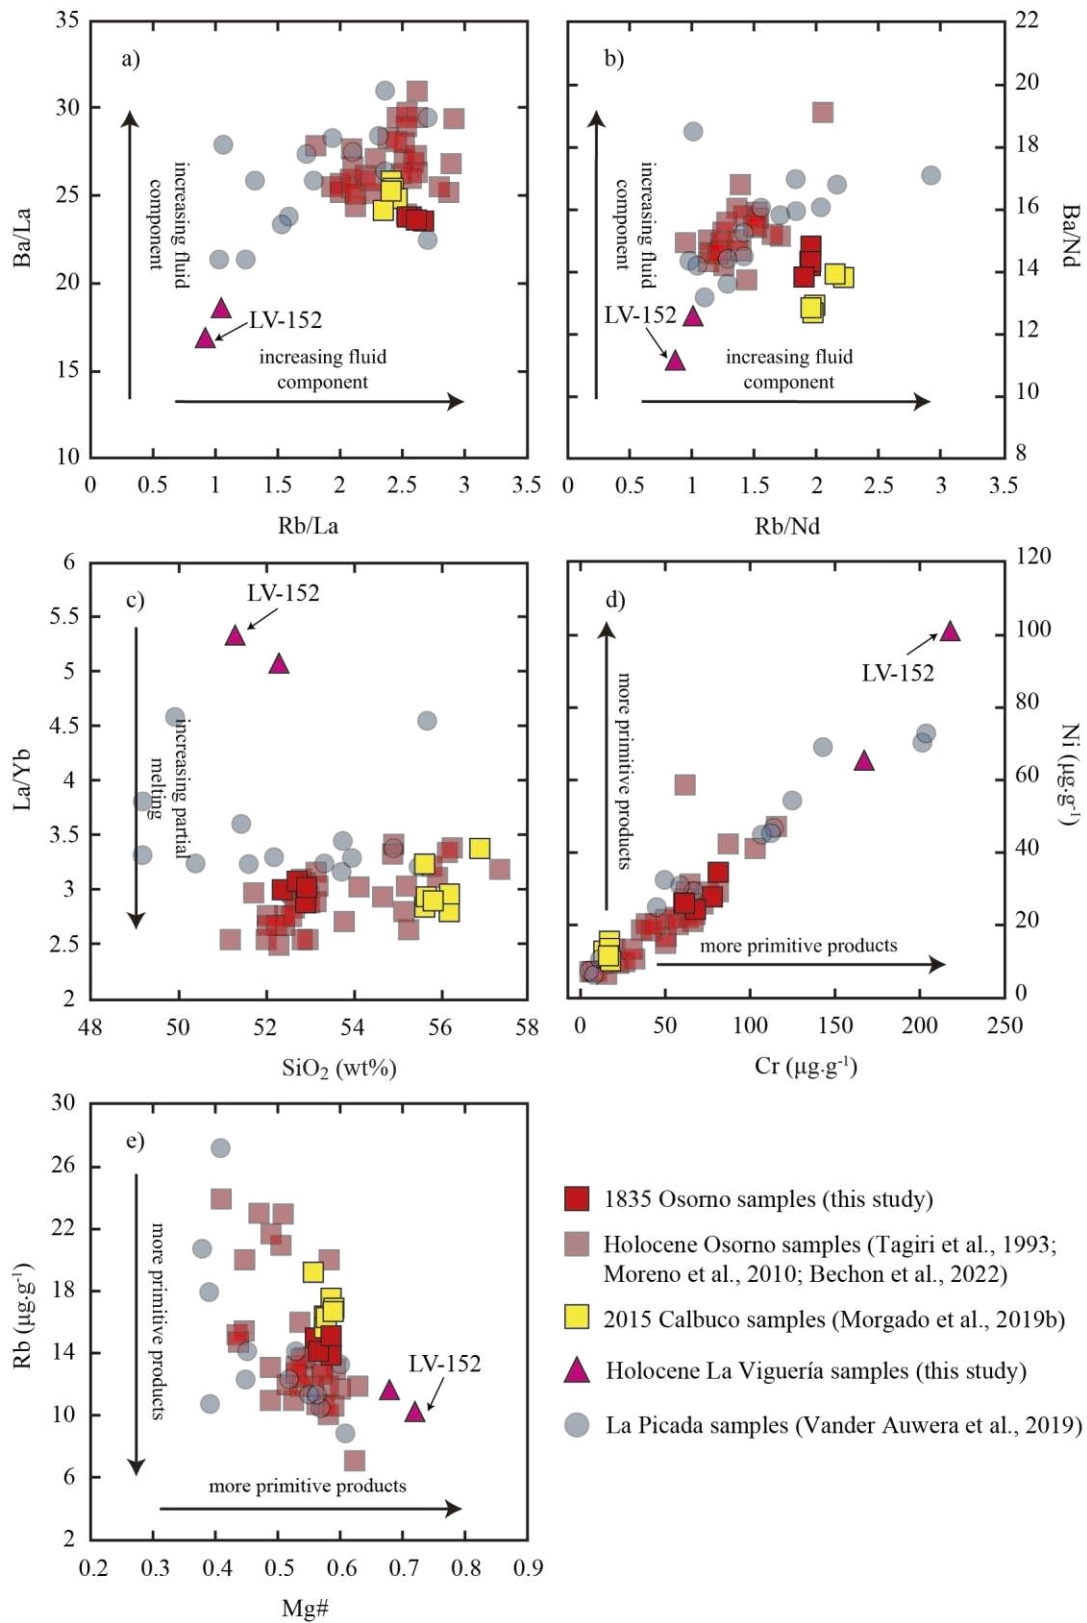

97

98

99 **Figure 13.** Evolution of plagioclase phenocrysts zoning over time: first event (I) is nucleation  
100 and growth of plagioclase phenocryst cores (Zone 1 composition); after that (II), growth of  
101 plagioclase phenocryst rims and nucleation and growth of new plagioclase phenocrysts  
102 occurred (Zone 2 composition). These two first crystallization events occurred during the  
103 crystal mush formation. After the crystal mush building, another process generating  
104 plagioclase-melt disequilibrium and resorption (we suggest volatile additions or heating)  
105 occurred (III), and finally (IV), a last growth event occurred. We infer that the last growth  
106 event occurred before or during the eruption triggering.

107

108

109 **Figure 14.** Plots of fluid mobile/immobile elements of **Holocene** volcanic samples of the  
 110 region: (a) Ba/La versus Rb/La and (b) plot of Ba/Nd versus Rb/Nd. (c) plot of La/Yb versus

111 SiO<sub>2</sub>. (d) plot of Ni ( $\mu\text{g}\cdot\text{g}^{-1}$ ) versus Cr ( $\mu\text{g}\cdot\text{g}^{-1}$ ). (e) plot of Rb ( $\mu\text{g}\cdot\text{g}^{-1}$ ) versus Mg#. In a) and  
112 b) the arrows represent the direction in which the fluid component in the source is increasing.  
113 In c) the arrow represents the direction in which partial melting degree of the source is  
114 increasing. The arrows in d) and e) represent the direction in which the products are more  
115 primitive. We calculated Mg# assuming  $\text{Fe}^{2+}/\text{Fe}^{3+} \approx 3$  (the same ratio we reported in this  
116 article via titration) in those samples from studies in which only  $\text{Fe}_2\text{O}_{3(t)}$  is reported (Moreno  
117 et al., 2010; Bechon et al., 2022).

118

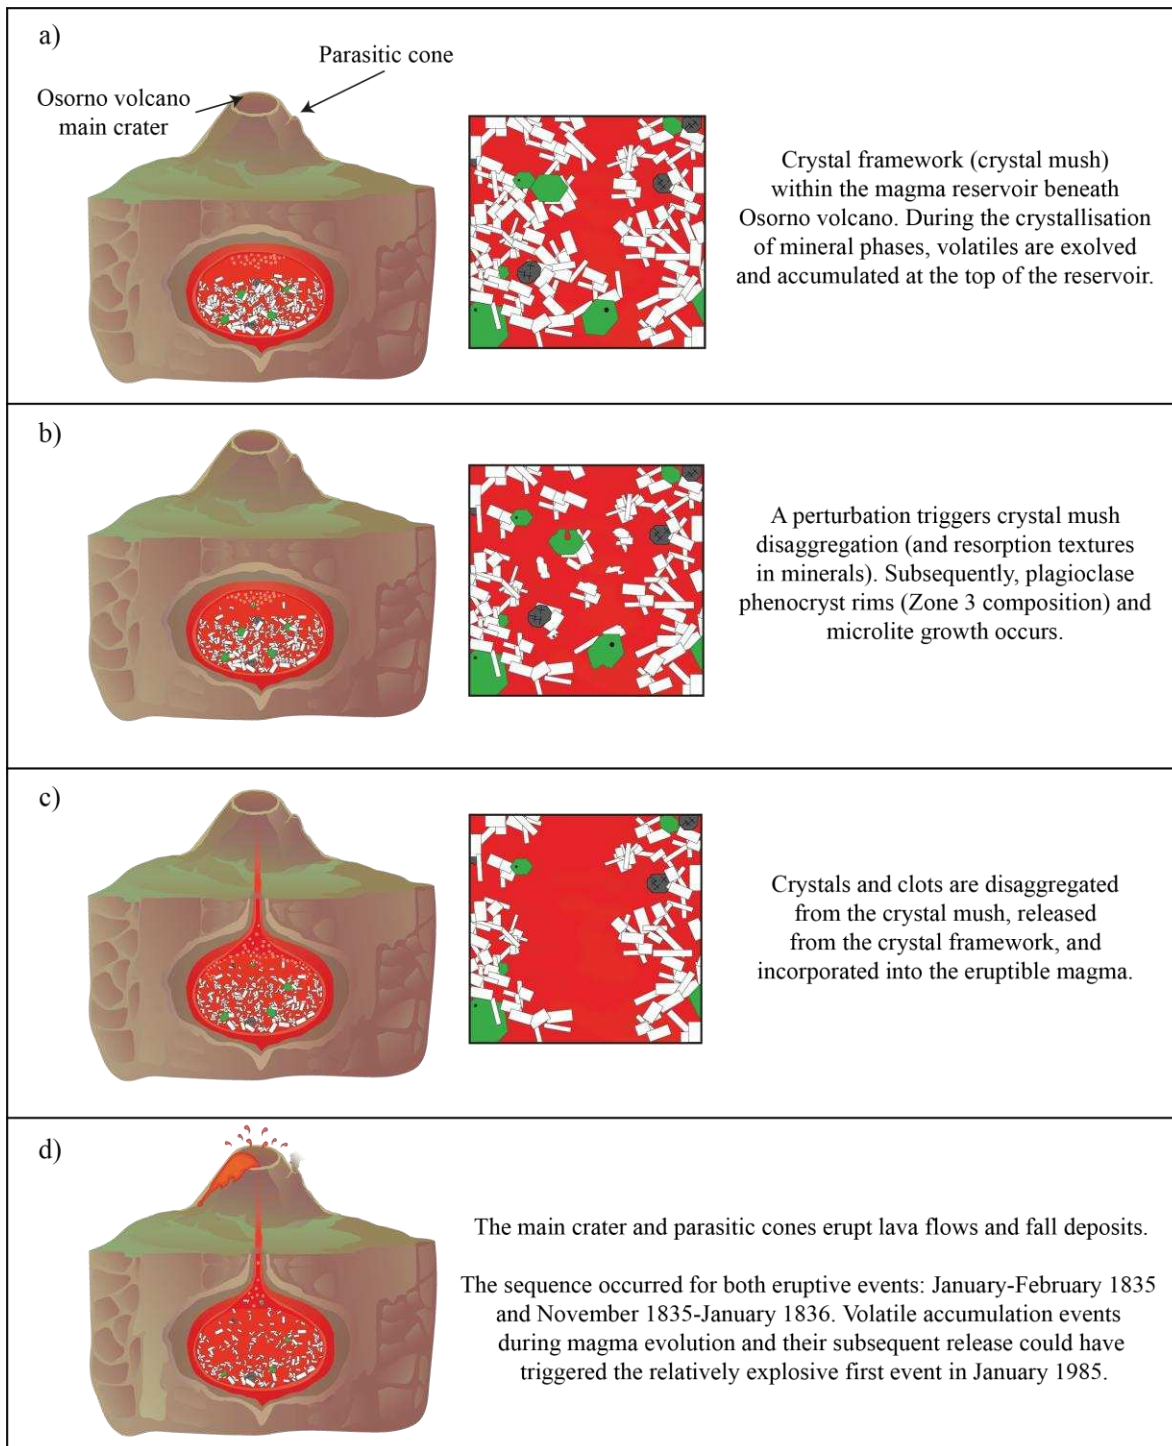

119

120 **Figure 15.**  $^{143}\text{Nd}/^{144}\text{Nd}$  vs.  $^{87}\text{Sr}/^{86}\text{Sr}$  of whole-rock compositions of the samples from the  
 121 regional crustal rocks (granulite, gabbro, and granitoids; Hickey-Vargas et al., 1995; Aragón  
 122 et al., 2011), Calbuco and Osorno stratovolcanoes, La Viguera small eruptive centre, and  
 123 samples representing mantle compositions (DMM and EM-I; Workman and Hart, 2005;  
 124 Garapić et al., 2015) and mixing lines showing possible fluid composition supplies  
 125 considering the ranges of  $^{87}\text{Sr}/^{86}\text{Sr}$  ratio and  $^{143}\text{Nd}/^{144}\text{Nd}$  for trench sediments in Kilian and  
 126 Behrmann (2003). The sediment compositional end-members are modelled in a) and b),

127 respectively. The mixing lines are built according to the isotopic values presented in Table  
128 3.

129

130

131 **Figure 16.** Schematic representation of the evolution of the shallow reservoir beneath Osorno  
 132 volcano before the 1835 eruption. Figure (a) shows the initial crystal mush, which is  
 133 perturbed (by heating and/or volatile addition), as represented in Figure (b). Figure (c) shows  
 134 how crystals are disaggregated from the crystal mush and incorporated to the eruptible  
 135 magma. Figure (d) shows when the eruption is triggered, it occurs in the main crater as well  
 136 as the parasitic cones (image not to scale). The main crater and parasitic cones erupt lava

137 flows and fall deposits. The sequence occurred for both eruptive events: January-February  
138 1835 and November 1835-January 1836. Volatile accumulation events during magma  
139 evolution and their subsequent release could have triggered the relatively explosive first  
140 event in January 1985.
