1 **Creation of rapeseed germplasm with high**  
2 **polyunsaturated fatty acid content by relative**  
3 **introgression of *Brassica carinata***

4 Dear Editor,

5 *Brassica napus* L., commonly known as rapeseed, canola or oilseed rape,  
6 is the world's third oilseed crop and accounts for ~12% of major worldwide oil  
7 production (FAO., 2022). Rapeseed provides not only healthy and nutritionally  
8 balanced edible oil for humans, but also protein-rich fodder for animals, and  
9 renewable materials for biodiesel and industrial applications. Polyunsaturated  
10 fatty acids (PUFAs), including omega-3 fatty acids and omega-6 fatty acids,  
11 are mainly essential fatty acid and play a crucial role in the human diet, and  
12 humans obtain these fatty acids through dietary sources. Most crop seeds and  
13 vegetable oils, including canola, soybean, corn, and sunflower oils, are major  
14 sources of omega-6 fatty acids in the form of linoleic acid with low proportions  
15 of omega-3 fatty acids (Saini and Keum, 2018). There are several key genes  
16 responsible for PUFAs, such as *FAD2*, which converts oleic acid to linoleic  
17 acid and *FAD3*, which converts linoleic acid to linolenic acid (Okuley et al.,  
18 1994; Yadav et al., 1993).

19 As a young allotetraploid species formed by interspecific crosses  
20 between the diploid ancestors of *B. rapa* ( $2n = 20$ , AA) and *B. oleracea* ( $2n =$   
21  $18$ , CC), *B. napus* ( $2n=38$ , AACCC) has a limited genetic diversity due to the  
22 short history of cultivation and domestication and long-term double-low  
23 breeding (Allender and King, 2010; Friedt and Snowdon, 2010; Prakash et al.,  
24 2011). Wild relatives and other related genetic resources represent a  
25 favorable genetic variation that can be exploited to develop climate-resilient  
26 modern crops (Wang et al., 2020; Zhou et al., 2021). During the process of  
27 interspecific hybridization, exotic introgression occurs as a natural gene flow  
28 and it not only introduces new genetic variations but also increases the

29 complexity of crop genomes. However, how to mine the elite or favorable  
30 genetic variation with mixed genomic variations and introgression is a  
31 challenge. Therefore, we aim to explore the novel germplasm harboring rich  
32 exotic introgression with more efficiency and provide insights for explaining  
33 the regulatory mechanisms for exotic introgression and genomics-assisted  
34 wild relative introgression.

35 To broaden the genetic basis of rapeseed, through interspecific crosses  
36 between 75 *B. carinata* accessions and 122 *B. rapa* accessions, we obtained  
37 more than 20,000 lines of new-type *B. napus* gene pool (Hu et al., 2019; Zou  
38 et al., 2018). From the gene pool of new-type *B. napus*, we select one line  
39 called HLL45 with five large-scale homoeologous exchange (HE) including  
40 C5/B1, A2/C2, A3/C3, A4/C4 and A9/C8 (Figure 1A, Supplemental Figure 1).  
41 Interestingly, HE between C5/B1 resulted in an introgression fragment with  
42 more than 5Mb on C5 from B1 chromosome of *B. carinata* (Supplemental  
43 Figure 1). We investigated agronomic traits and quality traits for HLL45 and  
44 found that it is a novel germplasm of high polyunsaturated fatty acid (PUFA)  
45 content at 40%~45%, including linoleic acid (LEI) and linolenic acid (LEN)  
46 content. Compared to conventional *B. napus* varieties, the PUFA content of  
47 HLL45 was 15 percentage higher, mainly contributed by LEI, but its seed oil  
48 content decreased (Figure 1B and Supplemental Table 1). Our lines should  
49 therefore be considered pre-breeding material, from which new elite cultivars  
50 can be developed. Using a genetic map constructed by HG DH population  
51 (Hu et al., 2024), we identified a major QTL, *qFA-C5-4*, that explained 63.2%-  
52 64.6%, 37.3%-73.3%, and 7.4% of the phenotypic variation for oleic acid  
53 content (OLE), LEI and LEN, respectively (Figure 1B, Supplemental Figure 2  
54 and Supplemental Table 2-5). Notably, the markers defining QTL *qFA-C5-4*  
55 were located in the *B. carinata* B1 segment introgression region on  
56 chromosome C5, which contains an orthologue of the *FAD2* gene, which  
57 encodes the enzyme that converts OLE to LEI (Supplemental Figure 2).  
58 Therefore, PUFA content in rapeseed appears to be associated with the B1

59 introgression from *B. carinata*.

60 To comprehensively study the characteristics and effect of exotic  
61 introgression, we assembled four high-quality genomes including HLL45 and  
62 its representational parents (Supplemental Figure 3 and 4) by a combination  
63 of Illumina short reads, Oxford Nanopore Technology (ONT) long reads, Hi-C  
64 reads and genetic map. The assembled genome for HLL45 comprised 344  
65 contigs (N50, 18.0 Mb) and had a total size of 927 Mb, with high BUSCO  
66 completeness at 99.0% and a mapping rate of 99.7% from short reads,  
67 leading to a highly accurate and nearly complete assembly (Supplemental  
68 Figure 4 and Supplemental Table 6). We successfully anchored 99.0% of the  
69 contigs to 19 pseudochromosomes exhibiting good collinearity with HG  
70 genetic map (Hu *et al.*, 2024), and annotated 101,495 protein-coding genes  
71 for HLL45 (Supplemental Figure 5 and Supplemental Table 6). We identified a  
72 total of 11,611 exotic genes with mainly on A05 and C07 in HLL45, including  
73 4,538 genes from *B. rapa* and 7,073 genes from *B. carinata*. Among exotic  
74 genes from *B. carinata*, 1,043 genes and 5,919 genes were exotic genes from  
75 B and C sub-genome respectively, with the rest genes coming from  
76 unanchored sequences. 80% of exotic genes from B sub-genome of *B.*  
77 *carinata* were located on chromosome C5 and were mainly enriched in fatty  
78 acid metabolism, unsaturated fatty acids biosynthesis and linoleic acid  
79 metabolism (Figure 1D). For the major QTL *qFA-C5-4* located in the 1.34 Mb  
80 region (50.0 Mb ~ 51.4 Mb) of C5 in HLL45 genome, there were 217 genes in  
81 the region and 131 genes were different expressed genes in all of 10 different  
82 seed development stages between HLL45 and ZS11 (Figure 1E and  
83 Supplemental Figure 6). *BcaFAD2.B1* (BnaHLLC05G045860) had the highest  
84 expression in seeds, and co-expression network analysis indicated that it was  
85 the hub gene of PUFA (Supplemental Figure 7). We identified a six-Mb exotic  
86 introgression on C5 (from 49.9 Mb to 55.9 Mb) in HLL45 from B1 of *B.*  
87 *Carinata*, showing the *FAD2* on C5 was replaced by *BcaFAD2.B1* (Figure 1F).  
88 Lines in HG population carrying the C5 SV contained 8.56% higher LEI than

89 those lines with no SV (Figure 1G and Supplemental Table 7). We further  
90 confirmed SV on C5 was stably inheritable (Supplemental Figure 8). In the  
91 HG population, the high-LEI lines carried the *BcaFAD2.B1* and C5 SV while  
92 the low-LEI lines did not (Figure 1H and Supplemental Table 8). These results  
93 implicate the six-Mb exotic introgression on C5 play an important role in  
94 increasing PUFA.

95 We further surveyed the expression level of *FAD2* orthologues of six  
96 species in *Brassica* and found that *BcaFAD2.B1* had the highest expression,  
97 which had 89% of total orthologs expression in *B. carinata* (Supplemental  
98 Figure 9). In HLL45, three *FAD2* orthologues was expressed and mainly  
99 contributed by *FAD2.B1* with reaching its highest expression at 36 DAF, while  
100 *FAD2.C5* was not expressed in HLL45 (Figure 1I). *FAD2.A5* and *FAD2.C1* in  
101 HLL45 were both expressed at about the similar level as them in traditional *B.*  
102 *napus* ZS11, while *FAD2.B1* was expressed more highly than *FAD2.C5* in  
103 ZS11, which was confirmed by RT-PCR (Figure 1J). Except in seeds,  
104 *FAD2.B1* was also expressed in root, leaf and stem (Supplemental Figure 10).  
105 During the seed development, the PUFA content in HLL45 was higher than  
106 that of ZS11, especially LEI. After 18 DAF, the LEI content in HLL45 was  
107 higher than in ZS11, and the difference increased as the developmental time  
108 extends (Figure 1J and Supplemental Figure 11). Therefore, the increased  
109 PUFA content of HLL45 can be explained that *FAD2.C5* was replaced by  
110 *BcaFAD2.B1* with highly expressed level.

111 *FAD2.B1* was the nearest clade to *FAD2* in *A. thaliana* and had many  
112 sequences in promoter and enhancer within the 800bp upstream of gene,  
113 while *FAD2.C5* did not have (Supplemental Figure 12 A, B and Supplemental  
114 Table 9). Compared to *BcaFAD2.B1* and *BniFAD2.B1* with one exon,  
115 *BnaFAD2.C5* and *BoIFAD2.C5* had one additional exon encoding 73 AA and  
116 same conserved domain (Supplemental Figure 12C and 13). Besides,  
117 *FAD2.C5* in HLL45 (BnaHLLC05G045860) and *BcaFAD2.B1*  
118 (Bca4012B1G035280) had the same structure, but they both had almost

119 identical C-termini but distinct N-termini with *BnaFAD2.C5*  
120 (BnaC05G0480500ZS) (Supplemental Figure 12D).

121 High PUFA content of rapeseed oil is a desirable trait which has been  
122 unachievable using conventional germplasm. We have demonstrated the use  
123 of wild relative introgression to achieve this, implicating high expression of  
124 one of the *FAD2* orthologues from the B genome, which is not normally  
125 present in oilseed rape, as causative. Our study provides both evidence for  
126 how PUFA content in seed oil above the normally occurring range is controlled,  
127 and an example for others to follow of how to use genomics to accelerate use  
128 of wild relative introgression for crop improvement.

### 129 **Data availability**

130 The genome assembly have been deposited in the Genome Warehouse at  
131 the National Genomics Data Center, Beijing Institute of Genomics, Chinese  
132 Academy of Sciences/China National Center for Bioinformation, under  
133 accession number PRJCA025800. The genomic sequencing data and  
134 transcriptome sequencing data have been deposited in National Genomics  
135 Data Center (GSA: CRA016277) that are publicly accessible  
136 at <https://ngdc.cncb.ac.cn/gsa>.

143 Network (OREGIN) (CH0110).

**144 Author Contributions**

145 Y.N. performed the research, analyzed the data and wrote the paper. W.L.  
146 performed field trials, genetic mapping and QTL analysis. Y.Y. performed  
147 phenotyping, sampling and molecular marker analysis. H. W. and Y. Z.  
148 contributed to the genome assembly. J.Z and H.Q contributed to plant  
149 material development, cultivation, phenotyping, and QTL analysis. Z.H.  
150 performed GDTPs analysis. D.H. contributed to QTL and genome  
151 resequencing analysis. J. W. and C.Z. contributed to the design for RT-PCR  
152 and fatty acid composition analysis. G.Y. contributed to the design of field  
153 trials and revise the manuscript. J.Z. and I.B. designed the project, analyzed  
154 the data, and wrote the manuscript. All authors edited and approved the final  
155 manuscript.

198 **Figure 1 The exotic introgression on C5 in HLL45 from *B. carinata***  
199 **increasing PUFA content.**

200 **(A)** Large-scale homoeologous exchanges (HEs) of new-type *B. napus* HLL45  
201 identified by Genome Display Tile Plots. Red, black, orange, purple and green  
202 arrows represent HEs of A2/C2, A3/C3, A4/C4, C5/B1 and A9/C8,  
203 respectively.

204 **(B)** The upper figure represents the fatty acid component distribution for five *B.*  
205 *napus* accessions. LEI, LEN, OLE and EA mean linoleic acid content, linolenic  
206 acid content, oleic acid content and erucic acid content, respectively. The  
207 bottom figure represents the QTL mapping for fatty acid traits using HG DH  
208 populations (280 lines).

209 **(C)** The genomic features of exotic introgression in HLL45 (100 kb window). I-  
210 V means gene density, TE density, exotic gene density from BraA (*B. rapa*),  
211 BcaB and BcaC (B and C sub-genome of *B. carinata*).

212 **(D)** Pathway enrichment plot of exotic genes from BcaB in HLL45 (top 15).

213 **(E)** The volcano plot of 217 genes within the major QTL on C5 in seeds (40  
214 days after pollination). Compared to ZS11, most candidate genes in HLL45

215 were significantly up-regulated, especially BnaHLLC05G045860  
216 (*BcaFAD2.B1*).

217 **(F)** The collinearity of chromosome C5 among HLL45, *B. napus* Darmor-bzh  
218 and *B. carinata* C4012.

219 **(G)** The generation, transmission process and effect of SV on C5. Difference  
220 on linoleic acid (LEI) and oleic acid (OLE) content between lines with C5 SV  
221 and no SV from HG population. Statistical significance was determined by  
222 two-tailed unpaired Student's T-test.

223 **(H)** PCR validation for C5 SV and exotic gene *BcaFAD2.B1*. The left figure  
224 represents PCR genotyping assay for lines with different linoleic acid (LEI)  
225 content from HG populations on C5 SV markers. PCR amplicons of 211 bp  
226 and 577 bp represent the presence and absence of the SV, respectively. The  
227 left figure represents PCR genotyping assay for HLL45, HS3 and lines with  
228 different linoleic acid (LEI) content from HG populations on *BcaFAD2.B1*  
229 markers. PCR amplicons of 424 bp and 222 bp represent the presence and  
230 absence of *BcaFAD2.B1*, respectively.

231 **(I)** The gene expression pattern of three *FAD2* orthologues in different tissues  
232 and seed development in HLL45 and conventional *B. napus* ZS11 based on  
233 FPKM.

234 **(J)** The upper figure means LEI and LEN content in different seed  
235 development of new-type *B. napus* HLL45 and conventional *B. napus* ZS11.  
236 LEI means linoleic acid content and LEN means linolenic acid content. The  
237 bottom figure means the gene expression pattern of three *FAD2* orthologues  
238 in different seed development of HLL45 and conventional *B. napus* ZS11  
239 based on the relative expression level from RT-PCR.
